also has applications as a *thermite, in certain explosives,* and for *smoke screens.* In its manuf. a single-phase furnace is used, with a c. d. not exceeding 5 amp./sq. cm. of electrode cross section area. The reaction is: $2SiO_2 + 2C + CaC_2 = Si_2Ca + 4CO$. The slag density must be decreased to get good sepn. from the molten metal. Energy efficiency = 45%; 6000 kw.-hr./ton. C. F. Bonilla

1 **The Soderberg electrode in the aluminum industry.** Robert Sevin. *J. four élec.* **48**, 51–6(1939).—Since 1934 Al production in closed cells with the Soderberg electrode has increased from 20,000 to 175,000 tons/yr., now constituting 30% of all Al. The gases are led to towers with circulating soda soln. which dissolves the F. By adding AlF_3 to the decanted soln. $^3/_4$ of the cryolite requirement is regenerated. Lower voltage (4.5 to 5.3) is required, and the same purity maintained. C. F. Bonilla

2 **Effect of electrode spacing and current density in aluminum production.** Louis Ferrand. *J. four élec.* **48**, 129–32(1939).—German, Italian and French Al cells are compared. The Fr. use lower c. d. (1.16 amp./sq. cm. vs. 1.5 to 1.6), larger spacing between electrodes (5.7 cm. vs. 4.4 to 4.7), lower current efficiency (78% vs. 85 to 90%) and the same energy consumption (20 kw.-hr./kg.). New horizontal anode furnaces being built in these countries tend toward lower c. d. (0.85 to 1), and lower energy (13.9 to 16.4) consumption. C. F. Bonilla

3 **Chromium plating plastic molds.** Arthur W. Logozzo. *Monthly Rev. Am. Electroplaters' Soc.* **27**, 11–21(1940).—Metal molds for plastics are Cr plated for resistance to abrasive wear and corrosion. Cr has a low coeff. of friction which permits free extn. of the molded product from the mold. The min. thickness of Cr should be 0.001 in. A uniform coating of Cr is important. If the mouth of a deep slot is more heavily plated than the recess, a back taper results which prevents free removal of the plastic from the mold. Prior to plating, the mold must be highly polished. The mold is given an alk. cleaning and then an anodic treatment in a CrO_3 soln. It is Cr plated and the final Cr plate is polished. To secure a more even current distribution on the mold, inside anodes are used. The "octopus" anode is much used. It consists of a no. of Pb wires, about $^1/_8$ in. in diam., attached to a Pb-coated conducting bar. These wires can be placed so as to project into slots and recesses. A. Brenner

4 **Chromium plating dies and gages.** D. A. Cotton. *Proc. Am. Electroplaters' Soc.* June, **1939**, 61–7.—The Cr plating of molds for plastics considerably increases their life and prevents sticking of the product. Unplated molds are etched by the plastic. This is prevented by Cr plating. C. gives many examples of savings effected by salvaging worn or undersized parts with Cr plating. By Cr plating the rams of hydraulic presses, the wear on the leather packing was greatly reduced. Preparatory to Cr plating, all objects are given a 15–20 sec. anodic treatment in the Cr bath. Cr-plated parts which have been worn undersized are replated without stripping by use of the anodic treatment. However, if steel is exposed, all the Cr must be stripped before replating. A. Brenner

5 **Continuous electrodeposition of bright chromium at high speed on fine wires.** Albert Guerillot. *Proc. Am. Electroplaters' Soc.* June, **1939**, 37–8.—Cu wire, 0.06 to 0.07 mm. in diam., is plated with bright Cr for use in making "silver" braid. Ag-plated wire tarnishes too readily. The wire is passed successively through a tank of dil. HNO_3 (1:10,000), next through a rinse tank, then into the Cr plating tank and finally through another rinse tank. The rate of production is about 250 m. of wire per hr. from each coil. A. Brenner

6 **Electrodeposition of black molybdenum finishes.** R. A. Hoffman and R. O. Hull. *Proc. Am. Electroplaters' Soc.* June, **1939**, 45–9.—The black Mo finish is useful for decorative purposes and can be lacquered. This finish is produced in a bath contg. 4–5 oz. of $(NH_4)_2MoO_4$ and 3.5 oz. of $NiSO_4$ in a gallon of soln. The operating conditions are: pH = 4.3 to 4.7; temp. = 55° to 80°; cathode c. d. = 2 to 5 amp./sq. ft.; time = 8 to 10 min.; agitation is desirable. A deposit 0.001 in. thick is produced. The basis metal should be previously electroplated with Zn or Cd. Die-cast Zn or Al can also be coated with the Mo. The black coating consists of about 45% Mo, 10% Ni, and the remainder O. Its sp. gr. is about 1.01. The amt. of deposit obtained per amp. hr. decreases as the c. d. is raised. After 0.001 in. has been deposited, gassing begins and the rate of deposition considerably decreases. After 1 hr., deposition practically ceases, and the max. thickness of coating obtained is 0.002 in. The coating obtained on irregularly shaped objects is fairly uniform. The black coating flakes off on severe flexing. The coating is permanent in air. Applied directly to steel, it affords no protection against corrosion, but it increases the protective value of Zn coatings on steel. A. B.

7 **Notes on the adhesion of electrodeposited metals to steel.** A. W. Hothersall. *Proc. Am. Electroplaters' Soc.* June, **1939**, 1–7.—The adhesion of coatings to the basis metal is due to at. forces. Mech. interlocking may occur in some cases but contributes little to the strength of the bond. The existence of at. forces is shown by the well-known fact that some electrodeposited metals continue the crystal structure of the basis metal. Electrodeposited Ni continues the crystal structure of Fe for a short distance. The adhesion of Ni to various basis metals approximates the tensile strength of the metals. A thin oxide film on steel does not necessarily prevent good adhesion of Ni, as good adhesion was obtained on clean steel which had stood 2 days in a 100° oven. Although lack of proper cleaning of the steel is the usual cause of poor adhesion of Ni coating, a low degree of adhesion may result from weakness of the surface layer of the steel. Machined or emeried steel surfaces are weak and Ni coatings are readily detached from them. A little better adhesion is obtained on a polished steel surface. By heating the latter in H at 250° for 1 hr. before plating, good adhesion was obtained. Anodic etching of the steel in H_2SO_4 removes the weakened surface layer of machined or polished steel. The concn. of H_2SO_4 may vary from 30 to 80%. The steel rapidly becomes passive in the acid and the current drops. The steel dissolves with a current efficiency of about 20% even while passive. A. B.

8 **Stress in electrodeposited copper as determined by x-rays.** Elbert M. Mahla. *Trans. Electrochem. Soc.* **77**, 11 pp.(preprint)(1940).—The relative amt. of stress in deposits of Cu made at different temp. and c. d. was detd. by the measurement of the elongation of the spots on a Debye-Scherrer transmission x-ray film relative to their width. Stress was plotted against c. d. and temp. in a 3-dimensional diagram. In deposits made at low temp., temp. was shown to be a greater factor than c. d. in detg. the stress, while at high temp. c. d. was the principal factor. No direct relationship between hardness and stress was observed. C. G. F.

9 **The application of x-ray diffraction analysis to electroplating problems.** Herbert R. Isenburger. *Proc. Am. Electroplaters' Soc.* June, **1939**, 77–83.—A review. A. Brenner

10 **X-ray investigation of electrolytic zinc deposits.** G. F. Kosolapov and B. Yu. Mett. *J. Tech. Phys.* (U. S. S. R.) **9**, 1421–4(1939).—The anisotropy of Zn deposited from a cyanide bath increases with c. d. between 1 and 7 amp./sq. dm. and with the thickness of the deposit; it decreases with rising temp. and c. d. between 7 and 14 amp./sq. cm. It is lowered by stirring and not affected by addn. of glycerol. The luster of Zn deposits increases with their anisotropy. J. J. Bikerman

11 **Microscopic and drop-test methods on metallic electrodeposits.** J. W. Higgins. *Am. Soc. Testing Materials, Bull.* No. 100, 21–4(1939).—The microscopic method of detg. the thickness of Cu or Ni deposits with a filar micrometer and drop tests for detg. the thickness of Zn, Cd and Cr coatings are briefly outlined. Details of specimen prepn., compn. of test solns., etc., are given. Leopold Pessel

12 **The chemical determination of local thickness of electrodeposited metallic coatings by the B. N. F. jet-test.** S. G. Clarke. *Proc. Am. Electroplaters' Soc.* June, **1939**,

24–30.—Further improvements were made in the jet-test (*C. A.* **31**, 2568[8]). A modified reagent (labeled "FC") has been proposed for testing Cu, Ni, Co and bronze coatings. This soln. has the following compn.: $FeCl_3.6H_2O$, 300 g./l.; $CuSO_4.5H_2O$, 100 g./l. It supersedes soln. "1A" (contg. HCl and AcOH in addn. to the above salts) which had been found to be somewhat unstable. It dissolves Ni somewhat faster than the "1A" soln. Curves are given for the rate of penetration of coatings as a function of temp. The details of the method are essentially as given in *C. A.* **31**, 2568[9]. A. Brenner

Experiments on the distribution of electrodeposits on a cup-shaped cathode. G. E. Gardam. *Proc. Am. Electroplaters' Soc.* June, **1939**, 16–22.—The metal distributions obtained in Ni, Sn, Cd, Cu, and Cr plating baths were detd. on hemispherical bowls, 2 in. in diam. The local thickness of plating was detd. by the B. N. F. jet method. The av. thickness of coating in each test was about 0.0006 in., but all results were calcd. to the basis of an av. thickness of 0.001 in. for the cup. Some knowledge of the primary current distribution on the bowl can be obtained from Maxwell's equation for a freely charged hemispherical bowl. In practically all cases the metal distribution was more uniform than the primary current distribution. The expts. showed that a more uniform metal distribution was obtained at low c. d. in Ni baths and $CuSO_4$ baths. Increase of temp. and agitation decreased the proportion of metal going to the inside of the bowl. The bright Co-Ni baths, contg. formaldehyde, gave a poorer metal distribution than the ordinary Ni bath, but the sulfonate bright Ni gave about the same metal distribution. The cyanide Cd, cyanide Cu, and acid tin baths gave more than twice as much metal on the inside of the bowl at the bottom as did a $CuSO_4$ bath. Various geometrical factors, such as position of the bowl in the tank, arrangement of anodes, size of tank, etc., had only a small effect on the metal distribution. A. Brenner

The role of diffusion in electroplating processes. J. T. Burt-Gerrans. *Proc. Am. Electroplaters' Soc.* June, **1939**, 39–42.—A review. A. Brenner

External heating of plating solutions. Dale Augsburger. *Monthly Rev. Am. Electroplaters' Soc.* **27**, 23–8 (1940).—See *C. A.* **33**, 5750[8]. A. Brenner

Recent developments in British plating practice. C. Francis-Carter. *Proc. Am. Electroplaters' Soc.* June, **1939**, 9–16.—The subjects reviewed are: bright Ni plating, bright Zn plating, the Rochelle salt Cu cyanide bath, vapor and solvent degreasing, filtration, the use of rubber tank linings, rectifiers and plating specifications. A. Brenner

Electrodeposition in France. M. Ballay. *Proc. Am. Electroplaters' Soc.* June, **1939**, 30–6.—Electroplating practice in France is similar to that in the U. S. A. A. Brenner

Theoretical training for the electroplating industry. J. U. MacEwan. *Proc. Am. Electroplaters' Soc.* June, **1939**, 43–5.—A discussion. A. Brenner

Determining film thickness with the recording spectrophotometer E. Q. Adams and L. S. Ickis, Jr. *Gen. Elec. Rev.* **42**, 450–1(1939).—Films on anodized Al reflectors were measured under the microscope equipped with a micrometer eyepiece, with a precison of about 10%; and then by the spectrophotometer, which appears the more accurate of the 2 methods. With the spectrophotometer, results are exactly reproducible and represent the av. conditions for an appreciable area of the sample. C. G. F.

An electron-diffraction study of anodic films. R. A. Harrington and H. R. Nelson. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. **1158**, 14 pp. (1940).—Al anodized at room temp. usually gave diffuse patterns. Anodic films formed on Al in a wide variety of electrolytes at ordinary temps. are amorphous. Anodic treatment in solns. at higher temps. tends to produce anodic films having less random structure. Heating the anodic film on Al at temps. up to 650° does not appreciably change its structure, although cryst. oxidation products are formed on unanodized Al at temps. above about 300°. Depending on certain conditions, anodic films formed on Ta and Ti are at least partly cryst. or are amorphous. Immersion of anodized or unanodized Al in water at temps. above 80° produces a thin layer of böhmite (α-$Al_2O_3.H_2O$). A film produced in this way is transformed to γ'-Al_2O_3 at temps. around 650°. Immersion of metallic Al in boiling chem. solns. gives definitely cryst. films, in contrast to the usual results with anodic treatment. C. L. Mantell

The cathodic behavior of zinc relative to iron in hot water. Gerhard Schikorr. *Gas- u. Wasserfach* **82**, 834–7 (1939).—See *C. A.* **33**, 7671[6]. R. W. Ryan

The refining of monel scrap by oxidation with water. Keeiti Ota. *Nippon Kinzoku Gakkai-Si* **3**, 425–8(1939).—On the assumption that a violent oxidation will remove C and Si from molten monel scrap, the metal was treated in a high-frequency elec. furnace with water or steam as oxidizing agent. The results of expts. were fully satisfactory. H. Nishimura

Single potential of pure aluminum. II. Isamu Igarasi and Kiyoiti Kodama. *Nippon Kinzoku Gakkai-Si* **3**, 428–30(1939).—The single potential of pure Al was measured by the direct-reading method with the aid of vacuum tube Ux-54. Thus const. values were obtained, E_H = 1.22 v. for 99.99% Al, E_H = 0.81 v. for 99.8% Al, in *N* KCl soln. at 25°. The local elements on the specimen have marked effect on its electrode potential immediately after being placed in the soln. By bubbling O through the KCl soln., the potential of 99.99% Al was temporarily decreased and then immediately increased. The exptl. results indicated that the change in potential by bubbling gas into the soln. is not due to formation of a gas-metal electrode, and the surface condition of the sample has considerable effect on its potential; the smoother the surface of the sample, the more basic it is. Cf. *C. A.* **32**, 8954[3]. H. Nishimura

The polarization of the electrolytic hydrogen evolution on alloys of nickel with iron and cobalt in alkaline solution. G. Grube and U. Croatto. *Z. Elektrochem.* **45**, 815–20 (1939).—The effect of the surface on polarization at a Ni cathode was measured in 6 *N* KOH for increasing and decreasing c. d. A highly polished surface gave higher values for the cathodic potential than roughened surfaces. The time change of the potential at polished and roughened Ni cathodes and at roughened Fe cathodes was found to depend on the surface; for polished Ni the increase is more rapid and the end value reached sooner than for rough Ni. Curves are given showing the relation of the cathode potential to the c. d. for Ni-Co alloys contg. 100, 30, 20, 10, 5, 0% Ni and for Ni-Fe alloys contg. 100, 80, 60, 40, 20, 0% Ni. The mixed crystals in the region of the face-centered cubic structure of Ni-Co show little effect on polarization; above 70% Co in the region of hexagonal mixed crystals the effect is pronounced. No sharp effect corresponding to a phase change was found in the Ni–Fe system. H. C. Thomas

Photoelectric cells sensitive to long wave length radiation. The bismuth sulfide cell. Colin G. Fink and Johnstone S. Mackay. *Trans. Electrochem. Soc.* **77**, 27 pp.(preprint)(1940).—A Bi_2S_3 photoelement having a threshold wave length of 50,000–80,000 A. was developed and studied. This threshold wave length is higher than any yet recorded for other photoelements. Approx. 80% of the cell's spectral activity is beyond the visible region, whereas cells now in com. use are sensitive primarily in the shorter or visible wave lengths. The total photoelec. sensitivity of the Bi_2S_3 cell compares favorably with that of the vacuum tube photoelec. cells, being much greater than that of the Na and about the same as that of the Cs cell. The unipolar cond. of the exptl. Bi_2S_3 cell is very small, but when the cell is further developed so as to give unipolar conductance much quicker and higher response is expected. The cell is applicable as the basis of temp. control in low-temp. systems. C. G. F.

Heat-transfer methods in arc interruption. C. G. Suits. *Gen. Elec. Rev.* **42**, 432–5(1939).—The elec. char-

acteristics of arcs burning in various gases were measured. For common gases the relation E = const. I^{-n} where n lies between 0.5 and 0.7 and E is the gradient in v./cm. This is probably one of the most fundamental elec. aspects of the steady-state arc. A second important aspect is the pressure effect. In all gases the gradient, E, increases with increase in gas pressure, but this increase in E is small. Thus, N_2 pressure must be increased 10-fold to double E. Gases studied are N_2, A, He and H_2. For these E = const. p^m where m ranges between 0.16 and 0.31. A third fundamental is the gas effect. E varies greatly from gas to gas. To produce a similar change in a single gas would require enormous pressures. Thus, E at an arc current of 10 amp. is 5 v./cm. for Hg vapor, 8.5 for A, 22 for N_2, 32 for He and 90 for H_2. Any factor that changes E likewise changes I, the c. d. For N_2, E = const. $p^{0.31}$ and I = const. $p^{0.80}$. For a 10-amp. arc current and 1 atm. I = 5.7/sq. cm. for N_2; 570 for H_2. The elec. properties of an arc in a given gas can be duplicated in any other gas. H_2 at 1 atm. behaves like N_2 at 110 atm. because then the convection heat loss of N_2 is equal to that of H_2. The elec. properties of the arc are detd. by the thermal properties of the gas. Arcs in gases have the same elec. properties at the pressures for which the convection heat transfer is the same. The electrons in the arc column are in thermal equil. with the arc gas. Electron temp. and gas temp. are sensibly the same: the energy transfer between electrons and gas mols. is almost perfect. Sudden cooling will interrupt the arc—on which certain circuit-interruption devices are based. C. G. F.

Restriking phenomena of arcs. S. Horikosi. *Electrotech. J.* (Japan) **3**, 280–6(1939).—Expts. were made with a. c. arcs between Cu electrodes; the phenomena were recorded with the aid of a high-speed light switch and Kerr cell (Dunnington, *Phys. Rev.* **38**, 1506(1931)), with a high-speed camera and with a cathode-ray oscillograph. Restriking may be due to ionization by collision or to thermal ionization. Extinction of arc was accomplished in 2 ways: sudden cooling; or, increasing the heat capacity of the surrounding medium (oil is substituted for air). When thermal breakdown occurs, the diam. of the arc column is large and the temp. rises gradually. When breakdown is due to ionization by collision, a narrow, hot arc column, just like a spark, appears. C. G. F.

The gettering powers of various metals for the gases hydrogen, oxygen, nitrogen, carbon dioxide and air. Louis F. Ehrke and Charles M. Slack. *J. Applied Phys.* 11, 129–37(1940).—Measurements were made on Al, Mg, Th, U, misch metal (Ce and La), Zr and Ba as getters in the absence of elec. discharges or other sources of ions. The superior powers of diffuse layers as compared to those of bright layers were confirmed. Ba and misch metal were the most active, but Ba is not effective in the presence of Hg vapor. Mg and Al showed little activity in the absence of a discharge. Th and U showed considerable activity for H and O but the high temp. necessary for flashing makes these inconvenient to use. S. L. G.

Reignition voltage characteristics of grid-controlled discharge tubes. Y. Watanabe and Y. Nakamura. *Electrotech. J.* (Japan) **3**, 243–6(1939).—Expts. were made on hot-cathode and on Hg-pool-cathode rectifier tubes. The characteristic reignition voltage is best represented by $V_r = V_0 + kt^n$ where V_0 is the ionization voltage, t the time and k and n are consts. C. G. F.

Color of the light from alloy lamps. T. Asada and H. Yosinaga. *Electrotech. J.* (Japan) **3**, 247–50(1939).—Metal-vapor discharge lamps were made by use of Zn-Cd and Cd-Hg in place of Hg of the standard lamp. These metals do not attack quartz. It was found that the compn. of the alloy vapor arc could not be predetd. from the single vapor pressures. Increasing the voltage may increase the intensity of that component having the lower vapor pressure. C. G. F.

Spectral distribution of radiation from lamps of various types. B. T. Barnes, W. E. Forsythe and W. J. Karash. *Gen. Elec. Rev.* **42**, 540–3(1939).—Spectral intensities over the range 2200 to 26,000 A. for lamps of various types measured with a quartz double monochromator. The percentage of overall input radiated in the visible range (3800–7600 A.) is 7.9 for the 260-watt Na vapor lamp; 9.8 for 415-watt Ne; 9.3 for 456-watt Hg in glass; 14.3 for 1170-watt Hg in quartz; 12.4 for 17.5-watt fluorescent (daylight color); 14.8 for 17.5-watt fluorescent (blue color); 9.6 for 100-watt W vacuum (2865°K.); 17.4 for 1000-watt W photoflood (3360°K.). C. G. F.

Fluorescent lamps and their applications. A. B. Oday and R. F. Cissell. *Trans. Illum. Eng. Soc.* (N. Y.) **34**, 1165–88(1939).—Because of high luminous efficiency and low percentage of radiant energy, the lamps are particularly suitable for producing high levels of illumination with resultant cool foot candles. The fluorescent materials used in the lamp are particularly sensitive to middle ultraviolet (2000 to 3000 A.). About 1/3 the energy input goes into the 2537 A. unit line at the center of the middle ultraviolet region. Less than 2% of the energy is represented in the visible Hg lines. Part of the energy is consumed in keeping the electrodes hot to insure the free emission of electrons. The 13% of the energy that is converted into visible, useful light is higher than is obtained from filament lamps of comparable light output. Combination of the higher efficiencies of fluorescent lamps with the lower percentage of radiant energy results in the radiant heating effect per foot candle being only 1/4 that from incandescent W lamps. Synthetic "phosphors" are so prepd. as to have their max. excitation sensitivity in the vicinity of 2537 A. In addn. to the "phosphor," a Mn salt is usually present as an activator. Among the fluorescent materials used, the emitted range and emitted peak are: $CaWO_4$ 3800–7000 A.; 4400 A.; $MgWO_4$ 3800–7200; 4800; Zn silicate 4500–6200; 5250; Zn Be silicate 4500–7200; 5950; Cd borate 4000–7200; 6150. In general, the voltage drop at each electrode is 12 to 18 v. The drop across the lamp, when operating, is about 2/3 of the total supply voltage. The useful life of the lamps is over 2000 hrs. For a 1-in. diam. glass tube, 18 in. long, the ratings are 15 w., nominal lamp amp. 0.30; nominal lamp v. 56; circuit voltage 110–125. The power factor is about 90%. Details for other sizes are given. C. G. F.

Developing methods for prepn. of red lead from galena answering requirements of storage-battery industry (Sakharova, Levitina) **18** Use of glass electrode in biol. lab. (Holden) **11B**. Ni-Cd alloys [for elec. contacts] (U. S. pat. 2,182,380) **9**. Fluorescent screen for cathode-ray tube (U. S. pat. 2,182,860) **3**. Device for elec. heating of used lubricating oil in still (U. S. pat. 2,181,484) **22**. App. for immersing articles in plating baths (Brit. pat. 508,246) **1**. Elec. contacts (U. S. pat. 2,182,381) **9**.

Lead oxide-sulfate storage-battery plate compositions. James O. Johnstone (to Glidden Co.). U. S. 2,182,479, Dec. 5. A substantially dry compn. suitable for making battery pastes comprises particles of a Pb oxide carrying a coating of basic Pb sulfate equiv. to a 5–15% content of normal Pb sulfate.

Microporous battery separators of hard rubber. Eardley Hazell (to United States Rubber Products, Inc.). U. S. 2,181,891, Dec. 5. A microporous battery-plate separator of vulcanized hard rubber is formed with the longitudinal grain characteristic of calendered rubber and with the rubber phase continuous and forming at least about half of the separator by wt., the rubber being intimately assocd. with dispersed finely divided cellulosic material such as 40 mesh cellulose flock and colloidal clay ingredients.

Microporous diaphragms suitable for storage-battery separators. Wm. J. Burgess (to Electric Storage Battery Co.). U. S. 2,181,299, Nov. 28. Diaphragms of good strength and resistant to electrolytic oxidation are made by a process which involves mixing latex with a hydrophillic colloid and with S in sufficient quantity for vulcanization to hard rubber, drying the mixt. until the moisture content is reduced to about 5%, consolidating the material by pres-

sure, wetting the consolidate mass, and vulcanizing in the presence of moisture to obtain a product of high electrolytic permeability.

Electrolytic condenser. Joseph A. Poitras (to Solar Mfg. Corp.). U. S. 2,181,607, Nov. 28. Structural details of a rubber bushing, etc.

Electrolytic condenser. Cornelis de Lange and Adriaan J. J. Lambeek (to N.-V. Philips' Gloeilampenfabrieken). U. S. 2,183,092, Dec. 12. Structural details.

Electrical condenser. Frederick J. Given (to Bell Telephone Laboratories, Inc.). U. S. 2,181,695, Nov. 28. Various mfg. details in the use of materials such as Al foil, paper and Pb foil.

Electrolytic cell suitable for use as a wet condenser. Anthony F. P. J. Claassen and Cornelis de Lange (to N.-V. Philips' Gloeilampenfabrieken). U. S. 2,183,091, Dec. 12. Various structural details.

Electrolytic capacitors. Donald E. Gray (to Cornell-Dubilier Corp.). U. S. 2,182,376, Dec. 5. In the manuf. of an electrolytic capacitor, a metal foil such as a foil of Al is passed through a soln. of electrolyte (such as one formed from B_2O_3, NH_4OH and glycerol) of comparatively thick consistency at such a rate as to produce a thick and uniform coating of electrolyte on the foil, an uncoated fibrous spacer such as one of paper or cloth is applied to the coated foil under controlled pressure serving to impregnate the spacer with the coating and to remove excess electrolyte, and the foil and spacer are wound with associated capacitor elements into a supply roll from which the wound material may be withdrawn in units for individual capacitors as desired. App. is described.

Electroplating metals such as steel, etc., with brass. Christian J. Wernlund (to E. I. du Pont de Nemours & Co.). U. S. 2,181,773, Nov. 28. An electroplating process is employed which involves electrolyzing a soln. contg. Zn and Cu cyanides and an alkali metal hydroxide, the ratio of the concn. of Zn cyanide to the concn. of the hydroxide in the soln. being maintained chemically equiv. to a Zn cyanide to caustic soda ratio of approximately 1.1, the concns. being expressed as wt. of solute per unit vol. of solvent, and maintaining the soln. at a reasonably const. temp., so as to maintain a substantially const. compn. of electrodeposit when changes occur in the c. d.

Apparatus for electroplating, as with copper. Charles W. Lowe (to Electrical Research Products, Inc.). U. S. 2,181,490, Nov. 28. Various structural and operative details of an app. with rotating electrodes used with a circulating electrolyte.

Chromium plating. Frank H. Beall. U. S. 2,182,214, Dec. 5. A low-etching Cr plating bath for plating clear, adherent Cr comprises an aq. soln. of chromic acid, in part free and in part combined as an alkali salt, the free acid constituting 20–40% of the total, and not less than approx. 5 oz. per gal., and sulfate to the amount of not over approx. 0.4% of the total chromic acid (the total chromic acid being 30–50 oz. per gal.).

Electroprocessing apparatus suitable for cleaning and plating, etc. Guerin Todd (to Hanson-Van Winkle-Munning Co.). U. S. 2,182,184, Dec. 5. Various structural, mech. and operative details.

Cores for use in electrodeposition of pipe couplings. Alfred C. Arbogast (to Northern Indiana Brass Co.). U. S. 2,181,256–7, Nov. 28. Various structural details.

Copper-coated lead powder. Charles L. Mantell (to Hardy Metallurgical Co.). U. S. 2,182,567, Dec. 5. An arrangement of app. is described, and a process for the manuf. of Pb particles with a Cu plating upon them which involves passing a d. c. through an aq. acetate electrolyte contg. HOAc and relatively large proportions of Cu and Pb in soln. in an electrolytic cell contg. a cathode, a lead anode, and a copper anode, maintaining the cathode c. d. in excess of that at which lead deposits from the electrolyte in massive form so that the lead deposits from the electrolyte as substantially nonadherent fine particles and the particles become plated with Cu from the soln. and controlling the ratio of Cu to Pb in the resulting Cu-coated Pb particles by varying the ratio of exposed Cu per anode surface in the soln. to exposed Pb anode surface in the soln.

Hydrogen peroxide. Gustav Adolph and Max E. Bretschger (to Buffalo Electro-Chemical Co., Inc.). Can. 386,573, Jan. 30, 1940. Bisulfate-H_2SO_4 acid soln. is electrolyzed and distd. The distn. residue is cooled until a pasty crystal mass of H_2SO_4 and bisulfite is obtained, the crystals are sepd. from the acid, the acid is purified, the purified H_2SO_4 is added in proper amt. to the electrolyzed soln. of the sepd. crystals and the mixt. is distd.

Electric induction furnace. David Pisarev. U. S. 2,182,819, Dec. 12. Various structural, elec. and operative details. U. S. 2,182,820 relates to details of an induction heating coil.

Induction furnaces. The British Thomson-Houston Co. Ltd. Brit. 508,255, June 28, 1939. Means for regulating the magnitude and(or) the phase position of the voltages feeding the furnace windings to any extent with regard to each other in a 2- or multi-phase coreless induction furnace is described.

Induction furnace suitable for heating strip metal in a coil. Ernest G. Schlup (to American Rolling Mill Co.). U. S. 2,181,921, Dec. 5. Various structural details.

Apparatus for electrothermal decomposition of oil to produce carbon black. Victor F. Hanson (to E. I. du Pont de Nemours & Co.). U. S. 2,181,759, Nov. 28. Various structural, elec. and operative details.

Apparatus for irradiating foods, etc. Orrick H. Biggs (to Hygrade Sylvania Corp.). U. S. 2,181,293, Nov. 28. An app. is used including the combination of an ultraviolet lamp comprising tubular envelope of Corex glass transmitting radiations at 2537 A., an atm. of inert gas such as Ne or He at low pressure and Hg vapor within the envelope, electrodes about 2 in. apart and within the envelope at each end, app. for operating the lamp at a c. d. of 40 milliamps. per sq. cm., a refrigerating chamber around the lamp, a door in the refrigerating chamber, means actuated by the closing of the door for starting the operation of the lamp, and means to extinguish the lamp after a predetd. interval.

Device for rectifying high alternating voltages. Frans M. Penning (to N. V. Philips' Gloeilampenfabrieken). U. S. 2,182,736, Dec. 5. Various structural, elec. and operative details.

Light-sensitive electric device. Foster C. Nix (to Bell Telephone Laboratories, Inc.). U. S. 2,181,494, Nov. 28. A photo-e. m. f. cell is used comprising a metal base such as a Ni or Cu disk, a Tl member such as a film adjacent to and in contact with such metal base, and a film of Tl and S on the face of the Tl member remote from the base.

Electrostatic precipitator for gas purification Edward H. R. Pegg (to Westinghouse Elec. & Mfg. Co.). U. S. 2,181,147, Nov. 28. Various structural, elec. and operative details.

Electrostatic precipitator for gas purification. Gaylord W. Penney (to Westinghouse Elec. & Mfg. Co.). U. S. 2,181,767, Nov. 28. Various structural, elec. and operative details.

Reflectors. Egbert Gowlland. Brit. 508,205, June 28, 1939. Reflectors of high light-reflecting efficiency are made by forming on a support, e. g., of glass, a thin opaque metallic backing, preferably of nonoxidizable metal, e. g., Ge, Cr, Rh, and thereafter forming thereon a thin layer of Al. The metals are evapd. electrically in a highly exhausted chamber to deposit on the support and backing.

High-voltage ionic electrical discharge device. John G. Trump (to Research Corp.). U. S. 2,182,185, Dec. 5. Various structural, elec. and operative details.

Exhaustion of a photoelectric tube. Harvey C. Rentschler and Donald E. Henry (to Canadian Westinghouse Co. Ltd.). Can. 386,837, Feb. 13, 1940. A sealed, evacuated envelope is finally exhausted by connecting it to a refrigerated bulb contg. degasified charcoal.

Gaseous electric discharge devices of the positive column type. Hans Alterthum and Arved Lompe (to

General Elec. Co.). U. S. 2,182,776, Dec. 12. Various details of a device having a gaseous atm. contg. Ne together with A and a vaporizable material such as Hg. U. S. 2,182,777 also relates to a device contg. Ne and A. U. S. 2,182,778 (Hans Alterthum, Arved Lompe and Kurt Wiegand, joint inventors; to same assignee) also relates to a device which contains Ne, A and Hg. U. S. 2,182,779 (Hans Alterthum and Arved Lompe, joint inventors; to same assignee) relates to a device contg. Ne together with Kr or Xe and Hg. U. S. 2,182,780 also relates to a device contg. Ne, Kr or Xe and Hg. Cf. *C. A.* **34**, 9484.

Electric discharge lamp. Gilles Holst (to Canadian General Electric Co., Ltd.). Can. 386,576, Jan. 30, 1940. A hygroscopic material, e. g., C, is placed between a gaseous elec. discharge lamp and a removable and transparent enclosing container to avoid changes in the starting voltage of the lamp.

Electric discharge lamp with a filament of the oxide-coated coiled-coil tungsten wire type. Orrick H. Biggs (to Hygrade Sylvania Corp.). U. S. 2,181,294, Nov. 28. Various structural, elec. and operative details.

Metal-vapor lamps such as mercury-vapor lamps suitable for ultraviolet irradiation. Friedrich Meyer, Hans-Joachim Spanner and Edmund Germer (to General Elec. Co.). U. S. 2,182,732, Dec. 5. Various details of a lamp which may contain a rare gas under low pressure with metal vapor.

Fluorescent lamp. Henry W. Myers (to Hygrade Sylvania Corp.). U. S. 2,181,305, Nov. 28. The interior of the glass envelope of an elec. gaseous discharge lamp is coated with a luminescent material formed of 65 parts of Mn-activated Cd borate of a grain size less than 10 microns, 170 parts of Mn-activated Mg tungstate of a grain size less than 10 microns and 140 parts of a Zn Be silicate of a grain size less than 10 microns, the Zn Be silicate initially comprising ZnO 50, Be oxide 12, SiO_2 36 and Mn fluoride 2%.

Incandescent lamp. Wilhelm Röver. U. S. 2,182,904, Dec. 12. A lamp suitable for use to avoid visibility by aircraft is provided with a filament adapted to maintain an operating temp. below 1600° when fed from a lighting circuit of standard voltage, and a coating of white lacquer is applied to the exterior surface of the bulb, with an overlying coating of black lacquer, the coatings covering substantially the major portion of the bulb except for a small free portion or "window."

Electric incandescent reflector lamp. Orrick H. Biggs and Stuart S. Davis (to Hygrade Sylvania Corp.). U. S. 2,181,295, Nov. 28. Various structural details.

Electric incandescent lamps with reflector bulbs. Orrick H. Biggs (to Hygrade Sylvania Corp.). U. S. 2,181,291, Nov. 28. A sealed glass bulb has part of its inside surface coated with a light-reflecting layer of substantially pure Al over which is placed a transparent protective artificial coating of Al oxide, a wire filament being mounted within the Al-coated portion of the bulb and the bulb being filled with A at a pressure above half an atm. U. S. 2,181,292 also relates to various details of a bulb provided with a reflecting coating.

5—PHOTOGRAPHY

E. R. BULLOCK

The platinum process. Colin N. Bennett. *Home Photographer* **7**, 289, 312(1939).—A method of prepn. and processing of platinotype and palladiotype papers suitable for amateur use is described. Platinotype paper has about twice the speed of printing-out papers, and the prints are as permanent as the base on which they are made. R. F. W. Selman

The photographic emulsion and its contribution to science and industry. Olaf Bloch. *J. Inst. Metals* **64**, No. 1, 35–56(1939). E. H.

Anomalous dilution effects with trisodium phosphate as developer alkali. P. C. Smethurst. *Brit. J. Phot.* 86, 275–6(1939).—With the M. C. M. 100 developer (*C. A.* **32**, 5715[1]), diln. with H_2O must be to 10 times its vol. to obtain only the same d. in a given time from a given exposure as is obtained with the full-strength developer in half the time. R. B. Willcock. *Ibid.* 291–2; cf. *C. A.* **33**, 9164[9]. P. C. Smethurst. *Ibid.* 319–20. H. E. Durham. *Ibid.* 352. Discussion. A. M.

Substitution of dyes for the silver of photographic images and the fixation of dyes on gelatin in order to obtain negative or positive images. A. Seyewetz. *Bull. soc. franç. phot.* [4], **1**, 1–5(1939).—See *C. A.* **33**, 6179[4]. C. L. B.

Contrast relations of the image in photography through turbid media. Maximilian Plotnikov. *Phot. Korr.* **75**, 138–45(1939).—The effect of variation in wave length of the exposing light on the definition of test objects photographed through certain cloudy materials has been investigated. The exposures were made on one of 5 brands of dye-sensitized plates, for simultaneous development with controls in a M-Q developer. The turbid media were: soap soln., colloidal S solns. and gelatin soln., all contg. particles of (presumably) very small size; Agfa Isopan FF film; dild. milk; and NH_4Cl fumes, and tobacco smoke. Except with the 3 last, a considerable and progressive improvement in contrast is seen on passing from the near ultraviolet at around 380 mμ, through the visible colors, to infrared at around 900 mμ. The dild. milk shows longitudinal scattering (J. Plotnikov, *C. A.* **26**, 929), and no improvement, on the whole, in definition of the image between blue and infrared. NH_4Cl and tobacco clouds, possibly because they consist of relatively large particles, show, also, no very appreciable improvement with increasing wave length. P. describes, in conclusion, a preliminary attempt to express numerically (for the Agfa film) the variation of contrast with wave length. E. R. Bullock

The sensitometry and exposure determinations for infrared photographic plates. A. Petrikalns and J. Bungs. *Acta Univ. Latviensis, Kim. Fakultat. Ser.* **4** (in Lettish, 369–402; in German, 403–4)(1939).—For the study of plates used in civilian and military aerial photography P. and B. describe a modified Scheiner sensitometer with 21 stages and an exposure ratio of 1:100. They used a light from an Osram DIN-sensitometer lamp passed through a Schott filter RG 8 (2 mm.) and BG 17 (3 mm.), and measured the sensitivity of several films with a Thallofide cell connected with a compensating voltmeter. In field measurements during April and May the intensity of the infrared rays and the blue rays was measured; the intensities of these spectral ranges did not bear any relation to each other. Frank Maresh

Sensitometry of photographic papers. Loyd A. Jones and Charles A. Morrison. *J. Franklin Inst.* **228**, 445–70, 605–22, 755–69(1939).—The fundamentals, principles and methods of the sensitometry of photographic papers established by Jones, Nutting and Mees (*C. A.* **9**, 762–3) in 1914 are reviewed. The necessity for the use of intensity-scale exposure rather than the older time-scale methods is shown. An account of the evolution of the design of an optical wedge sensitometer which fulfills the required sensitometric specifications leads to the description of a new instrument used in this study of the sensitometric characteristics of photographic papers. Details of the complete sensitometric process are given. The resultant characteristic curves from the different types and grades of papers are described and interpreted. The typical characteristic curve of modern papers is discussed and a revised method of detg. numerical values, which describe the curve for practical purposes, is given. The new interpretation of the shape of the shoulder region of the curve is significant with respect to the quality of tone reproduction. The new group of characteristic values—

speed, max. gradient, exposure scale, max. —is defined and discussed. Numerical values obtained by the new sensitometric method are given in tabular form for most of the current types and grades of photographic papers. Authors

Transferring photographic designs to ceramic ware (U. S. pat. 2,181,452) 19.

Henney, Keith, and Dudley, Beverly: Handbook of Photography. New York: McGraw-Hill Book Co. 871 pp. $7.50.

Saint-Genies, Jacques de L.: Note sur l'optique des films gaufrés. Application à la cinématographie en couleurs. Paris: Éditions de la Revue d'optique théorique et instrumentale. 92 pp.

Color photography. Eastman Kodak Co. Brit. 507,841, June 19, 1939. Color-developed reversed images are produced in a photographic element such as described below and contg. developed neg. and undeveloped pos. images of Ag halide by a process that includes the steps of exposing and color-developing the pos. image in one or both of the outer layers and exposing the residual Ag halide in the middle emulsion layer by means of visible light passed through the outer emulsion layer or layers contg. the color-developed pos. Ag-plus-dye image in addn. to the developed neg. Ag image, color-developing the exposed residual Ag halide in the middle emulsion layer and removing the pos. and neg. Ag when the residual Ag halide has been exposed and color-developed in all the emulsion layers. The element is one having 3 Ag halide emulsion layers inseparably coated on the same side of a single support of which one of the outer emulsion layers is not specially color sensitized while the other outer emulsion layer and the middle emulsion layer are selectively color-sensitized, one being sensitized to the red region and the other to the green region of the spectrum. The not specially color-sensitized layer is destined to record the blue component image and may be adjacent to the support or farthest from it. Preferably the color-developed reversed images are produced in an element as described and contain neg. Ag images and undeveloped images of Ag halide in all the emulsion layers by first exposing the residual undeveloped Ag halide in one of the outer layers alone by means of visible light and color-developing it, then exposing the residual undeveloped Ag halide of the middle emulsion layer alone by means of visible light passed through such first exposed and color-developed outer emulsion layer and then color-developing it, then exposing the residual undeveloped Ag halide of the outer emulsion layer and color-developing it and finally removing the neg. and pos. Ag to leave the transparent pos. dye images in the layers. The element may be one in which the color sensitizer in the outer emulsion layer that is color sensitized is resistant to development, the residual Ag halide in such layer being first exposed alone by means of light to which it is selectively sensitized and color-developed. The element may have an antihalation layer on one or both sides of the support which is removable together with the metallic Ag and permits exposure of the residual halide of the bottom layer (and middle layer if necessary) through the support. The antihalation layer may be one contg. Ni sulfide, preferably in a gelatin or like layer. The antihalation layer may be between the emulsion(s) and the support, which may consist of a cellulose ester, paper or the like.

Photographic materials with antihalation layers. Geo. A. Dawson (to Du Pont Film Mfg. Corp.). U. S. 2,182,794, Dec. 12. A transparent support with a coating of sensitized material on one side is provided on the other side with a layer contg. a polymeric material contg. amino N such as piperidylmethylzein which is insol. in water and 5% NH_4OH soln. but sol. in dil. HOAc, and an antihalation dye. Numerous examples are given.

Light-filter layers. I. G. Farbenindustrie A.-G. Brit. 508,011, June 26, 1939. The layers are made by illuminating a photographic material comprising 1 or more Ag halide emulsion layers contg. dye components that are fast to diffusion (i. e., capable of conversion into dye by color degelopment or by azo-coupling and which, when added to the emulsion as a soln. or dispersion, cannot be removed or can only be removed with difficulty from a layer prepd. with the emulsion by any solvent or dispersion medium that normally dissolves or disperses the dye component) with colored or white light, if required, through a filter serving as a pattern, and producing a dye image by color development or by azo-coupling.

Light-sensitive photographic emulsions. Carl A. Schleussner. U. S. 2,181,383, Nov. 28. A photographic emulsion such as one contg. added glass beads or glass dust is treated with oscillations of approx. 100 meters wave length to produce a substantial increase in temp. of the emulsion and is artificially cooled during the treatment to maintain it at a substantially const. temp. of about 38°.

Stabilizing photographic emulsions. John D. Kendall. Brit. 508,073, June 22, 1939. Photographic material comprising a light-sensitive Ag halide emulsion and a support, i. e., a glass plate, film or paper therefor, is stabilized against changes during storage by the inclusion of a small quantity of a compd. of the formula

in which R^1 is a hydrocarbon or substituted hydrocarbon radical, e. g., an alkyl, aralkyl or aryl radical, an unsatd. aliphatic radical or a hydroxyphenyl radical, R^2 is H, a hydrocarbon radical, an NH_4 radical or a metal, e. g., an alkali metal, and A and B are similar or different and represent H or hydrocarbon radicals, which may be substituted, or together represent the remainder of a homocyclic ring with either H atoms or other univalent atoms or groups attached to the C atoms. Specified compds. are 2-thio-3-phenyl-, 2-thio-3,6-dimethyl-, 2-thio-3-ethyl-6-methyl-, 2-thio-3-allyl-6-methyl-, 2-thio-3-phenyl-6-methyl-, 2-thio-3,6-dimethyl-5-ethyl-, 2-thio-3-methyl-6-phenyl-, 2-thio-3,5,6-trimethyl-, 2-thio-3-ethyl-5,6-dimethyl-, 2-thio-3-allyl-5-ethyl-6-methyl-, 2-thio-3,5-diethyl-6-methyl-, 2-thio-5-benzyl-3,6-dimethyl- and 2-thio-5-benzyl-6-methyl-3-ethyl-4-ketotetrahydropyrimidines, 2-thio-3-methyl-, 2-thio-3-ethyl-, 2-thio-3-allyl-, 2-thio-3-phenyl-, 2-thio-3-(3′-hydroxyphenyl)-, 2-thio-1-methyl- and 2-thio-1-ethyl-4-ketotetrahydroquinazolines, Et 2-thio-4-keto-3-methyltetrahydropyrimidyl-3-acetate and 2-methylthio-4-keto-3,6-dimethyldihydropyrimidine.

Photographic developer. James R. Alburger (to Radio Corp. of America). U. S. 2,181,801, Dec. 5. A developer suitable for use with sound-track film may be formed, per l. of water, from Na_2SO_3 50, hydroquinone 15, Na_2CO_3 80, KBr 9, NaOH 30 and K alum 40 g.

Photographic developers. Paul Goldacker, Georg Maiser and Ernst Schmitz-Hillebrecht (to Agfa Ansco Corp.). U. S. 2,181,941, Dec. 5. Developing agents are used with an aliphatic hydroxyalkylamine contg. in its mol. at least one alkyl chain having at least 2 hydroxyl groups combined with different C atoms, such as methylglucamine, lactamine or mannamine, which serves as an alk. agent.

Color-forming photographic developers. Edmund B. Middleton and Andrew B. Jennings (to Du Pont Film Mfg. Corp.). U. S. 2,182,815, Dec. 12. An aromatic amino photographic developing agent is used with a dicyanoacetamidobisazole such as dicyanoacetamido-1,2,4,5-*p*-*β*-benzobisthiazole or the like.

Prismatic screen for additive photography. Gabriel G. Moreno (to C. M. C. Corp.). U. S. 2,182,993, Dec. 12. A method of producing a prismatic screen adapted for use in additive photography comprises: making a photographic record of an object composed of actinic and nonactinic parallel lines, the actinic lines having a width more than equal to but not materially exceeding twice the width of the nonactinic lines, developing the photographic record to form a graded image of all actinic lines, harden-

ing the gelatin of the photographic record and bleaching the record to remove the images and assocd. gelatin to form a prismatic relief consisting of a plurality of parallel spaced flat faces sepd. by V-shaped depressions having flat oppositely inclined opposing faces, the resulting screen being capable of transmitting more than 75% of light supplied thereto.

Tank and associated apparatus for liquid treatments of films. Albert W. Tondreau (to Warner Bros. Pictures, Inc.). U. S. 2,182,886, Dec. 12. Various structural and operative details for treating motion picture films after exposure. 2

Photographic film. Martin Marasco (to Du Pont Film Mfg. Corp.). U. S. 2,182,814, Dec. 12. A light-sensitive layer is joined to a support by means of an adhesive layer of a polymeric, amino-H-contg. substance such as piperidylmethylzein which is sol. in aq. HOAc of concns. of 2-5% but insol. in water and in 5% aq. NH_3 soln. This layer permits stripping after previous desired treatment. 3

[illegible] for printing. Max Herbst and Walter [illegible]ger (to Agfa Ansco Corp.). U. S. 2,181,485, Nov. 28. A process of producing a gelatin relief for printing comprises incorporating in a Ag halide gelatin emulsion a solid substance of which the main part has a particle diam. not exceeding 1 μ which substance does not affect the Ag halide and is insol. in the photographic treating baths, sensitizing the Ag halide emulsion for a spectral region different from its initial sensitivity, dyeing the Ag halide emulsion in a color complementary only to a part of the spectral region, casting the emulsion on a support to form a layer, producing a latent image in the layer, developing the image to a Ag picture, and etching the layer to form a relief.

Apparatus for making photographic prints. Kalle & Co. A.-G. Brit. 508,259, June 28, 1939.

Black and white photographic pictures. Johannes Kleine and Gustav Wilmanns (to Agfa Ansco Corp.). U. S. 2,181,944, Dec. 5. See Can. 382,711 (*C. A.* **34**, 8518[2]).

6—INORGANIC CHEMISTRY

W. C. FERNELIUS AND L. L. QUILL

The reduction of columbium pentoxide with hydrogen. Preliminary communication. G. Grube, O. Kubaschewski and K. Zwiauer. *Z. Elektrochem.* **45**, 885-8(1939).—On heating in argon, Cb_2O_5 is quant. changed to CbO_2, slowly at 1150° and much more rapidly at 1300°. Cb_2O_5 is reduced to CbO_2 by moist H_2; reduction of the dioxide to lower oxides is much more difficult. Reduction with dry H_2 gives the same product as with moist H_2 (p_{H_2O} = 1.44 mm. Hg), but is much more rapid. By varying working conditions the reduction products CbO_2, Cb_2O_3, CbO and Cb_2O can be obtained. The oxides are dark-gray to deep black; Cb_2O is gray with a slight metallic luster. Debye pictures show no elementary Cb in the four oxides. CbO_2, CbO and Cb_2O have independent lattices. Cb_2O_3 is a stoichiometric mixt. of CbO and CbO_2. M. McMahon 4

The lower oxidation steps of ruthenium in hydrochloric acid solution. G. Grube and H. Nann. *Z. Elektrochem.* **45**, 874-80(1939).—In the electrolytic reduction of $RuCl_3$ in coned. HCl solns. the bivalent stage occurs near the metal sepn., while in dil. HCl soln., the univalent stage occurs. These lower oxidation steps were identified and detd. by potentiometric titration with H_2O_2. In 2 *N* HCl soln. the bivalent Ru appears to be relatively stable, while the univalent Ru is rapidly changed according to $2Ru^+ \rightarrow Ru + Ru^{++}$. This change also occurs so rapidly in 0.1 *N* HCl soln. that a 0.01 *M* soln. was decomposed at room temp. in 24 hrs. In HCl solns. weaker than 2 *N*, bivalent Ru is not stable: $3Ru^{++} \rightarrow Ru + 2Ru^{+++}$. The potential of the reaction $Ru^+ - e^- \rightleftarrows Ru^{++}$ in 0.1 *N* HCl lies in the region E_H = +0.03 to 0.05 v. Accordingly, in HCl soln. univalent Ru is by no means a strong enough reducing agent to decompose H_2O, as was assumed by Manchot (*C. A.* **26**, 1534; **27**, 4493). In the HCl soln. it changes to the bivalent stage not by decompn. of H_2O, but with the sepn. of metallic Ru. M. McMahon 5 6

Combination of zinc nitrate with alkali metal nitrates. Robert Chauvenet. *Compt. rend.* **210**, 50-2(1940); cf. *C. A.* **33**, 1619[4].—Similar detns. of the surface tension of solns. (2*N* except $CsNO_3$, which was 0.607 *N*) of varying compn. indicate max. or min. deviations from the tension calcd. by the additivity law for solns. contg. the mixed salts as represented by the following formulas: ($Zn(NO_3)_2$ = I) 9I.7LiNO$_3$, I.LiNO$_3$, and 3I.5LiNO$_3$; 5I.3CsNO$_3$, I.CsNO$_3$, and 7I.9CsNO$_3$; 2I.NaNO$_3$, I.NaNO$_3$, I.2NaNO$_3$, and I.3NaNO$_3$. The only double salt indicated by this method or those previously described that has been obtained in the solid state is I.NaNO$_3$.5.5H$_2$O. C. A. S. 7

Constitution of thiocyanic acid. Fernand Gallais and Daniel Voigt. *Compt. rend.* **210**, 104-6(1940).—In aq. solns. contg. 59-193 g./l. of the acid, prepd. either by the method of Gluud, *et al.* (*C. A.* **20**, 2983), or by acting with H_2SO_4 on $Ba(NCS)_2$, the mol. magnetic rotations ($\times 10^3$) were detd. for $\lambda\lambda$ 5780, 5460 and 4360 as 177, 204 and 343, resp. This agrees with the values deduced from Gabiano's value for Et isothiocyanate (cf. *C. A.* **27**, 4972), and indicates that the acid is isothiocyanic. C. A. Silberrad 8

Quadrivalent molybdenum. III. Oxychloromolybdous acid. Stability of acid solutions of quadrivalent molybdenum. W. F. Jakób and L. Cyrus-Sobolewski. *Roczniki Chem.* **19**, 146-50(1939); cf. *C. A.* **27**, 5668.—$K_4[Mo(CN)_4(OH)_4]$ heated with dil. HCl yields $Mo(CN)_2(OH)_2$, which is boiled under reflux (3 hrs.) with coned. HCl. The soln. is coned. *in vacuo* to a sirup, which is extd. with Et_2O. This dissolves $H_2Mo^{V}OCl_5$, leaving H_2MoCl_5 in the aq. layer, from which a violet oil seps., yielding solid $MoCl_3(OH).3H_2O$ (I) when dried. Solns. of I are violet, yield a brown ppt. with aq. NH_3, and do not change color with CNS^- or MoO_4^{--}. **IV. Decomposition of octacyanomolybdous acid. Dicyanic acids.** *Ibid.* 151-5.—$K_4Mo(CN)_8$ boiled with 3% H_2SO_4 yields HCN and $Mo(CN)_2(OH)_2.xH_2O$, oxidized by H_2O_2 to $H_4Mo(CN)_8.3MoO_2.xH_2O$. B. C. P. A. 9

Complex chlorides of quadrivalent rhenium. B. Jeżowska-Trzebiatowska and Cz. Jodko. *Roczniki Chem.* **19**, 187-98(1939).—$HReO_4$ in 30% HCl and MI (24 hrs. at 20° in a CO_2 atm.) yield $M_4[Re_2OCl_{10}]$ (M = K, NH_4, quinoline), together with $M_2[ReCl_5OH]$ (M = K, NH_4, Rb, quinoline) and M_2ReCl_6. B. C. P. A. 10

Hydrate isomerism and hydrolysis of ruthenium trichloride. G. Grube and H. Nann. *Z. Elektrochem.* **45**, 871-4(1939).—On dissolving the salt $RuCl_3.H_2O$, obtained by concn. of a $RuCl_3$ soln. in a vacuum desiccator over coned. H_2SO_4, in ice-H_2O, the freshly prepd. brown to greenish brown soln. contains no ionized Cl. After a short time the color of the soln. changes to green. In the absolutely green soln. there is one ionized Cl for each Ru. Previously only the first two steps of the hydrate isomerism in Ru could be detected:

$$\left[\begin{matrix}Cl_3\\Ru\\H_2O\end{matrix}\right] + H_2O \rightarrow \left[\begin{matrix}Cl_2\\Ru\\(H_2O)_2\end{matrix}\right]Cl + H_2O \rightarrow$$

$$\left[\begin{matrix}Cl\\Ru\\(H_2O)_3\end{matrix}\right]Cl_2 + H_2O \rightarrow [Ru(H_2O)_4]Cl_3$$

If the green soln. of the salt $\left[\begin{matrix}Cl_2\\Ru\\(H_2O)_2\end{matrix}\right]Cl$ is heated, the color changes to brown and sol. hydrolysis products are formed, with sepn. of free HCl. M. McMahon

Nitrosyl compounds of platinum. A. D. Hel'man and

Z. P. Maksimova. *Compt. rend. acad. sci. U. R. S. S.* **24**, 748–51(1939)(in English).—On allowing a satd. soln. of K or NH_4 chloroplatinite to stand 3–4 days in a NO atm., a green soln. (I) formed, apparently contg. the ion $PtNOCl_5^-$. Addn. of $[Pt.4NH_3]Cl_2$ soln. to I gave a reddish gray ppt. of $[Pt.4NH_3][PtNOCl_5]_2$. Adding pyridine to I gave an immediate ppt. of $PtNOpyCl_2$ (II) (green). Dissolved in pyridine, II gave a yellow ppt. of $Ptpy_2Cl_2$ which reacted with thiourea to give *trans*-$Ptpy_2th_2$. Hence II has a trans configuration. N_2O does not react with chloroplatinite. A. O. Allen

Studies on the catalytic oxido-reduction by some metallic complex salts. XIV. Catalytic reduction by rhodium complex salts. Masaakira Iguti. *J. Chem. Soc. Japan* **60**, 1787–92(1939); cf. *C. A.* **34**, 1582[3].—Unstable rhodium complex salts such as $[Rh(NH_3)_5H_2O]Cl_3$ and $[Rh(NH_3)_4Cl_2]Cl$ accelerate the reduction of quinone by H_2, but stable complex salts such as $[Rh(NH_3)_6]Cl_3$, $[Rh(en)_3]Cl_3$ have no catalytic action. Rhodium chloride acts as a strong catalyst in the reduction of quinone, fumaric acid, methylene blue, sodium nitrite and hydroxylamine. T. Katsurai

Contribution to the constitution of heteropolyacids. II. A new class of ammines. The phosphododecatungstate complexes. G. Spacu and V. Nicolaescu. *Bull. sect. sci. acad. roumaine* **22**, 130–41(1939).—Detailed description of method of prepn. and analysis of $[Co\ en_2(NO_2)_2]_3H_4[P(W_2O_7)_6].8H_2O$, $[Co(NH_3)_4(NO_2)_2]_3H_4[P(W_2O_7)_6].7H_2O$, $[Cr(NH_3)_5Cl]_2H_3[P(W_2O_7)_6].17H_2O$, $[Co(NH_3)_5NO_2]_2H_3[P(W_2O_7)_6].11H_2O$, $[Coen_2Cl_2]_6H[P(W_2O_7)_6].15H_2O$ (*trans*), $[Cr(NH_3)_5SCN]_3H[P(W_2O_7)_6].14H_2O$, $[Coen_3]_2H[P(W_2O_7)_6].16H_2O$, $[Cren_3]_2H[P(W_2O_7)_6].19H_2O$, $[Cren_3]_2HN:C(NH_2)_2.H[P(W_2O_7)_6].19H_2O$. A. A. Vernon

7—ANALYTICAL CHEMISTRY

W. T. HALL

The fundamental reactions in analytical chemistry. V. Reactions of sodium vanadate with metallic ions. Yosinaga Oka. *J. Chem. Soc. Japan* **60**, 1279–86(1939); cf. *C. A.* **33**, 3286[9]. T. Katsurai

New reactions in qualitative analysis. Einar Jensen. *Tids. Kjemi Bergvesen* **19**, 57–60, 75–7(1939).—A review. H. Kringstad

Application of spectral analysis in mineralogy, geochemistry and metallurgy. V. M. Goldschmidt. *Tids. Kjemi Bergvesen* **19**, 82–6(1939).—A review on the quant. spectrographic methods and of the work carried out by G. H. Kringstad

The origin of iodometry. Anon. *Ann. chim. anal. chim. appl.* **22**, 203(1940). Alphonse Dupasquier (*Ann. chim. phys.* (2), **73**, 310(1840)) in recommending the detn. of the H_2S content of mineral waters by titrating with I_2 soln. to a starch end point appears to be the originator of iodometric methods. Fordos (*Compt. rend.* **16**, 1065 (1843)) discovered $Na_2S_4O_6$ and showed that it was formed by the action of $Na_2S_2O_3$ and I_2. This is the basic reaction of iodometry. Bunsen (*Annalen* **86**, 129(1853)) pointed out the general applicability of iodometry and the same year Schwartz, a German pupil of Pelouze, proposed the substitution of H_2SO_3 for $Na_2S_2O_3$. W. T. H.

Use of the limit of perceptibility in a qualitative test for determining the approximate quantity of some constituent. G. Gutzeit. *Helv. Chim. Acta* **23**, 17–24(1940). The sensitivity of a chem. test can be used to advantage in detg. the approx. quantity of a constituent. Two interesting examples of this are described. In one case, certain samples of solder proved unsatisfactory as a result of the presence of about 0.2% S. It was easy to det. whether enough S was present to do harm by making a S-print with sensitized paper impregnated with a soln. of $SbCl_3$ and just enough HCl to prevent hydrolysis. From a polished section pressed against the paper, a red spot of Sb_2S_3 developed when too much S was present. Of various reagents that react with solns. contg. Au, the sensitivity increases in the following order: $(NH_4)_2S$, H_3PO_2, H_2S, HCO_2H, $HgNO_3$, $FeSO_4$, H_2O_2 + KOH, *p*-dimethylaminobenzylidinerhodamine. Au can be detd. quickly in a mineral by dilg. the sample until the test with the last-named reagent is barely perceptible. It will detect as little as 0.02 γ of Au. W. T. H.

Possible source of error in gravimetric determinations involving the use of hydrogen peroxide followed by nitron. Ralph C. Young and Peter M. Bernays. *Ind. Eng. Chem., Anal. Ed.* **12**, 90(1940).—In the standard method for detg. Re the sulfide is oxidized with 30% H_2O_2 to perrhenic acid which is later pptd. with nitron. Trouble was encountered caused by the presence of a little nitrate in the concd. H_2O_2 from 3 well-known firms. W. T. H.

Analysis in gammas. M. Zürcher. *Mitt. Lebensm. Hyg.* **30**, 190–200(1939).—A review of the development of microanalytical techniques illustrating the practicability of various types of analysis with an accuracy of 1 γ. W. J. Peterson

Use of organic reagents in the scheme of general [qualitative] analysis. Elio A. Moreira. *Rev. brasil. chim.* (São Paulo) **8**, 251–5(1939).—Known methods are discussed. L. E. Gilson

The availability of some oxine derivatives in analytical chemistry. Jacob Molland. *Tids. Kjemi Bergvesen* **19**, 119–22(1939).—8-Hydroxyquinoline-5-sulfonic acid and halogen derivs. of this acid (in the 7-position) have proved to be valuable in colorimetric detn. of Fe and metavanadates. 7-Nitrous-8-hydroxyquinoline-5-sulfonic acid is a suitable pptg. agent for Pb and can also be used for some alkaloids. H. Kringstad

Indicators. G. Schwarzenbach. *Mitt. Lebensm. Hyg* **30**, 148–64(1939).—Application of the Brönsted acid base concept in analytical problems has presented many new possibilities in the study of indicators. For example, the orthodox pH range from 0 to +14 may now be changed conveniently to include the range from −10 to +16. Anilinesulfonephthalein dyes are discussed in these terms. W. J. Peterson

Adsorption by ionic precipitates and adsorption indicators. James J. Lingane. *Pacific Chem. Met. Inds.* **4**, No. 1, 17–20(1940).—A review with 17 references. W. T. H.

Bromocresol green-methyl orange as alkalinity indicator. F. M. Hull. *Public Works* **70**, No. 4, 34(1939).—The combination of bromocresol green and methyl orange for routine detn. of total alky. is much better than methyl orange alone. The alk. soln. is blue and the acid, yellow. The prepn. of the indicator is given. George Papps

Estimation of small amounts of arsenic in copper. Bartholow Park. *Ind. Eng. Chem., Anal. Ed.* **12**, 97–8 (1940).—Dissolve 10 g. of metal in a mixt. of 20 ml. concd. H_2SO_4, 20 ml. concd. HNO_3 and water to make 100 ml. Boil off brown fumes, add 10 g. of tartaric acid which has been dissolved in a little water, dil. to 350 ml. and electrolyze until practically all Cu is deposited. Remove and wash the electrodes. Neutralize the electrolyte with NH_4OH and add 3.4 ml. of 6 *N* HCl for each 100 ml. of soln. Sat. with H_2S to ppt. the As. Dissolve the sulfide ppt. in boiling hot HNO_3 and det. the As spectrographically or by any other desired method. The results were checked by adding 0.25 mg. of As to 50 g. of Cu which was free from As. 17 references. W. T. H.

Colorimetric determination of arsenic in ferrous and nonferrous alloys. Clement J. Rodden. *J. Research Natl. Bur. Standards* **24**, 7–11(1940)(Research Paper No. 1267).—Dissolve 0.1-g. sample in 7.5 ml. of 7.5 *N* HNO_3, evap. to dryness, cool, add 5 ml. of concd. HCl and transfer to a distg. flask with 10.0 ml. more of this acid. Add 2 ml. of HBr and 0.3 g. of hydrazine sulfate dissolved in 10 ml. of concd. HCl. Distil in a stream of CO_2 and

catch the distillate contg. $AsCl_3$ in a little water. To the distillate add 10 ml. of concd. HNO_3 and evap. to dryness to oxidize the As to H_3AsO_4. Heat the residue at 130° for an hr. Take 10 ml. of soln. prepd. from 1 g. NH_4 molybdate, 100 ml. 5 *N* H_2SO_4, mix with 1 ml. of 0.15% hydrazine sulfate soln. and add the mixt. to the H_3AsO_4 soln. Use 10 ml. of the reagent for each 30 mg. of As. Cool and to the cold soln. add more molybdate soln. to make the concn. not over 3 γ per ml. Measure the light transmission of the blue soln. in a photoelec. colorimeter with the reagent in the comparison cell. W. T. H.

Determination of small quantities of beryllium in magnesium alloys by a spectrographic method. A. Beerwald. *Z. Elektrochem.* **45**, 833–5(1940).—The method chosen is based on the work of Scheibe and Rivas (*C. A.* **30**, 6302[7]). Solns. to be analyzed are evapd. upon spectrally pure carbon and made to cause light emission by means of elec. sparks. Very good results were obtained by comparison of the Be doublet at 3131.06 A. and 3130.42 A. The former is the stronger line and can be compared with the Al line at 3050.07 A. W. T. H.

Microchemical determination of cadmium with anthranilic acid. P. Wenger and E. Masset. *Helv. Chim. Acta* **23**, 34–8(1940).—To a soln. contg. 1–3 mg. of Cd at pH 6, and contg. no HCl or AcOH add, at the b. p., 0.55 ml. of a freshly prepd. 2% soln. of Na anthranilate. Stir, allow to cool completely, filter, wash twice with 1 cc. of 96% EtOH, dry at 135–140° and weigh. Good results were obtained with 3 types of microchem. filters. Cf. *C. A.* **29**, 6169[2]. W. T. H.

Volumetric determination of bismuth and of the acidity of solutions of bismuth salts. L. Malaprade. *Ann. chim. anal. chim. appl.* **22**, 5–8(1940).—It is difficult to neutralize free acid in a soln. of Bi^{+++} salt because during the neutralization fresh H^+ is formed by hydrolysis. If, however, a $Bi(NO_3)_3$ soln. contg. only a little excess HNO_3 is treated with excess $Na_2S_2O_3$, the Bi^{+++} ions are converted into $Bi(S_2O_3)_3^{---}$ anions which are not hydrolyzable. Free HNO_3 can then be neutralized by titrating with KOH to a methyl red end point. Too much HNO_3 should not be present at the start or there is likely to be decompn. of the thiosulfate and pptn. of some Bi_2S_3. If now the neutralized soln. contg. KNO_3 is titrated with KOH to a phenolphthalein end point, the following reaction takes place; $2Bi(S_2O_3)_3^{---} + 5OH^- + NO_3^- \rightarrow BiO.NO_3BiO_2H + 6S_2O_3^{--} + 2H_2O$ and this titration will serve for the detn. of the Bi. To apply this method of analysis to a solid subnitrate, oxide or sulfide, dissolve the sample in as little HNO_3 as possible, add a few drops of methyl red indicator soln. and titrate with KOH until the indicator begins to show a yellow color. Now add about 10 g. of $Na_2S_2O_3$ crystals and add dil. HNO_3 very carefully until the ppt. of Bi salt dissolves. When the ppt. shows a very slow rate of dissolving, add a few drops of the acid at a time and wait for some time before adding fresh acid and in this way use very little excess acid after a permanent pink color of the methyl red is reached. Then titrate back carefully with KOH soln. Now add 10 drops of phenolphthalein indicator soln. and titrate slowly and carefully, particularly toward the last. The results obtained with a sample of 0.365 g. of Bi_2O_3 were within 0.5% of the truth. W. T. H.

A new method of separation and determination of gold in sea water. Masayosi Isibasi and Mutuaki Sinagawa. *J. Chem. Soc. Japan* **60**, 1265–8(1939).—The sea water is evapd. until reduced to about 6% of the original vol. Formalin is added as the reducing agent and the sea water is subjected to dialysis. Colloidal Au remains with a certain amt. of insol. salts. The Au is then collected by means of cupellation. T. Katsurai

Sources of error in the volumetric determination of iron by the Kessler-Reinhardt method. H. Blumenthal. *Wiss. Abhandl. deut. Materialprüfungsanstalt* **1939**, No. 3, 75–9.—The titration of Fe^{++} by MnO_4^- in HCl solns. gives accurate stoichiometric results when not more than 10 ml. of HCl and sufficient $MnSO_4 + H_3PO_4$ are present in a final vol. of at least 500 ml. If, however, more than 1% of Cu is present in the sample analyzed, the results will be low. The error is caused by the fact that dissolved O_2 in the presence of Cu^{++} has an oxidizing effect upon Fe^{++}. W. T. H.

Basis of the colorimetric determination of magnesium by means of "titan yellow." H. Ginsberg. *Z. Elektrochem.* **45**, 829–33(1940).—Titan yellow is the Na salt of dihydrothio-*p*-toluidinesulfonic acid. If $Mg(OH)_2$ is formed by the addn. of NaOH to a soln. contg. the dye, the surface of the ppt. in alk. soln. is colored a dark red. In the colorimetric test for Mg a state of equil. exists between the dyestuff and the so-called color lake. The value of this equil. was detd. at various concns. so that a suitable curve could be drawn for the interpretation of the results. The points on the curve do not correspond to the formation of a definite lake and the intensity of the color does not increase indefinitely but reaches a max. The lake formation, therefore, follows the simple laws of adsorption. Math. analysis shows the justification of the colorimetric comparison in the presence of both lake and dyestuff but the latter should always be present in excess. W. T. H.

Detection of mercury by formation of a ring of mercuric iodide. R. Cambar. *Bull. trav. soc. pharm. Bordeaux* **77**, 207–15(1939).—The Hg is plated on a Cu strip from which it is removed, after drying, by gentle heat in a dry tube in which a particle of I has been sublimed into a drawn-out and cooled portion of the tube. The ring of HgI_2 is formed by direct reaction in the narrow part of the tube. S. W. Goldstein

The analytical chemistry and microchemistry of thallium. Georges Denigès. *Bull. trav. soc. pharm. Bordeaux* **77**, 193–202(1939).—Properties similar to those of Pb are utilized in analyses for Tl. Det. the Tl in a sample by a colorimetric and nephelometric procedure with KI reagent. Dil. the weighed sample with 10 times its wt. of water, and filter. To an aliquot add 2 drops per cc. of sirupy gum arabic soln., and 1 drop per cc. of 10% KI soln. Compare with a control using $Tl_2(SO_4)_3$ soln. Results are best when the sample contains between 0.005 and 0.10 g. Tl per l. Microcryst. ppts. obtained with 10% HIO_3, 5% Na benzoate and picric acid (satd. soln.) are described. S. W. Goldstein

Determination of traces of metavanadates. Jacob Molland. *Compt. rend.* **210**, 144–6(1940).—A soln. of a metavanadate added to one of 8-hydroxyquinoline-5-sulfonic acid gives a permanent brown color which can be used to est. V colorimetrically with an error of 2.05% in a soln. contg. 5×10^{-5} g. mol./l. of NH_4VO_3, or 2.55 mg./l. V, and a smaller error in stronger solns. The coeff. of extinction $k = (1/e) \log_{10} (I_0/I)$ is proportional to the concn. of metavanadate if the ratio $[NH_4VO_3]/[C_9H_6N(OH)(HSO_3)]$ is less than 0.375. C. A. Silberrad

Determination of zinc as zinc mercuric thiocyanate. Imre Sarudi (nee Stetina). *Österr. Chem.-Ztg.* **42**, 297–8(1939).—To a soln. contg. about 0.1 g. Zn and 1–2 milliequiv. of HNO_3 add 40 ml. of a reagent prepd. with 27 g. $HgCl_2$ and 39 g. KCNS per l. After 30 min. filter and wash successively with water, EtOH and Et_2O and weigh. The sensitivity is increased by adding to the soln. contg. the ppt. about one-third as much 96% EtOH and by washing with 33% EtOH instead of water. W. T. H.

Chlorine. Anon. *Dept. Sci. Ind. Research* (Brit.), *Methods for the Detection of Toxic Gases in Industry, Leaflet* No. 10, 7 pp.(1939).—The test recommended consists in drawing samples of air through a bubbler contg. *o*-tolidine soln. until the depth of color produced is equal to that of a series of standards prepd. from $K_2Cr_2O_7$. W. T. H.

Rapid determination of carbon and silicon in cast iron. F. Roll. *Giesserei* **27**, 9–11(1940).—A practical method for detg. the probable Si + C content of a sample of cast Fe before the molten alloy is poured consists in examg. the fracture of a wedge-shaped piece of metal. Full details are given for prepg. the small casting and the appearance of the fracture is shown by 10 illustrations of cast Fe contg. 2.7% C and 1.17% Si to 3.46% C and 2.09% Si. This practical test has little use when the main mass of metal has already been poured from a cupola furnace. The time estd. as necessary for detg. C by burning and

measuring the vol. of CO_2 is about 9 min. and for detg. the Si about 28 min. according to current German practice. The wedge test can be finished in about 2.5 min. from the time the sample of molten metal is ladled out. W. T. H.

Arsine. Anon. *Dept. Sci. Ind. Research* (Brit.), *Methods for the Detection of Toxic gases in Industry, Leaflet* No. 9, 6 pp.(1939).—The method consists in drawing the air through paper which has been impregnated with $HgCl_2$ soln. and comparing the color of the stain, if any, with that obtained with known quantities of AsH_3. W. T. H.

Phosgene. Anon. *Dept. Sci. Ind. Research* (Brit.), *Methods for the Detection of Toxic Gases in Industry, Leaflet* No. 8, 7 pp.(1939).—The only simple method now known for detecting small quantities of $COCl_2$ in the atm. is by the use of a test paper contg. diphenylamine and *p*-dimethylaminobenzaldehyde. The yellow or orange stain will detect as little as 4 γ per l. It has been made quant. by drawing a known vol. of air with a hand pump of specified capacity through the test paper and comparing the stain with a reference color chart. W. T. H.

Precipitation of barium sulfate in the presence of ammonium chloride. J. T. McHenry, G. A. Ampt and E. Heymann. *J. Am. Chem. Soc.* **62**, 448–9(1940).—In the pptn. of $BaSO_4$ in the presence of NH_4Cl a linear relation exists between the log of the amt. sorbed and the NH_4Cl concn. $BaSO_4$ ppt. in the presence of *N* NH_4Cl contains 7 mg. of NH_3 (as $(NH_4)_2SO_4$) per 1 g. of $BaSO_4$; in the ppt. about 50% of the NH_3 is present as $(NH_4)_2SO_4$. On boiling with 0.02–0.01 *N* NaOH, NH_3 distils over very slowly, 10–15 hrs. being required to expel most of it. This can be explained on the assumption that the contaminating salt is mainly present inside of the macrocrystal. C. J. West

Analysis of mixtures containing monopotassium and monoammonium phosphates. D. I. Kuznetsov and A. A. Kozhukovskiĭ. *Compt. rend. acad. sci. U. R. S. S.* **24**, 752–4(1939)(in English).—The NH_3 is expelled by evapg. to dryness 3 times with aqua regia before pptn. of the $KClO_4$. The P_2O_5 was weighed as $MgNH_4PO_4.6H_2O$ and the results were as accurate as when converted into $Mg_2P_2O_7$. A. O. Allen

Method for the determination of carbonate in small amounts of materials. F. E. Jones. *J. Soc. Chem. Ind.* **59**, 21–3(1940).—The method is a modification of the vacuum type method which has been used since 1924 in Australia for the examn. of baking powder. Similar methods have been described by Edwards, Parkes and Nanji (*C. A.* **30**, 1875[8]) and by Cornell (*C. A.* **31**, 1644[4]). Two 4-in. test tubes are connected by means of side arms which are blown into the glass. The sample is decompd. in one of them by means of 2.5 *N* HCl which is added from a dropping funnel attached to the top of the tube. Then suction is applied to the system and the CO_2 is absorbed in a measured vol. of standard $Ba(OH)_2$ soln. The excess of the base is titrated with acid to a phenolphthalein end point. W. T. H.

Analysis of sulfite solutions containing selenium. A volumetric method. R. C. Shaver and C. R. McCrosky. *Ind. Eng. Chem., Anal. Ed.* **12**, 74–6(1940).—$KBrO_3$ will oxidize H_2SO_3 completely before it reacts with red Se in the colloidal state, provided proper conditions are maintained. To 25 ml. of soln. contg. K_2SO_3 + Se + starch soln. add all but about 1 ml. of the necessary quantity of 0.1 *N* $KBrO_3$ as detd. by a preliminary titration. Stir mechanically and add all at once 70 ml. of 6 *N* HCl. After the electron-beam sectrometer which has been set by the preliminary titration shows a closed shadow again, titrate dropwise until the sectrometer shadow remains open for at least 1 min. This titration shows the BrO_3^- required to oxidize SO_3^{--} to SO_4^{--} and the Se to H_2SeO_3. After this oxidize the H_2SeO_3 to H_2SeO_4 by the method of Norris and Fay (*Am. Chem. J.* **18**, 704(1896)). The starch is added before acidification in order to stabilize the red Se formed and serves as indicator in the final titration. W. T. H.

Stability of peroxidized titanium solutions. Gilbert H. Ayres and Edmay M. Vienneau. *Ind. Eng. Chem., Anal. Ed.* **12**, 96(1940).—The color produced by H_2O_2 in solns. contg. 4–80 mg. Ti per l. proved stable over a period of 2 yrs. The readings agreed in most cases at 15 different concns. within the limits of accuracy of the colorimeter used. W. T. H.

Differentiation of inks and their chloride and sulfate migrations. John Finn and Robert E. Cornish. *News Ed. (Am. Chem. Soc.)* **18**, 174(1940).—Some practical applications of the method of detg. the age of ink (cf. *C. A.* **32**, 7851[8]) are described. Thus in a court case it was shown that the entries on a physician's record could not possibly have been made at one time. W. T. H.

Pharmaceutical part in passive defense. Chemical detection. Louis Maricq. *J. pharm. Belg.* **21**, 749–55(1939).—A discussion of the procedures and app. required for detection and identification of toxic gases. S. W. Goldstein

Extraction of strychnine in toxicology. E. Kergonou. *Bull. trav. soc. pharm. Bordeaux* **77**, 203–6(1939).—Results obtained by electrodialysis and extn. by the Stass-Otto method are compared. The former recovers a greater part of the alkaloid (94–100%), but the following modification of the S.-O. procedure gives yields of 37–55% and will detect about 2 mg. per kg. Dissolve the residue obtained by the S.-O. method in a little distd. water acidified with HCl, ppt. the strychnine with Mayer's reagent satd. with HgI_2, recover the ppt. by centrifuging, suspend it in distd. water and remove the Hg with H_2S. Evap. the soln. on a water bath, alkalinize and ext. the strychnine with $CHCl_3$. S. W. Goldstein

Determination of small amounts of copper and manganese in dyes and other organic materials. G. F. Palfrey, R. H. Hobert, A. F. Benning and I. W. Dobratz. *Ind. Eng. Chem., Anal. Ed.* **12**, 94–6(1940).—Methods for detg. small quantities of Cu and Mn in *dyes, intermediates, rubber chemicals* and *rubber* which may contain Fe, Pb, Zn, Ba, Al and small quantities of Cd are described. The methods give results which are accurate to within 5% of the small quantity of Cu or Mn which is actually present. The org. matter is destroyed by suitable treatment with H_2SO_4, HNO_3 and H_2O_2. The Cu is detd. colorimetrically by means of diethyldithiocarbamate with suitable modifications when Pb or Zn is present. The Mn is detd. colorimetrically after oxidation to MnO_4^{II} by KIO_4. W. T. H.

Analysis of the products of the sulfonation of fatty alcohols. E. Schmidt. *Teintex* **4**, 650–3(1939).—Hydrolysis of a H_2SO_4 ester of a satd. fatty alc. regenerates the pure alc. Hydrolysis of any unsatd. fatty alcs. that have been treated with H_2SO_4 will yield a mixt. of pure alc. and glycol because of addn. to the double bond. On these reactions is based a means of analyzing sulfonated products. The sample is boiled with an acid and the mixt. extd. with ether or ligroin. The ext. is filtered and evapd. to const. wt. Instead of the —C.OSO$_3$H group, some com. products contain the —C.SO$_3$H group which is not split with dil. HCl. Its products dissolve in the acid or form an intermediate layer between the ether and the acid, resulting in a yellow coloration of the acid layer. These products can easily be isolated. If a mixt. of sulfonated alcs. does not contain the —C.SO$_3$H group the following procedure is used: To 25 cc. of warm distd. H_2O add 5–7 g. of the sample. After adding 50 cc. of 6 *N* HCl, reflux the mixt. for 1 hr. and then ext. with 2 portions of ligroin to dissolve the alcs. Wash the ext. with H_2O and filter over anhyd. Na_2SO_4. If the —C.SO$_3$H group is present in the original sample, it is necessary to modify the procedure, as it is sol. in the ether ext. In this case wash the ether ext. with 70 vols. of warm EtOH contg. some NaOH, and reflux 30 min. on a water bath. This step removes any substances contg. the —C.SO$_3$H group from the ligroin ext. or the ether ext. Saverio Zuffanti

Determination of formaldehyde in protein solutions. (A note on a new micromethod). J. O. Alcock and J. S. Otto. *S. African J. Med. Sci.* **4**, No. 1–2, 31–5(1939).—A modification of the method of Oyama (*C. A.* **30**, 5150[2]) is described. When the ppt. formed by trypaflavine and

CH_2O is redissolved and treated with dil. HNO_2, there is formed a highly colored "nitrated" compd. suitable for colorimetric comparison with a standard. The test is remarkably sensitive and suitable for general purposes. The color is sufficiently stable and proportional to the concn. of CH_2O taken. Two graphs and 2 tables are given.
W. R. Henn

Hydroxamic acids in qualitative organic analysis. David Davidson. *J. Chem. Education* **17**, 81–4(1940).— Hydroxamic acids can be regarded as the *n*-hydroxy derivs. of the acid amides or as the oximes of the carboxylic acids. In either case, they can also be represented by amine oxide formulas. These tautomeric substances can be prepd. in so many ways and they are so easily detected that the possibility of using them in org. qual. analysis is clear. Thus an *ester* can be identified as follows: To 1 drop of the sample, add 0.5 ml. of *N* $NH_2OH.HCl$ in MeOH and 0.5 ml. of 2 *N* KOH in MeOH. KCl will ppt. from the MeOH soln. Heat to boiling, cool, make acid with 0.5 ml. of 2 *N* aq. HCl and test with a drop of 10% $FeCl_3$ aq. soln. A red color will develop. An *alc.* can be detected by taking 0.5 ml. AcCl and an equal vol. of dimethylaniline and then 0.5 ml. or 0.5 g. of the sample. The mixt. will sep. into 2 layers. Add ice to decompose excess AcCl and treat 1 drop of the oily ester layer with hydroxylamine, etc., as in the case of esters. *Ethers* give neg. tests by the above procedures but they can be converted into esters by heating with org. acids in the presence of a little concd. H_2SO_4. The ester formed can be detected as above. *Carboxylic acids* can be treated with $SOCl_2$ and when the excess has been removed by evapn. the resulting acyl chloride can be tested as in the case of esters. *Phenols* can be changed to esters by treatment with AcCl. *Nitro compds.* can be reduced to an alkylhydroxylamine which gives BzCl a *n*-alkylhydroxamic acid and this yields a colored complex with $FeCl_3$. *Aliphatic amides* are converted rapidly to hydroxamic acids by boiling with $NH_2OH.HCl$ soln. *Cyanates* by treatment with $NH_2OH.HCl$ can be converted to hydroxamic acids which give a purplish blue complex with $FeCl_3$. 36 references

Preparation of semicarbazones by functional exchange. Bernard Angla. *Ann. chim. anal. chim. appl.* **22**, 10–15 (1940).—In org. analysis the carbonyl group is often characterized by the formation of a carbazone. The usual method consists in treating with semicarbazide-HCl in the presence of alkali acetate. Sometimes pyridine is used instead of alkali acetate and in other cases the free semicarbazide is employed. It has been found that the semicarbazone can also be formed by the action of semicarbazide-HCl upon the bisulfite compds. of aldehydes or ketones or even upon oximes. The method consists in causing the carbonyl compd. to react with the semicarbazone of a volatile aldehyde or ketone. The semicarbazone of acetone appears to be most suitable; it is easily prepd. pure and there is less danger of side reaction taking place than when a substance like the semicarbazone of HCHO is used. In most cases the formation of the new semicarbazone takes place in the presence of AcOH and it is necessary to make sure that all the acetone formed is eliminated. In some cases it is better to work in a neutral soln. CO_2 gas is often effective in removing acetone and in providing the necessary acidty. W. T. H.

Aniline vapor. Anon. *Dept. Sci. Ind. Research* (Brit.), *Methods for the Detection of Toxic Gases in Industry, Leaflet* No. **11**, 9 pp.(1939).—To detect aniline vapor in the atm. a sample of air is passed through a small bubbler contg. dil. HCl. This yields a soln. of aniline chloride which, if the concn. of aniline is considerable, gives with bleaching powder a purple coloration, rapidly changing to a dirty red. The concns. of aniline in air likely to be encountered give only a trace of color. The test can be made more sensitive by making the soln. slightly ammoniacal after the bleaching powder is added and then adding a little phenol soln.; a permanent deep-blue color is produced even with 1 part of aniline in 100,000 parts of air. W. T. H.

Analysis of aniline-water solutions. John Griswold. *Ind. Eng. Chem., Anal. Ed.* **12**, 89–90(1940).—A rapid procedure for titrating aniline with 0.02 *N* Br_2 soln. or with 1.5 *N* $KBrO_3$-KBr soln. and with potentiometric detn. of the end point is described. For detg. water in aniline, the method of mixing with rapeseed oil and observing the first indication of clouding proved satisfactory. These methods are not new, but the procedure here described is rapid. W. T. H.

Analysis of naphthenic acids. J. R. M. Klotz and Edwin R. Littmann. *Ind. Eng. Chem., Anal. Ed.* **12**, 76–7(1940).—Com. naphthenic acids are complex mixts., some of which contain acids which are appreciably volatile during evapn. of petroleum ether. If the unsaponifiable matter has been removed by preliminary extn. this loss can be allowed for in the final titration. Take 2–3 g. of the naphthenic acid, dissolve in 25 ml. of EtOH and titrate with 0.5 *N* NaOH to a phenolphthalein end point. Dil. with 25 ml. of water and shake with two sep. 15-ml. portions in a separatory funnel. Return the aq. layer to the funnel, after clearing it with EtOH, add 15. ml. of 10% H_2SO_4 and again shake with 25 ml. of petroleum ether. Discard the lower aq. layer and filter the combined petroleum ether soln. through dry paper into a weighed Erlenmeyer flask. Rinse the funnel with 10 ml. of the petroleum ether. Evap. to dryness and heat 2 hrs. at 110–115°. After a const. wt. has been obtained by drying, dissolve the acids in 25 ml. of EtOH and again titrate with NaOH. W. T. H.

Determination of total creatinine, especially small quantities. Th. von Fellenberg. *Mitt. Lebensm. Hyg.* **30**, 220–39(1939).—Yeast ext. (4 g.) is brought to 100 cc. with H_2O and 5 cc. of the soln. (0.2 g. ext.) is evapd. with 10 cc. concd. HCl in a deep porcelain dish. The residue is taken up with H_2O and then poured through an 8-mm. (diam.) column contg. a layer of 3 g. of Al_2O_3. Five cc. of the clear filtrate (0.1 g. ext.) is treated with 1 drop HCl and evapd. to dryness over a water bath. The residue is treated with 1.5 cc. of 1.2% picric acid and 1 cc. of 10% NaOH. After 5 min. the soln. is dild. to 50 cc. and compared with 0.5 *N* dichromate soln. The no. of mg. of creatinine in 50 cc. of the reaction soln. = $[(h + 2.3)/h_1] \times 0.787$ where h = height in mm. of 0.5 *N* dichromate soln., h_1 = mm. of the creatinine reaction product. Accurate values of from 0.2 mg. to 1.0 mg. per 50 cc. of final soln. can be detd. W. J. Peterson

Microdetermination of homocystine in pure solution with the dropping-mercury cathode. Adolph Stern and Eliot F. Beach. *Proc. Soc. Exptl. Biol. Med.* **43**, 104–8 (1940); cf. *C. A.* **33**, 9346⁴.—Homocystine and homocysteine can be detd. polarographically after addn. of NH_4OH, NH_4Cl and $CoCl_2$. In solns. contg. 26 γ per cc. the accuracy is ±3%. The quantity of sulfhydryl in mixts. of homocystine and cystine can be detd. with the same accuracy but it is not possible to distinguish homocystine from cystine qualitatively by this method.
L. E. Gilson

Electrometric method for the determination of mercaptobenzothiazole. Petru G. Spacu. *Bull. sect. sci. acad. roumaine* **22**, 142–5(1939).—Mercaptobenzothiazole can be analyzed electrometrically by measuring the voltage of a cell composed of a AgCl electrode, 80% acetone soln. of mercaptobenzothiazole, normal calomel electrode. 0.05 *N* $AgNO_3$ is used as the titrating agent. The inflection point was at +0.197 v., and the error of analysis about −0.5%. A. A. Vernon

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

ARTHUR M. BRANT

Heat of diffusion of helium as a criterion of the utility of minerals for the determination of age by the helium method. E. K. Gerling. *Compt. rend. acad. sci. U. R. S. S.* **24**, 570–3(1939)(in German).—A value of 34,000 cal./g. atom, calcd. for the heat of diffusion of He in a 2
mineral, guarantees the complete preservation of the original quantity of He in the mineral and indicates that the mineral lattice is free from appreciable derangement. The method of calcn. of the heat of diffusion from exptl. data is described and values of the heat of diffusion of He for 5 minerals are listed. George Ayers

Hardness of gem zircon. Karl Chudoba. *Deut. Goldschmiede-Ztg.* **41**, No. 1, 10–11(1938); *Neues Jahrb. Mineral. Geol.*, Ref. I, **1938**, 427.—The hardness of zircon 3
varies with its density, zircons of d. 4.68 and 3.92 having hardnesses of 490 and 320, resp., while one of intermediate d. had H = 420. C. A. Silberrad

Crystal structure of nocerite. Antonio Scherillo. *Periodico mineral.* (Rome) **9**, 229–48(1938); *Mineralog. Abstracts* **7**, 233(1939).—The unit cell of nocerite has *a* 8.84, *c* 3.12 A., and contains 3 mols. $Ca_3Mg_3O_2F_8$, space group C_h^1 or C_{2h}^1. C. A. Silberrad

X-ray determinative tables for minerals. I. A. K. 4
Boldyrev, V. I. Mikheev, G. A. Kovalev and V. N. Dubinina. *Ann. inst. mines* (Leningrad) **11**, Pt. 2, 1–157 (1938); *Mineralog. Abstracts* **7**, 226–7(1939).—Values of *d*/*n* of lines in x-ray patterns ranging from 7.384 to 1.029 with other details are given for a large no. of minerals including many new detns. These with explanatory matter are given in English as well as in Russian. C. A. S.

Silver-bearing tetrahedrite in British Columbia. H. V. 5
Warren. *Mining Mag.* **60**, 123–5(1938); *Neues Jahrb. Mineral. Geol.*, Ref. I, **1938**, 562.—The "grey copper" of British Columbia is almost wholly tetrahedrite with a little tennantite. The chief impurities are Zn and Fe, the Zn especially is a disturbing factor in flotation processes. Ag-bearing tetrahedrite (freibergite) and Hg-bearing (schwazit with 6.6% Hg) are found. They are distinguished from ordinary tetrahedrite by a weaker luster and a red-brown streak; the Pb-bearing variety (malinowskite) is rare. Freibergite is the most important variety; 6
it is found with 5% Ag at many places in Canada, and always contains a considerable amt. of Zn, besides its chief constituents, Cu, Sb and S, and is assocd. with siderite, pyrite, arsenopyrite and sphalerite as older, and galena and Cu pyrite as younger, associates. C. A. S.

Weberite, a new mineral from Ivigtut (Greenland). Richard Bøgvad. *Medd. Grønland* **119**, No. 7, 11 pp. (1938); *Mineralog. Abstracts* **7**, 225(1939).—Weberite 7
occurs as pale-gray grains in cryolite and was first detected in the insol. residue with fluorite, topaz, quartz and mica; d. 2.96, *H* 3.5, monoclinic, n_α 1.346, n_β 1.348, n_γ 1.350, 2V 83° pos. Analysis: Al 11.65, Fe 0.37, Mg 10.43, Ca 0.08, Na 19.08, K 1.19, F 57.58, corresponding with Na_2MgAlF_7. C. A. Silberrad

The formula proposed for the mineral, vredenburgite. M. R. Anantanarayana Iyer. *Rec. Mysore Geol. Dept.* **34**, 8
75–84(1935)(Pub., 1936).—Partial analyses of 3 samples of vredenburgite and of the portions sol. and insol. in Na oxalate and H_2SO_4 are given and the formula, $a(Fe_2O_3.Mn_3O_3).b(Mn_3O_4.Fe_3O_4)$, is suggested. **A graphical representation of the composition of some manganese minerals including a discussion of the nature of the mineral vredenburgite.** *Ibid.* **35**, 73–85(1936)(Pub., 1937).—Minerals contg. Fe and Mn, and belonging to 3 classes represented 9
by bixbyite, jacobsite and vredenburgite, are plotted. Through *Mineralog. Abstracts* **7**, 208(1938). C. A. S.

Crystallization of merwinite in one Ural slag from a Martin furnace. D. S. Belyankin and L. I. Korchemkin. *Trav. inst. pétrog. acad. sci. U. R. S. S.*, No. **12**, 203–12 (1938); *Mineralog. Abstracts* **7**, 286(1939).—Tabular crystals of merwinite were found lining a cavity in a Martin furnace slag composed of monticellite, gehlenite and spinel. The merwinite, which contained about 15% of spinel, gave on analysis SiO_2 31.33, TiO_2 0.86, Al_2O_3 5.94, Fe_2O_3 7.28, MnO 5.66, MgO 11.20, CaO 36.25, Na_2O 1.48, K_2O 0.18; n_α 1.705, n_β 1.711, n_γ 1.724. C. A. S.

Petrography of slags rich in manganese. V. V. Lapin. *Trav. inst. pétrog. acad. sci. U. R. S. S.* No. **13**, 225–39(1938); *Mineralog. Abstracts* **7**, 285(1939).—Tephroite, γ- and β-2CaO.SiO_2, melilite, manganosite (n = 2.23), Mn-spinel and glass were detd. in a Mn-rich slag. Cf. Moskvin, *C. A.* **29**, 5779⁶. C. A. Silberrad

Mineralogical composition of a manganese-rich slag. D. S. Belyankin and I. M. Shumilo. *Trav. inst. pétrog. acad. sci. U. R. S. S.* No. **13**, 241–6(1938); *Mineralog. Abstracts* **7**, 286–7(1939).—There were sepd. from a Mn-rich slag: Mn-spinel, Al_2O_3 61.41, FeO 0.28, MnO 32.28, MgO 4.10, CaO 1.92; d. 3.98, n 1.79; Ca aluminate with Al_2O_3 75.0, CaO 20.20% monoclinic; and Mn aluminate with Al_2O_3 74.70, MnO 14.22, MgO 3.08 and BaO 4.52, d. 3.68, *a* 5, *c* 32 A. C. A. Silberrad

Nemalite from Lojane (Serbia). Miroslav Tajder. *Vesnik Geol. Inst. Jugoslavije* **6**, 239–40(1938)(in Croatian with German summary); W. F. de Jong. *Ibid.* 241–2; *Mineralog. Abstracts* **7**, 360(1939).—Nemalite occurs as fibrous aggregates in the Lojane chromite mine: analysis shows it to be $Mg(OH)_2$, n_α 1.5668, n_β 1.5690, n_γ 1.5890. X-rays show *a* 3.12, *c* 4.72 A., and that it is identical with brucite. C. A. Silberrad

Detrital diaspore in South Wales. J. C. Griffiths and Alan Stuart. *Geol. Mag.* **77**, 74–6(1940).—In a sandy boulder-clay at Ludchurch, Pembrokeshire, numerous grains of a platy colorless mineral detd. as disapore occur. It has d. more than 2.9, n_α 1.702, n_β 1.722, n_γ 1.748, and is assocd. with pyroxene, amphibole, staurolite, kyanite, brookite, anatase, topaz, garnet, apatite, muscovite and andalusite. Several of the grains are figured, and crystallographic details given. C. A. Silberrad

Leucite. E. Onorato. *Periodico mineral.* (Rome) 9, 85–97(1938); *Mineralog. Abstracts* **7**, 237–8(1939).—Leucite is monoclinic, with a unit cell, *a* 13.00, *b* 12.95, *c* 13.70, β 90°, contg. 16 mols. $KAl(SiO_3)_2$. The pseudocubic crystals are composed of twinned lamellae; it is optically orthorhombic. C. A. Silberrad

Cuprorivaite, a new mineral. Carlo Minguzzi. *Periodico mineral.* (Rome) **9**, 333–45(1938); *Mineralog. Abstracts* **7**, 225–6(1939); cf. *C. A.* **33**, 8145⁷.—The mineral occurs as blue grains in material from Vesuvius together with colorless quartz and green grains in white powdery calcite. Analysis of the blue grains (d. 2.866) gives SiO_2 62.51, Al_2O_3 2.95, Fe_2O_3 0.34, CuO 16.23, CaO 11.98, Na_2O 2.55, K_2O 1.00 and H_2O 2.43%. The green grains seem to be an alteration product of the blue. C. A. Silberrad

Tirodite. J. A. Dunn and P. C. Roy. *Records Geol. Survey India* **73**, 295–8(1938); *Mineralog. Abstracts* 7, 317(1939).—Tirodite, a new variety of amphibole, occurs at Tirodi (Central Provinces) as honey-yellow prisms in metamorphosed Mn ore intruded by granite, d. 3.312, H 6.5, n_α 1.629, n_β 1.639, n_γ 1.650. Analysis: SiO_2 53.26, Al_2O_3 1.25, Fe_2O_3 2.63, FeO 1.06, MnO 8.25, MgO 31.26, CaO 1.11, Na_2O 1.56, K_2O 0.07, H_2O 0.05. It differs from dannemorite and richterite by contg. more Mg. C. A. Silberrad

Emerald deposits of Sverdlovsk mining district (Urals). N. M. Uspenskiĭ. *Ann. inst. mines* (Leningrad) 11, 161–97(in English, 197–205)(1938); *Mineralog. Abstracts* **7**, 332–3(1939).—The emerald mines are in the Monetnaya range some 70 miles N. N. E. of Sverdlovsk (Ekaterinburg). They are in a complex of metamorphic rocks amphibolites, etc., with large lenses of talcose rocks contg. relics of serpentine and peridotite. These are surrounded by intrusions of granite and gabbro-diorite whence various pegmatitic veins penetrate the metamorphic rocks. The fluorite-beryl veins are of late formation at temp. of probably 200–500°. The rocks with 42 minerals occurring therein are described. C. A. S.

Phillipsite from basalts of N. E. Bohemia. Karel

Tuček. *Sborník Národního Musea v Praze (Acta Musei Natl. Pragae)* **1B**, 85–90(1938)(in English with Czech summary); *Mineralog. Abstracts* **7**, 347(1939).—Two interesting occurrences of phillipsite are described near Nová Paka; one at Kumburk Hill, externally transparent, internally opaque crystals 3–4 mm. across; the other at Stupná, small crystals n 1.49, d. 2.28. C. A. Silberrad

Aegirite-augite in natrolite veins in the dolerite from Nemuro (Hokkaido). J. Suzuki. *J. Faculty Sci., Hokkaido Imp. Univ.*, Ser. IV, No. 2(1938); *Neues Jahrb. Mineral., Geol.* Ref. II, 1938, 863.—An example of metasomatic transformation of ordinary augite in aegirite-augite by the action of soda-rich residual solns. into a dolerītic rock is described. It is schematically represented by: 4 mol. ordinary augite + 2 mol. labradorite-bytownite + 3NaOH + $8SiO_2$ + CO_2 + O → 1 mol. aegirite-augite + $4CaCO_3$ + 3 mol. albite, and 1 mol. albite + $2H_2O$ → 1 mol. natrolite + $3SiO_2$. C. A. Silberrad

Clinochlore from Dobro Polje. Miroslav Tajder. *Vesnik Geol. Inst. Jugoslavije* **6**, 235–8(1938)(in Croatian with German summary); *Mineralog. Abstracts* **7**, 359–60(1939).—Green scales of clinochlore form veins in serpentine; analysis: SiO_2 30.62, Al_2O_3 17.51, Fe_2O_3 1.60, FeO 3.62, MnO 0.35, MgO 32.35, H_2O + 12.62, H_2O − 1.54; n (mean of α and β) 1.583, $\gamma - \alpha$ 0.0088. C. A. Silberrad

Nontronite from weathered crust on slopes of Northwestern Altai. G. D. Afanas'ev. *Trav. inst. pétrog. acad. sci., U. R. S. S.* No. 7–8, 135–53(1936); *Mineralog. Abstracts* **7**, 104(1938).—A green clay from the weathered zone consists of chromo-ferric beidellite. The av. of 2 analyses gives SiO_2 41.75, TiO_2 0.58, Al_2O_3 17.30, Cr_2O_3 0.60, Fe_2O_3 15.45, FeO 0.45, MgO 0.63, BaO 0.04, CaO 7.52, Na_2O 0.10, K_2O 0.48, H_2O + 5.81, H_2O − 8.67; n_α = 1.559, n_β = n_γ = 1.587; pleochroism marked. The heating curve shows arrests between 92° and 120°, between 463° and 553° and at 911°. The relation to kaolinite is discussed. C. A. Silberrad

The petrography of some English fuller's earths and the rocks associated with them. E. F. Newton. *Proc. Geol. Assoc. London* **48**, 175–97(1937); *Mineralog. Abstracts* **7**, 98–9(1938).—Several English occurrences of fuller's earth are described with complete analyses of colorless cleavage flakes sepd. from 2 of them, the compns. of which are $Or_6Ab_9An_2$ and $Or_7Ab_{10}An_2$. Sphene, zircon, apatite and zinc blende occur in the earths in practically unworn condition. The earths were probably deposited through chem. action in shallow water, free from normal sedimentation. C. A. Silberrad

Thulite from Myôzinzima, Sisakazima Islands, Japan. Toyohumi Yosimura. *J. Faculty Sci. Hokkaido Imp. Univ.*, Ser. 4, **4**, 17–22(1938); *Mineralog. Abstracts* **7**, 358.—The thulite occurs in pink spots and minute crystals at the contact of pegmatite and aplite with limestone and amphibolite in gneisses. It is apparently derived from the epidote in the basic rocks: n_α 1.705, n_γ 1.710, d. 3.23; the analysis is given, corresponding with $H_2(Ca, Fe)_4Al_6Si_6O_{26}$. C. A. Silberrad

Teineite. Toyohumi Yosimura. *J. Faculty Sci. Hokkaido Imp. Univ.*, Ser. 4, **4**, 465–70(1939); *Mineralog. Abstracts* **7**, 316.—Teineite, a new tellurate mineral, occurs as sky-blue prismatic crystals up to 1 cm. long together with tellurite in the oxidized portions of Te veinlets in the Teine mine, Hokkaido. It is orthorhombic $a:b:c$ 0.705:1:0.786, d. 3.80, H 2.5, n_α 1.767, n_β 1.782, n_γ 1.791; analysis: TeO_3 48.0, SO_3 6.6, CuO 28.0, H_2O 12.2, insol. 6.1, corresponding with $Cu(Te,S)O_4.2H_2O$ (cf. Watanabe, *C. A.* **27**, 3684). C. A. S.

Wulfenite from Kravarica-Tal (Serbia). Ljudevit Barić. *Vesnik Geol. Inst. Jugoslavije* **7**, 205–15(1938); *Mineralog. Abstracts* **7**, 360(1939).—Minute yellow crystals of wulfenite occur with sulfides in limestones invaded by trachyte at Kravarica, near Krepoljin in N. E. Serbia. C. A. Silberrad

Fulgurites from Witsands (S. E. Kalahari). A. D. Lewis. *S. African Geogr. J.* **19**, 50–7(1936); *Mineralog. Abstracts* **7**, 106(1938).—In 8 sq. m. of sand dunes some 2000 fulgurites are estd. to occur, many in broken fragments, but 5 were excavated to a depth of 8 ft. and their ends not reached. The av. thickness of the fused walls is 0.035 in. The mode of formation is discussed. C. A. Silberrad

Tektites and pseudotektites from Dutch East Indies and Philippines. Catherine M. Koomans. *Leidsche Geol. Meded.* **10**, 63–81(1938); *Mineralog. Abstracts* **7**, 275–6(1939).—Analyses of tektites from the Philippines, Java and Siam, of pseudotektites (pseudo-Americanites) from Patagonia and the Philippines, and of obsidian pebbles from Java and Sumatra are given. Tektites are completely glassy, pseudotektites contain crystallites; the surface sculpture of both is due to corrosion in the soil. The compn. of tektites is considered to resemble that of sedimentary, and that of pseudotektites that of igneous, rocks. C. A. Silberrad

Some new carbon minerals—kansasite. John D. Buddhue. *The Mineralogist* (Portland, Ore.) **6**, No. 1, 7–8, 20–2(1938); **Jelinite and associated minerals.** *Ibid.* No. 9, 9–10; *Mineralog. Abstracts* **7**, 265(1939).—A fossil resin, d. 1.05–1.06, from shale assocd. with coal seams near Ellsworth (Kansas) was first named kansasite, and later renamed jelinite. The soly. behavior of amber (d. 1.085) from Equilleres, Basses Alpes, France, differs from that of Baltic amber in its reaction to solvents and is named *pseudosuccinite*. For hartite (*C. A.* **17**, 2255) the formula $C_{18}H_{32}$ is suggested. C. A. Silberrad

Composition of meteors. John D. Buddhue. *Popular Astronomy* **45**, 166–9(1937); *Mineralog. Abstracts* **7**, 64(1938).—Spectra of comets show the presence of C, N, O, Na and probably Fe and H; those of meteors of Fe, Mg, Ca, Mn, Si, Cr, Al and probably Co, Na, Ni, C, H, O, N and S. The meteoritic dust found as magnetic spherules in deep-sea deposits and on the Greenland ice contains Fe, Co, Mg and Si. C. A. Silberrad

The Benld meteorite, Illinois No. 2. Ben Hur Wilson. *Popular Astronomy* **46**, 548–58(1938); *Science* **89**, 34–5(1939); *Mineralog. Abstracts* **7**, 273(1939).—The meteorite fell on Sept. 29, 1938, wt. about 4 lb. It has a velvety black crust 0.5–1.0 mm. thick, with dark-gray interior, well-developed chondrules and specks of metal; d. 3.69. C. A. Silberrad

Microscopic examination of the Lowicz meteorites. Maria Kołaczkowska. *Arch. minéral. soc. sci. Varsovie* **14**, 47–51(in German)(in Polish, 52–6)(1938); *Mineralog. Abstracts* **7**, 174–5(1938).—The brecciated silicate grains are olivine, plagioclase and pyroxenes (both orthorhombic and monoclinic). From the d. the metal content of 2 pieces is calcd. as 71 and 53.5%. A polished surface shows in places green phosphorescence after exposure to x-rays. C. A. Silberrad

Opaque constituents of the Lowicz meteorites. Stanisław Jaskólski. *Arch. minéral. soc. sci. Varsovie* **14**, 15–36(in German)(in Polish, 37–46)(1938); *Mineralog. Abstracts* **7**, 174–5(1938).—These include grains of kamacite showing Neumann lines with a little taenite bordering plessite, and accessory schreibersite, chromite, troilite and ilmenite, the last often as rods enclosed in chromite. C. A. Silberrad

Spectroanalytic investigation of the Lowicz meteorites. H. Moritz. *Arch. minéral. soc. sci. Varsovie* **14**, 65–8(1938); *Mineralog. Abstracts* **7**, 174–5(1938).—Spectrum analysis showed the presence of 26 elements, usually in amts. less than 0.001%. C. A. Silberrad

Chief constituents of the Lowicz meteorites. St. J. Thugutt. *Arch. minéral. soc. sci. Varsovie* **14**, 57–60(in German)(in Polish, 61–4)(1938); *Mineralog. Abstracts* **7**, 174–5(1938).—Analysis of the metallic portions gave Fe 91.09, Ni 8.51, Co 0.50 and insol. 0.53. Analyses of the anorthite, olivine (d. 3.4065), and pale-green bronzite are given. C. A. Silberrad

Radium content of the Lowicz meteorites. Jan Ciechocki. *Arch. minéral. soc. sci. Varsovie* **14**, 69–74(1938); *Mineralog. Abstracts* **7**, 175(1938).—The Ra content of these meteorites is less than 10^{-12}. C. A. Silberrad

New light on the Glorietta, New Mexico, meteorite.

H. H. Nininger. *Am. J. Sci.* **238**, 56–60(1940).—This meteorite is a combination siderite and pallasite. The Pojoaque and Santa Fe meteorites are fragments of the Glorietta. Alden H. Emery

Mexican minerals. Carlos F. de Landero. *Mem. rev. acad. nacl. cienc. Antonio Alzate* **54**, 385–99(1934)(Pub., 1938).—A general historical outline of the development of mining and metallurgy in Mexico from the Spanish conquest is followed by monographic treatment of the history of a no. of Mexican minerals. A. H. Krappe

The diamond deposits of Sierra Leone. J. D. Pollett. *Bull. Imp. Inst.* **35**, 333–48(1937); *Mineralog. Abstracts* **7**, 127–8(1938).—The rocks of the diamondiferous area are granites (? pre-Cambrian) invading schists and intruded by dolerite. The diamonds are usually octahedral, less frequently dodecahedral and rarely cubic. Assocd. minerals are corundum, zircon, ilmenite, epidote, rutile, garnet and occasionally spinel and chrysoberyl. The last 2 are mainly at the granite-schist contacts. C. A. Silberrad

The Gwanda gold belt. R. Tyndale-Biscoe. *Rept. Geol. Survey Southern Rhodesia* No. **30**, 33 pp.(1937); *Mineralog. Abstracts* **7**, 155–6(1938).—The belt consists of ancient schists, quartzites and ironstones, enveloped by granite. Au occurs in all the older rocks except serpentine, and in the granite near its contact with the schists. Some 70 mines or claims are described. C. A. Silberrad

The ore deposits of the Sudetenland, their origin and economic importance. A. Watznauer. *Mitt. Ver. Naturfr. Reichenberg* **60**, 20–8(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 763–5.—A brief account is given of the ores of Sudetenland. Those of the Erzgebirge contain predominantly Cu with a little Ag, Sn, W and U; while in the Riesen- and Isergebirge Cu ores also predominate, thus near Wernsdorf 600,000 tons of ore averaging 2.74% of Cu is visible, and elsewhere there are smaller quantities of ores of Pb (also contg. Ag), Sn and Fe and a little Au. C. A. Silberrad

Natural resources and mining in the former German colonies. F. Friedensburg. *Tech. u. Wirtschaft* **31**, 24(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 767–8.—Brief accounts are given of the minerals so far discovered in Togo (Fe, Au and bauxite), Cameroons (Au and Sn) and southwest Africa (Au, Cu, V, Li-mica, wolfram, tantalite, magnetite and diamonds). C. A. Silberrad

Minerals from Gyöngyösoroszi. Kálmán Sztrókay. *Földtani Közlöny* **68**, 30–2(1938); *Mineralog. Abstracts* **7**, 117(1938).—Hydrothermal veins in pyroxene-andesite contain galena, sphalerite, fluorite, dolomite, quartz, amethyst, pyrite and barite. C. A. Silberrad

Mines and mineral resources of Newfoundland. A. K. Snelgrove. *Newfoundland Geol. Survey, Information Circ.* No. **4**, 1–162(1938); *Mineralog. Abstracts* **7**, 117(1938).—The most important ores, etc., some of which are worked, are of Fe, Cu, Zn, Pb and fluorite, and in smaller amts. of Au, Ni and chromite. These are described with the minerals found. C. A. Silberrad

The lead-zinc deposit of Trebice-Lipovica (Raška-Novi Pazar). St. Pavlovitch *Bull. serv. géol. roy. Yougoslav.* **6**, 247–60(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 636.—The deposit lies in more or less propylitized hornblende-andesite, which has resulted in the formation of epidote, chlorite, sericite and carbonates; the vein walls consist of carbonates—smithsonite, siderite and calcite, which occasionally form nests in the vein. The richest vein at Trebiće, 0.5 m. wide to a depth of some 19 m., contains pyrite and marcasite with recent smithsonite and siderite, sphalerite, galena and Cu pyrite. In depth it decreases to 3–4 cm. and contains galena, pyrite and sphalerite with quartz as gang. At 3-m. depth the ore averages Zn 25.80%, Pb 12.75, with Ag 140 g. and Au 1.9 g./ton. Three phases are distinguished: resulting in the formation of (1) quartz, pyrite, galena and sphalerite, (2) lamellar pyrite and marcasite and (3) Pb and Zn carbonates. The deposit is of hydrothermal origin. C. A. Silberrad

Galena at Mežica. M. Munda. *Rudarski Zbornik* [2], **2**, 79–90(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 751–2.—The fissures and fault-breccias of the Zn-Pb deposit of Mežica (Miess, Carinthia) contain foliated galena, owing to pressure. Examn. of polished sections shows the galena to have behaved as a plastic mass in which sphalerite, calcite and pyrite are embedded, the pressure causing twins to form in the sphalerite and calcite, or to cause them to be deformed cataclastically. C. A. Silberrad

Two finds of ore in the Mesozoic of Mt. Djumbir, Nizhna Tatra (Slovakia). V. Zoubek. *Věstník Státního Geol. Ústavu, Č. S. Rep.* **13**, No. 4/5(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 776.—A vein of galena and tetrahedrite contg. also barite has been proved on the south side of Mt. Djumbir, and cupriferous siderite and ankerite in neighboring cryst. rocks. C. A. Silberrad

Ores of the Buron (Caucasus) deposit. F. I. Abramov, I. S. Volynskiĭ, I. A. Pudovkina and S. Solomkina. *Tsvetnye Metal.* **1938**, No. 1, 10–21; *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 615–16.—The deposit occurs in pre-Paleozoic metamorphic rocks, mica-quartz-sericite schists, between granite and Jurassic keratophyres and tuffs. The chief minerals are pyrite (often 40–50, sometimes 75–80% of the total ore), pyrrhotite (av. 15–20%), magnetite, sphalerite, chalcopyrite, galena (with which last 3 the pyrrhotite is closely connected) and arsenopyrite. Accessory minerals are cassiterite, tetrahedrite, bismuthinite, native Bi, secondary pyrite and goethite. The gang includes quartz, calcite, chlorite and tourmaline. A tabular scheme for sepn. of the ores is given. C. A. S.

Distribution of minerals of different types in the Buron deposit. F. I. Abramov, I. S. Volynskiĭ, A. D. Maslennikov and I. A. Pudovkina. *Tsvetnye Metal.* **1938**, No. 3, 15–23; *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 616–17.—The deposit consists of 2 lenses averaging 9.58 and 5.00 m. thick in which 6 types of ore are described: compact pyrite with (1) magnetite or (2) pyrrhotite, (3) compact pyrrhotite, (4) disseminated pyrite, (5) disseminated pyrrhotite with chalcopyrite and (6) disseminated galena. One occurs in the center of the deposit, 5 occur at the sides and 3 between them. C. A. S.

The iron and manganese ores of Central Brazil. K. Endell. *Tech. Blatter* **1936**, 842; *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 294.—Valuable deposits of Fe and Mn extend over an area 125 × 160 km. in the state of Minas Geraes, some 200 m. north of Rio, from Itabira do Matto Denho to Queluz. At Casa de Pedra some 10^8 tons of hematite is in sight which can be largely worked in open pits. C. A. Silberrad

Manganese ore in the Banjalucka Kozara (N. Bosnia). T. Jakšić. *Rudarski Zbornik* No. **2**, 1, 1–12(1938)(in Croatian with French summary); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 648–9.—The ore is mainly psilomelane, with a little pyrolusite, the former is oölitic of syngenetic and partly epigenetic origin. It is best developed at Bache Bajinac where it forms a bed averaging 1 m. thick, but in places 2.5. Some 600 tons has so far been extd. of av. compn. Mn 40.71–51.20, Fe 3.33–6.32, SiO_2 9.0–21.8 and H_2O 3.60–12.48%. The amt. in sight is estd. at 480,000 tons. C. A. Silberrad

Manganese minerals of Prełuczny. Roman Krajewski *Bull. service géol. Pologne* No. **2**, 1–28(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 440.—The Mn ores of Prełuczny, in the eastern Polish Carpathians, occur at the contact of gneiss and cryst. schists. They consist of rhodocrosite, rhodonite and manganiferous hornblende to a total estd. amt. of 16,555 tons. On the av. the ore contains Mn 30%, Fe 8, SiO_2 23 and CO_2 6–16. They appear to have resulted from the interaction of org. SiO_2 and manganiferous mud at the sea bottom. In the cryst. schists in the neighborhood sulfidic ores of Cu, Pb and Zn occur. C. A. Silberrad

Molybdenum in the Upper Silurian alum schists of East Thuringia. Rudolf Hundt and W. Krebs. *Z. prakt. Geol.* **46**, 111–12(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 562–3.—MoO_3 occurs in soln. in a spring near Saalfeld, and also in an ocherous deposit there. Either there must be Mo-contg. minerals in some of the

neighboring veins or in the Silurian rocks. Nearly every analysis of the Upper Silurian alum schists of East Thuringia shows the presence of Mo, the amt. probably varying with the amts. of C, pyrite and marcasite. C. A. S. 1

Radium-containing uranium ore from Timor. C. E. A. Harloff. *Ing. in Nederl.-Indië* **5**, IV. *Mijnb. en Geol. "De Myning"* **1938**, 67; *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 794; cf. *C. A.* **31**, 6144⁷.—The supposed find of Ra-bearing U ore in Timor is an error owing to a mistake in a museum. The ore is identical with a wulfenite-contg. sklodowskite from Katanga (Congo), and must have come from there. C. A. Silberrad 2

Bauxite of Poços de Caldas. M. da Silva Pinto. *Boll. do S. F. P. M.* (Rio de Janeiro) No. 22 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 647; cf. *C. A.* **33**, 2853².—The high plateau of Poços de Caldas (Minas Geraes, 250 m. W. N. W. of Rio) consists essentially of foyaite and phonolite, the surface of which through extensive post-Tertiary weathering has been lateritized with production of a layer of bauxite 3–5 m. thick beneath some 30 cm. of a sterile layer. There is no "iron hat," and the transition to the underlying parent rock is very sharp. The av. compn. of the laterite is Al_2O_3 60, Fe_2O_3 5–7, TiO_2 2, SiO_2 1 and H_2O 30%. The Fe content is almost identical with that of the parent phonolite The total amt. of bauxite is estd. at 16×10^7 tons. C. A. Silberrad 3

Memorandum on the occurrence of bauxite in British Guiana. D. W. Bishopp. *Geol. Survey Brit. Guiana Bull.* No. 8, 67 pp. (1938); *Ceram. Abstracts* (in *J. Am. Ceram. Soc.*) **18**, 312 (1939) —A compilation of information that has been published since 1910. The deposits are described and their geology and origin are discussed. Analyses are included. E. H. 4

Onyx-marble deposits and connected springs of San Rafael, Argentina. Richard Stappenbeck. *Z. prakt. Geol.* **45**, 203–10 (1937); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 637–8.—Seven occurrences of onyx marble in the foothills of the Andes near San Rafael in Mendoza are described. They are all near mineral springs the waters of which contain Ca, Mg, Fe, Mn and Co, and which have genetic connection with neighboring outpourings of basalt. Aragonite replaces calcite in places, indicating variation in temp. The water of one spring contains traces of Br. C. A. Silberrad 5

Onyx marble and aragonite in the neighborhood of Tetovo (S. Serbia). Fran Tućan. *Jugoslaw. Akad. Wiss. u. Kunst, Rad* **261**, 33–54 (1938); *Neues Jahrb. Mineral. Geol.*, Ref. II, **1938**, 638–40.—In the springs near Tetovo large quantities of onyx marble (I), calc sinter (II) and aragonite (III) are formed. Their structures are minutely described. Analyses are given showing in I 4.48% of FeO and 0.15 MnO, and in III 0.17% SrO and 0.11 of BaO. III is converted to calcite by heating for 30 min. at 400°, 5 hrs. at 380° or 36 hrs. at 350°. II consists almost entirely of calcite but contains in cracks a few crystals of III. C. A. Silberrad 6

Determination of translucency of marble. G. Gerth and W. Prüfer. *Stein-Ind. u. Strassenbau* **33**, 20 (1938); *Neues Jahrb. Mineral. Geol.*, Ref. II, **1938**, 391–2.—Various com. marbles are classified according to their degree of translucency, for measuring which an arrangement depending on a Se photocell is described. The translucency depends on the structure, color and presence of other minerals; coarsely cryst. marble is more transparent than the finely cryst. variety. C. A. Silberrad 7

The "Heinrichsfreude" seam No. 4 of the Szyby Piast mine at Ledzini (Upper Silesia). A. Bolewski. *Bull. serv. géol. Pologne* **9**, No. 1 (1937); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 699.—In the middle of this seam fireclay forms a stratum 20–40 cm. thick; it is described as laterite; small masses, showing rhythmic pptn., consist of $Al(OH)_3$ 25–32%, and Al silicate 42–43%; SiO_2 is present as chalcedony; Seger cone 32–36. Similar material occurs in the hanging wall and in the clayey coal, which is considered to have originated as organically coagulated suspensions and solns. C. A. Silberrad 8

Minerals of the Mansfeld copper schists. Heyer. *Kohle u. Erz* **35**, 361–5, 413–16 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 438–9.—The Mansfeld Cu schists consist of 55% quartz and clay, 24% limestone and dolomite, 10% org. material, 10% sulfidic ores and 1% gypsum. The chief minerals are bornite, chalcopyrite, chalcocite, covellite, azurite, malachite, cuprite, tile-ore and native Cu. A list of 44 other minerals found is given. C. A. Silberrad 9

Mechanical and mineralogical constitution of sands of the Saane River (Switzerland). August Müller. *Ber. schwyz. naturforsch. Ges.* **2**, 78 pp. (1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 832.—In the 0.25–0.1 mm. fraction of the sand of the Saane River 30 minerals were identified in addn. to quartz, feldspar and calcite. Crystallographic and morphological descriptions are given. C. A. Silberrad 10

The sands of East Greenland. Armin v. Moos. *Medd. Grønland* **103**, No. 4, 76 pp. (1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 832–3.—Sands from 3 localities were examd. They contained in addn. to quartz, ores and garnet, (1) feldspar, mica, hornblende and epidote; (2) carbonates, clay slate, zircon, titanite, tourmaline and rutile; and (3) epidote and apatite. C. A. Silberrad 11

Asphalt rock from Dubrovnik. F. Schwarz. *Berg- u. hüttenmänn. monatsh. montan. Hochschule Leoben* **86**, 113 (1938); *Neues Jahrb. Mineral. Geol.*, Ref. II, **1938**, 727–8.—This asphalt rock consists of brecciated limestone with 13.9% of asphalt in the interstices. It is unlikely to become a source of oil, but crushed should be useful for *road making*. C. A. Silberrad 12

Petroleum and asphalt. III. The composition of petroleum. B. The methanes. N. Wing-Easton. *Geol. en Mijnb.* **16**, 99–103 (1938); *Neues Jahrb. Mineral. Geol.*, Ref. II, **1938**, 710; cf. *C. A.* **33**, 3303¹.—Various theories of the origin of petroleum are discussed and the actual process is considered to be probably more complicated, the various intermediate products acting and reacting with each other, while the catalytic effect of such substances as V, I, SiO_2 and C which may be present, and bacterial action require consideration. The theories of the origin of sapropel-coal from planktonic material, and of coorongite are discussed. Lastly it is suggested that the predominance of naphthenes in Tertiary and of paraffins in earlier oils is due to the fact that in the earlier plants cellulose, and in the latter lignin, predominates. C. A. Silberrad 13

Geological thermometry. Einar Jensen. *Tids. Kjemi Bergvesen* **19**, 91–4 (1939).—A review on methods for detn. of the temp. at which minerals are formed. H. Kringstad 14

The contribution of differential pressures to magmatic differentiation. R. C. Emmons. *Am. J. Sci.* **238**, 1–21 (1940).—During crystn. of magmatic liquid the crystals and liquid phase may have very different compns. Differentiation requires the phys. sepn. of these 2 phases. Such sepn. through pressure differentials created by fracturing of brittle wall rocks is believed to be a leading process in sepn. of granitic liquid from more basic crystals. Alden H. Emery 15

Barium in the igneous rocks of the Ukraine. P. I. Lebedev. *Trav. inst. pétrog. acad. sci. U. R. S. S.* No. 12, 155–71 (1938); *Mineralog. Abstracts* **7**, 299 (1939).—In the charnockite series BaO varies between 0.20 and 0.48%, in the monchiquite-camptonite between 0.16 and 0.68%, and is very small in amt. in the nephelite-syenite. The distribution is compared with that in other regions. C. A. Silberrad 16

Viscosity of molten mixtures of diabase and picrite. M. P. Volarovich and R. S. Fridman. *Trav. inst. pétrog. acad. sci. U. R. S. S.* No. 13, 197–201 (1938); *Mineralog. Abstracts* **7**, 297–8 (1939).—The viscosity of diabase-picrite mixt. at 1200–1300° increases with addn. of picrite and between 1300° and 1400° is a max. for 20% picrite. C. A. Silberrad 17

Moving and contraction forms of lava. F. Bernauer. *Z. Volkanol.* **17**, 237–75 (1938); *Neues Jahrb. Mineral. Geol.*, Ref. II, **1938**, 432–4.—The various forms assumed by 18

solidifying lavas are discussed, as deduced from observations at Vesuvius, Etna and the Lipari Islands. C. A. Silberrad

Petrography of the ore-bearing region of Altai and of Kalba. N. A. Eliseev. *Petrograph. Inst. F. Yu. Levinson-Lessing, Acad. Sci. U. S. S. R., Petrography of U. S. S. R., Ser. I, Regional Petrography* **6**, 248 pp. (1938); *Mineralog. Abstracts* **7**, 303.—A detailed account of the igneous, metamorphic and sedimentary rocks of the western Altai, including the Palaeozoic spilite-keratophyre series, various intrusive and contact-altered rocks. 88 analyses. C. A. Silberrad 2

Petrography of northeastern Altai. A. P. Lebedev. *Trav. inst. pétrog. acad. sci. U. R. S. S.* No. **13**, 77–103 (1938); *Mineralog. Abstracts* **7**, 302.—The igneous and metamorphic rocks of the lake Telezkoe region are described and 4 analyses given. C. A. Silberrad

Vesuvius in July, 1937. Karl Höhn. *Z. Volkanol.* **17**, 283–5(1938); *Neues Jahrb. Mineral. Geol.*, Ref. II, **1938**, 438.—A small new crater has appeared to the west of the cinder cone, whence a const. stream of steam and HCl is emitted. Marked activity was observed in the main crater with emission of several lava streams. C. A. S. 3

New alkaline intrusive body on Kola Peninsula. N. I. Soustov. *Trav. inst. pétrog. acad. sci. U. R. S. S.* No. **12**, 89–105(1938); *Mineralog. Abstracts* **7**, 300–1.—An intrusion of alkali-syenite and nephelite-analcite-syenite occurs south of the Khibina tundra (Kola Peninsula). Crystn. of microcline-perthite and nephelite was followed by cataclastic effects, and late magmatic products (analcite, cancrinite, calcite, albite, biotite and fluorite) filled the cracks, partially replacing feldspar and nephelite. Two complete analyses C. A. Silberrad 4

A new Kamchatka rock. A. I. Morozov and N. N. Shavrova. *Bull. Kamchatka Volcanol. Sta. Acad. Sci. U. S. S. R.* **1938**, No. 3, 19–20; *Mineralog. Abstracts* **7**, 304(1939).—*Kamchatite* is a porphyritic igneous rock from the Sredinnyi range in Kamchatka. It consists of orthoclase (large phenocrysts), bluish hornblende, pyroxene and epidote. Analysis gives SiO_2 51.70, TiO_2 0.47, Al_2O_3 13.13, Fe_2O_3 2.29, FeO 6.03, MnO 0.19, MgO 3.61, CaO 8.13, BaO 0.16, Na_2O 1.95, K_2O 6.24, P_2O_5 0.14, H_2O −0.09, loss on ignition 1.92. It is thus chemically similar to potash-rich monzonite or shonkinite, but contains no plagioclase. C. A. Silberrad 5, 6

The pegmatite area south of the Orange River, Namaqualand. T. W. Gevers, F. C. Partridge and G. K. Joubert. *Mem. Geol. Survey, S. Africa* No. **31**, 172 pp. (1937); *Mineralog. Abstracts* **7**, 338–9(1939); cf. *C. A.* **32**, 1619[3].—The pegmatite veins occur over some 10 miles between Goodhouse and Vioolsdrift, the longest being over a mile by 50 yards in width. The chief replacement processes are muscovitization, albitization and lithianization. Bi veins in greisen and highly quartzose pegmatites, and beryl and scheelite in quartz-tourmaline veins are described; as also occurrences of chrysoberyl, phenakite, bertrandite, spessartine, tantalite-columbite, euxenite, monazite, xenotime, uranophane, soddyite, a mineral near pyrochlore, rutile, spodumene, lepidolite, lithiophilite, bismuthinite, bismoclite, sphene, daphnitic chlorite, zoisite, prehnite, epidote and apatite. Nonpegmatitic deposits of Cu ores, amethyst and tremolite are also described. Chem. analyses of several of the rarer minerals are given. C. A. Silberrad 7, 8

Granites of Scotland. J. G. C. Anderson and M. Macgregor. *Mem. Geol. Survey, Gt. Brit.* **32**, 1–70(1939).—An account of the economically important occurrences of granite in Scotland, including as such all medium or coarse-grained light-colored igneous rocks with an appreciable (say 5%) content of quartz, thus including tonalites or quartz-diorites. Five typical analyses are given and the results of various tests of 16 of the chief varieties, and also brief accounts of the methods of quarrying. C. A. Silberrad 9

Structure and petrographical composition of the Lovozersky tundras. N. A. Eliseev, I. V. Zelenkov, N. K. Nefedov and V. A. Unksov. *Bull. acad. sci. U. R. S. S., Classe sci. math. nat., Sér. géol.* **1938**, 235–68; *Mineralog. Abstracts* **7**, 301–2(1939); cf. Gerasimovskiĭ, *C. A.* **32**, 1614[7]; Chirvinskiĭ, *C. A.* **32**, 6198[7].—The plutonic complex of Lovozero (Luyavrurt) is intruded into pre-Cambrian and Devonian rocks, which have been thermally altered at the contact. The intrusion consists of various phases: (1) various nephelite-syenites, tawite, urtite and juvite; (2) loparite-bearing foyaite, urtite and luijaurite; (3) eudialyte-bearing luijaurite; and (4) a late dike complex principally represented by monchiquite and tinguaite. Several modal analyses are given. C. A. Silberrad 1

Dolerite plugs in Antrim (Ireland). S. I. Tomkeieff. *Geol. Mag.* **77**, 56–64(1940).—Two dolerite plugs (I) at Tieveragh, into Old Red Sandstone, and (II) at Tievebulliagh, into older lavas (olivine-dolerite and olivine-basalt), and the resulting metamorphism caused (*a*) in the intruding dolerite, and (*b*) in the rock intruded into, are described in detail: I(*a*) the dolerite has become almost olivine-free and fine-grained while the pyroxene shows an approach to pigeonite; I(*b*) in the sandstone buchite has been formed with cordierite, and clino- and ortho-pyroxenes; II(*a*) the olivine-dolerite of the plug shows a definite decrease in granularity toward the contact, where it passes into basalt; II(*b*) in the lavas intruded into there is serpentinization of the olivine, albitization of plagioclase and formation of porcellanite. C. A. Silberrad

Sanidinedacite of Zvecan and Sokolica and alum-rock of Boljetin near Kosovska-Mitrovitza. Fran Tućan. *Jugoslaw. Akad. Wiss. u. Kunst, Rad* **261**, 137–82(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 817–19.—The sanidinedacite of Zvečan is really a liparite contg. phenocrysts of sanidine measuring up to 5 × 2 cm.; phenocrysts of andesite are almost as numerous; inclusions of hornblende, pyroxene, titanite and calcite occur in the sanidine, and the two first named and occasionally quartz occur also as phenocrysts. These are all described in detail with analyses and crystallographic details. What T. calls sanidinedacite occurs at Sokolica; it contains concretions of corundum and hypersthene (both pleochroic). Further N. E. near Boljetin, the sanidinedacite has been completely pneumatolytically and hydrothermally metamorphosed, part being completely silicified, and part alunitized (I) or kaolinitized (II) resulting in rocks contg., resp. (I) 10.87% SO_3, and (II) 75.36% SiO_2, and 17.4% Al_2O_3 with only a trace of Fe_2O_3. C. A. Silberrad 4

Rhön trachyte tuff. F. v. Wolff and W. Jäger. *Jb. halleschen Verbandes* **16**, 13–24(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 822.—The clayey portion of the Rhön trachyte tuff, consisting of volcanic glass and fragments of sanidine, augite, hornblende and biotite, was centrifuged into heavier and lighter fractions, the latter consisting of amorphous substances and muscovite flakes; analysis showed this portion to contain little MgO or CaO, which enables it to absorb Mg and Ca ions and explains its good hydraulic setting powers in their presence. C. A. Silberrad 7

Two remarkable tephrites and a basalt from N. W. Bohemia. A. Senger. *Firgenwald* **11**, 119–22(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 902.—The tephrites are leucite-hauynite-tephrite occurring on the W. slope of the Schlossberg in rolled nodules, and hauynite-leucite tephrite, contg. 10–15% of leucite, found near Rabenstein. They are minutely described. A basalt consisting of glass with microlites of feldspar and augite and phenocrysts of diopsidic augite, olivine and plagioclase occurs near Schönbach. C. A. Silberrad 8

Basalts of Cheskaia Bay. Z. A. Sazonova. *Trav. inst. pétrog. acad. sci. U. R. S. S.* No. **12**, 107–54(1938); *Mineralog. Abstracts* **7**, 302(1939).—These basalts are described with several analyses. Attention is specially paid to the chloritic mesostasis (palagonite) found in them. It is suggested that the palagonite is of later magmatic origin, spheroids thereof being attributed to liquation differentiation of the residual magma. C. A. Silberrad 9

Basic rocks of the Pindus and western Macedonia. Jan H. Brunn. *Compt. rend.* **210**, 109–11(1940).—The rocks of the axis of the N. W. portion of the Pindus range are basic and include lherzolites, spilites, dolerites and

scoriaceous basalt, all not or very little serpentinized, thus differing from the similar rocks of the Albanian continuation of the range. Elsewhere outcrops of dolerite and basalt occur and in places similar rocks with harzburgite and gabbros, which are more visibly connected with volcanic vents, these latter occurrences being often assocd. with radiolatites and Cretaceous limestones.
C. A. Silberrad

The pyroxenite intrusion near Africanda Station on the Kola Peninsula. B. M. Kupletskiĭ. *Trav. inst. pétrog. acad. sci. U. R. S. S.* No. 12, 71–88(1938); *Mineralog. Abstracts* 7, 301(1939).—A small igneous complex intrusive in Archaean gneiss is composed of pyroxenite, olivinite rich in titanomagnetite and knopite (cf. *C. A.* 32, 4108[9]), and is cut by veins of nephelite-pegmatite. The pyroxenite resembles jacupirangite and consists of diposide-hedenbergite (n_α 1.695, n_γ 1.721), augite, acmite, magnetite and calcite. One of the alkali pegmatites is composed of nephelite, pyroxene, titanomagnetite, calcite and apatite. The calcite in these rocks is of magmatic origin, and represents the hydrothermal phase of the magma. It is suggested that the pyroxenite and olivinite were formed from an ultrabasic magma which has assimilated carbonate rocks, while the nephelite rocks represent the original magma. Several complete analyses.
C. A. Silberrad

Desert polish and sunburn of deserts and fossil deserts. J. Sioma. *Sprawozdanie Komisji Fizjograficznej Polskiej Akad. Umiejętności* 71, 165–79(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1938, 316.—S. does not consider that desert polish, etc., necessarily prove the former existence of desert conditions but that this formation resembles the hard pan resulting from an Fe-, Mn- or Ba-contg. formation in the subsoil that is now on the surface through erosion or denudation. Such formations with wad or psilomelane occur at many places in the Lysogóry hills of Poland. 25 analyses support this theory.
C. A. Silberrad

Petrography of sandstones of Zurawno. Włodzimierz Wawryk. *Arch. Mineralogiczne* 14, 75–105(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, 1938, 673–4.—These sandstones, some 70 m. thick, extend over an area 20 × 9 km., and are divided into loose, slightly compact, compact and very compact portions. They consist of varying proportions of glauconite, limonite and chalcedony, the compactness being due to cementation by calcite or silica. In places there occur inclusions of ilmenite, magnetite, zircon, rutile, tourmaline, staurolite, kyanite, etc. 19 complete analyses.
C. A. Silberrad

Iron sulfide impregnations in Finnish slate rocks. H. Hausen. *Tek. Fören. Finland Förh.* 59, 267–74(1939).—A brief résumé is given of Fe sulfide impregnations in the Finnish slate rocks. Pyrrhotite is widely distributed, and contains no Ni or noble metals. Pyrite is less widely distributed, but is occasionally found in beds of workable ore. Geophysical prospecting gives misleading results, for the deposits are often technically worthless.
H. C. Duus

The geochemical and geological factors of the formation of crude oil under the conditions existing in the Dnepr-Donets incline. V. B. Porfir'ev. *Trudy Neftyanoĭ Konf. Kiev* 1938; *Akad. Nauk U. S. S. R. (Inst. Geol. Nauk)* 1939, 149–161.—Various theories of oil formation are discussed. Nineteen references.
A. A. Boehtlingk

New data on the chemistry of waters beneath the Dnepr-Don depression and their connection with the size of the oil deposits. K. I. Makov. *Trudy Neftyanoĭ Konf. Kiev* 1938; *Akad. Nauk U. S. S. R. (Inst. Geol. Nauk)* 1939, 233–42.—A detailed analysis is given of waters from 20 different locations.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, OSCAR E. HARDER AND RICHARD RIMBACH

Some new metals. G. Stafford Whitby. *Can. Mining Met. Bull.* No. 333, 56–64(1940).—A general discussion of extn. and uses of Mg, ionium, polonium, U, Se, Te, Ti, Ta, Cb, Be, Li, In, etc.
Alden H. Emery

Metal production figures for 1939. United States Bureau of Mines. *Mining J.* (Phoenix, Ariz.) 23, No. 17, 5–11, 38–48(1940).—A survey covering Alaska, Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, South Dakota, Texas, Utah, Washington and Wyoming.
Leopold Scheflan

Wetting in flotation. H. Freundlich. *Wetting and Detergency Symposium*, Feb. 19–20, 1937, *Brit. Sect. Intern. Soc. Leather Trades' Chem.* 1–10.—A review with 39 references. **Wetting metals by metals with particular reference to tinning and soldering.** E. J. Daniels and D. J. MacNaughtan. *Ibid.* 77–84.—See *C. A.* 32, 2494[1].
M. M. Piskur

Lime in base-metal flotation. E. H. Rose. *Trans. Can. Inst. Mining Met.* 42 (in *Can. Mining Met. Bull.* No. 331), 533–6(1939).
Alden H. Emery

The frothing power of various frothers in flotation. Zyoitiro Hunakosi. *Suiyokwai-Shi* 10, 113–19(1939).—From expts. on the flotation of pyrites H. finds that the frothing quality is proportional to the max. height of the froth layer.
Hideo Nishimura

Mineral dressing. A. H. Fahrenwald. *Eng. Mining J.* 141, 80–3, 91(1940).—There is increased application of the sink-and-float process. New flotation agents have been studied and improvements made in crushers and screens. Overgrinding is greatly lessened, mineral recovery improved and increased economy effected by use in the ball-mill-classifier circuit of mineral-recovery devices and processes such as (1) amalgamation, (2) the flotation cell, (3) corduroy strake and (4) the jig. **Iron-ore beneficiation.** Joseph Rudolph. *Ibid.* 83, 84.—Heavy-medium concn. is applied in new com. scale plant on the Mesabi. The possibilities of low-grade ores and the flotation of fine tailings are discussed.
W. H. B.

The Vaucluse gold mine, Orange County, Va. Charles E. Bass. *Econ. Geol.* 35, 79–91(1940).—The Au is assocd. with pyrite, quartz and ankerite along a shear zone in a quartz-sericite-chlorite schist. Data are given on mining production and costs from 1935 to 1938, when the mine closed.
Michael Fleischer

Operations at the Old Eureka mine. L. A. Norman, Jr. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. 1136, 15 pp.(1939).—The ore for 1938–39 averaged 0.62 oz. Au per ton. It is treated in a stamp mill, then in one of the few remaining installations of successfully operating vanner tables, followed by flotation and cyanidation to reduce losses. Recovery in the stamp mill was 90.37%, total recovery, 97.17%. Costs were $16.090 per ton.
Alden H. Emery

Gold-antimony deposits of Nullagine. M. R. McKeown. *Chem. Eng. Mining Rev.* 32, 143–4(1940).—Auriferous conglomerate deposits are best known and good recovery has been effected by cyanidation. Oxidized ore has been successfully treated on the mine by cyanidation, and flotation for concn. of the Sb followed by cyanidation

of the flotation tailings has given recoveries of 85% of the Sb and 95% of the Au. W. H. Boynton

Results of researches on aluminum in Poland. Jan Czochralski. *Aluminum and Non-Ferrous Rev.* **4**, 333 (1939).—A review. Iver Igelsrud

Aluminum and its applications. James W. Cameron. *Can. Mining Met. Bull.* No. **330**, 445–64(1939).—A review. Alden H. Emery

The separation of aluminum from scrap metals. C. C. Downie. *Aluminum and Non-Ferrous Rev.* **4**, 318–19 (1939).—Scrap Al mixed with heavy metal scrap is charged into a soln. of salts of the alkalies, alk. earths, or other metals baser than Al and of a sp. gr. greater than Al. The Al floats and is sepd. Iver Igelsrud

Copper metallurgy. W. B. Boggs. *Eng. Mining J.* **141**, 87–8(1940); cf. *C. A.* **33**, 2857[1].—Differences in smelter practice in the Southwest and in Canada are noted. Noranda uses slag and tailings for stope filling underground. **Lead metallurgy.** G. L. Oldright. *Ibid.* 89, 94; cf. *C. A.* **33**, 2857[6].—A review for 1939. Sintering in connection with blast-furnace operations, S recovery, rough-drossing and Pb-alloy production are discussed. **Zinc metallurgy.** S. M. Shelton and H. R. Hanley. *Ibid.* 90–1; cf. *C. A.* **33**, 2859[6]. **The uncommon metals.** R. S. Dean and V. H. Gottschalk. *Ibid.* 92–3.—La is prepd. by electrolyzing its fused chloride. Its use for hardening Al and Mg alloys has been suggested. Other metals reviewed include Mn, Ti, Zr, Mg, Ba, Ca, Cb, Ta, Cr, B, Cd, Ga, In, Sb, Bi, Mo, Se, Te and As. W. H. Boynton

A complex process for treating iron ore containing phosphorus and phosphorite. A. M. Malets. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 10, 27–30(1939); cf. *C. A.* **33**, 4560[6].—Ore contg. Fe and P is heated with C in a hearth furnace at 1300–1500°. Fe_2P is formed and drawn off as a liquid. The gases from the reaction contain 32–5% CO and can be used for *fuel*. The Fe_2P is treated at 1200–1500° with CaO and Fe_2O_3 and gives Fe suitable for making steel. The phosphate slag can be ground and used for *fertilizer*. Almost all its P_2O_5 is citrate-sol. In the starting ore, the Fe : P ratio should be 3:1, the ratio of Ca:Si should be 1.1–1.3 and there should be less than 2% S. Since no one ore fulfils these conditions, it is necessary to produce the proper compn. by mixing various ores. H. M. Leicester

Comparative values of iron ore at the blast furnace. George W. Hewitt. *Blast Furnace Steel Plant* **27**, 1231–7 (1939); **28**, 50–2, 70(1940). C. B. Jenni

The nickel industry in 1939. Wider applications in non-ferrous alloys. Robert C. Stanley. *Metal Ind.* (London) **56**, 107–10(1940); cf. *C. A.* **33**, 7705[5]. E. H.

Nickel industry in Urals. B. Bogitch. *Rev. mét.* **36**, 421–8(1939); cf. *C. A.* **34**, 349[1].—Three main deposits of Ni ores are known, Khalilov, Akermanovka and Actuba, all of them characterized by a Ni content of about 2%, though the total content of the metal is estd. as several hundred thousand tons. Only open-pit mining is used, and the ores melted without any dressing. Only one modern plant at Orsk is in operation; 2 others melting the ore are very small and obsolete. The ore is sintered, fluxed to take care of excessive gang content and melted for mat in 1.60 × 13.4 m. water-jacketed furnaces. Low Ni content is taken care of by slow descent of the charge and prevention of fine accumulation in the center of furnaces. About 0.25% Ni is lost in slag and 350 kg./ton of coke used, producing mat with 30% Ni, 20% S and 50% Fe. It is purified in 5–10-ton magnesite-lined convertors. J. D. Gat

Uses and metallurgy of ferrous scrap metals. M. W. Von Bernewitz. *Blast Furnace Steel Plant* **27**, 1226–30 (1939).—Importance of scrap as a commodity and its use in metallurgical processes are discussed. C. B. J.

Bessemer blowing with constant pressure at the wind box. Sherman Chase. *Blast Furnace Steel Plant* **27**, 1029–32(1939).—Improvements to blowing equipment, bottom design and tuyère design can be made only when the process of Bessemer blowing is more thoroughly understood. The effect of stalagmitic growths on tuyères has either been ignored or misinterpreted. Math. analysis is presented for the process. C. B. Jenni

Sprung-arch roofs of high-temperature furnaces. J. Spotts McDowell. *Blast Furnace Steel Plant* **27**, 592–7, 947–51(1939); **28**, 161–8, 178(1940).—Properties of available refractories including silica brick, alumina-silica brick, magnesite brick, chrome brick, chrome-magnesite brick and forsterite brick are fully discussed. Details of arch construction and the mechanics of high-temp. arches are discussed. C. B. Jenni

Comments on Southern blast furnace practice and some of its peculiarities. J. E. Urquhart. *Iron Steel Engr.* **16**, No. 9, 72–80(1939).—Proximity of iron ore, limestone and coal deposits and mild climatic conditions make it unnecessary to build up large inventories of stocks. Because of lean ore, slag vols. average 2000 lb. per ton and coke consumption is increased. Potential value of ore prepn. has not been realized until recently. Research program on red ore had 3 objectives: improvement of pig-iron quality, more efficient furnace practice, and elimination of furnace irregularities prevalent in southern practice. Tests showed that there was no appreciable swelling of the ore; calcination of the calcite component began slightly under 1100°F. and temp. of completion of reaction was governed by size of pieces and pressure in the furnace; size of ore particles has little effect in its degree of reducibility at 2200°F. but a marked effect at 1700°F.; the slight reduction that took place between 1100° and 1600°F. was probably due to the calcination of the $CaCO_3$ component so that the liberation of CO_2 retarded the contact between the Fe oxides and the CO; the CO_2 liberated on calcination of the calcite in the ore is of little value and is probably a detriment to the coke efficiency, since it is liberated at temps. high enough to react with the coke to form CO, which when formed is so high in the furnace that it has little opportunity to reduce the basic ore. Coals used for coking all require washing, but little work has been done on pulverizing the coal. Sizing of coke has not been followed with the exception of breeze removal. Furnace design and operation, effects of humidity, flue-dust disposal, slag utilization, and gas cleaning are discussed. C. B. Jenni

Effect of the solution-loss reactions on blast-furnace efficiency. P. V. Martin. *Blast Furnace Steel Plant* **27**, 669–73, 1039–42, 1126–31(1939).—See *C. A.* **33**, 9226[6]. C. B. Jenni

Refining of metal in the basic open-hearth furnace. W. B. Lawrie. *Blast Furnace Steel Plant* **27**, 675–9, 943–6, 1043–5(1939); cf. *C. A.* **33**, 6206[2].—The chemistry of refining in the basic open-hearth furnace is developed. The influence of fluorspar on the slag, the action of Mn in the removal of S, the effect of FeO, the behavior of Cr, Ni, P, C and iron oxides are all discussed. Twenty-three references. C. B. Jenni

Physical and chemical properties of stoppers in open-hearth service. Joseph A. Sarandria. *Blast Furnace Steel Plant* **27**, 1133–6(1939).—Resistance to abrasion or erosion must be high in stopper heads. Porosity and water absorption affects the resistance to spalling and the possible penetration of the metal. The P. C. E. or softening point must be high enough to stand steel temps., so that there is a min. amt. of fusion reaction with the nozzle. The cold-fired strength should be sufficient to withstand the assemblying where the stress is concd. on the bolt hole and shoulder. The load-bearing capacity should be high at steel temps., because the stopper must resist the pressure of the ferrostatic head of the metal and the manual pressure exerted in making the shut-off. The thermal cond. properties must produce a definite temp. gradient. Data are given on chem. compn. and phys. properties of various stopper heads. C. B. Jenni

The manufacture of rimming steel at Briton Ferry. J. S. Lewis. *Engineering* **148**, 687(1939); cf. following abstr.—The cold-pig iron and scrap process, in the open-hearth furnace, is used. About 40% pig iron and cast iron and 60% high-grade scrap with enough lime or limestone (10–12% limestone) to make a good slag are employed. The steel should contain about 0.3% C when

clear. Ore or scale is then added until the C is down to 0.14–0.16%. Enough oxide should then be present to bring it down to 0.08% or less. Prior to tapping the bath analysis should be C under 0.08, P under 0.04, S under 0.05 and Mn under 0.15–0.18%. Low casting temp. aids the rimming properties. The best ladle addns. for deoxidation are Al and ferromanganese. About 3–5 oz. of Al per ton is necessary. To secure the best rimming action the Mn content is brought to 0.32–0.36% by adding about 8 lb. of ferromanganese (80% Mn) per ton of steel. The best even rim is obtained with large molds with a ratio of length to cross section less than 4:1. The molds should not be hotter than hand warm and should be coated with dehydrated tar. Small nozzles are best. The pouring rate by this method is about 1 ton per nozzle per min. A flat rim with inappreciable rise or fall during the rimming action is obtained. Iver Igelsrud

Rimming steel from open-hearth furnaces. J. S. Lewis and R. S. Rolfe. *Blast Furnace Steel Plant* **27**, 1223–5(1939); cf. preceding abstr.—Practice as carried out at Briton Ferry and at Bilston, England, are described. C. B. Jenni

Practical aspects of steel making. C. L. Altenburger. *Iron Steel Engr.* **16**, No. 12, 11–21(1939).—Influence of size and quality of scrap is emphasized. The greater the Si content of the charge, the greater will be the C at meltdown. When bath Si is very low or the proportion of total scrap which is light is high, the heat will melt soft. Residual Mn in the bath depends on the ratio of FeO to MnO in the slag and on temp. Variation in the nature of fuel used is discussed. The cleaning of the furnace after a heat is stressed. Slag characteristics and slag control are briefly considered. C. B. Jenni

Steel plant at Corby. M. T. Colclough and R. P. Lemoine. *Rev. mét.* **36**, 326–34(1939).—One of the latest developments of British steel metallurgy is the Corby plant operating on ores low in Fe and high in P. The article describes, in general, the plant and equipment used at the plant together with metallurgical peculiarities of the ore prepn., smelting and steel-making processes. J. D. Gat

Macroscopic structure of steel ingots. Luigi Bruno. *Rev. mét.* **36**, 335–54(1939).—An extensive investigation covering the nature and distribution of blowholes and pipe in ingots made in open-hearth and arc furnaces. It developed from the successful attempts to make *open steel* having a good surface with 0.30% or more C in basic elec. and open-hearth furnaces. The steel of the desired type could be produced with C reaching up to 0.40% without any rising in the molds, particularly when somewhat reducing slags were used. The usual slags cause an excessive gas evolution. *Recovery of C, Mn and Si in open steels* of the type described is given. The mechanism of blowhole formation is explained along the generally accepted lines for killed, semikilled and wide-open steels. J. D. Gat

Greases in every steel mill. Harry D. Kolb. *Blast Furnace Steel Plant* **27**, 939–42(1939).—Classification and properties of greases are discussed. Recommended greases for specific applications in steel equipment are given. C. B. Jenni

Recent investigations on the viscosity of liquid metals and alloys. W. Claus and F. Blank. *Metallwirtschaft* **18**, 917–24, 938–43(1939). G. G.

Nature and kinetics of growth of the intermetallic phases produced in the course of interdiffusion of metals. V. S. Bugakov and D. Ya. Gluskin. *J. Tech. Phys.* (U. S. S. R.) **9**, 1293–1301(1939); cf. *C. A.* **30**, 7952[8].—At the boundary between Cu and Cd above 400° the compd. $CuCd_3$, and below 400° also a narrow layer of Cu_2Cd_3, is formed. Ag and Zn at 400–450° give AgZn, Ag_3Zn_8 and $AgZn_3$. Ag and Cd produce AgCd and Ag_5Cd_8. Apparently the formation of phases having high heats of formation is favored. The thickness of the diffusion layer increases linearly with the square root of time. The rate of its growth is given for various phases and temps. Micro-sections and x-ray patterns were used. J. J. B.

Residual tensions produced by bending. N. N. Davidenkov and E. M. Shevandin. *J. Tech. Phys.* (U. S. S. R.) **9**, 1112–24(1939).—Expts. on a Cr-Mo steel are reported. J. J. Bikerman

Salt-bath quenching. Saburo Abe. *Tetsu-to-Hagane* **25**, 1065–73(1939).—Steel heated above the critical point and quenched in a salt bath at a temp. between 180° and 400° until it is completely transformed is tougher at a high hardness than the same steel quenched in oil and tempered to the same hardness. This treatment is very effective for C steels of about 0.7–0.9% C, Cr steels of about 0.7% C, Ni-Cr steels and Ni-Cr-Mo steels of 0.3% C. It is not effective for Ni steels of about 0.7% C, Ni-Cr steels and Ni-Cr-Mo steels of about 0.7% C. Davenport and Bain attribute to the presence of micro cracks in the oil-quenched pieces their inferior toughness. In the present expts. no cracks were found in the oil-quenched alloy steels. A. believes the superior toughness of the salt-bath quenched samples is due to the microstructure, which is different from that of steel quenched into oil, and also to the lower stress of transformation. M. Ishida

Metal coloring theory and practice. Joseph B. Kushner. *Products Finishing* **4**, No. 5, 32–4, 36, 38(1940).—Detailed directions are given for producing yellow, red, rose, green, antique and white shades of Au; sp. formulas are shown. Suitable heat treatment is discussed. Leopold Scheflan

Wear and tear in rolling and sliding friction. Anton Eichinger. *Eidgenoss. Materialprüfungs- u. Versuchsanstalt Ind., Bauw. Gewerbe, Zurich*, Diskussionsber. No. **121**, 32 pp.(1938).—Expts. on the wear and tear incurred in rolling and sliding friction led to a classification of such wear and tear under 3 heads: (1) Mech., leading to deformation of the material and subsequent fatigue affecting the marginal layer. Remedies are choice of the proper material, cooling and lubrication. (2) Electromagnetic. There is no wholly effective remedy, but the effect is less serious since the surface remains smooth and is even improved in quality. (3) Technologic-chemical, in the case of dry friction or insufficient removal of the generated heat. It leads to the formation of surface oxidation or nitration layers. This is not an unmixed evil, since such layers offer resistance to wear and tear. Combinations of the 3 classes increase the difficulty of the practical problem of wear and tear and require careful analysis of each individual case. A. H. Krappe

Role of metals in deep-well drilling. W. L. Nelson. *Oil Gas J.* **38**, No. 29, 37, 52(1939).—The metallurgy of steels required under the extreme conditions of modern deep wells. W. Andrew Wright

Metals in drilling. IX. Drilling string and casing. W. L. Nelson. *Oil Gas J.* **38**, No. 29, 69(1939); cf. *C. A.* **34**, 1285[1] and preceding abstr.—The metallurgy of steels used for drilling strings and casings. **X. Miscellaneous alloy equipment.** *Ibid.* No. 31, 53. W. Andrew Wright

Metallographic grinding with abrasives fixed in lead disks. Kurt Amberg. *Metal Progress* **37**, 146–9(1940); cf. *C. A.* **32**, 1062[3]. W. A. Mudge

Brittleness of polycrystalline solid solutions containing α-iron or magnesium as base. Ya. B. Fridman and M. S. Denisova. *J. Tech. Phys.* (U. S. S. R.) **9**, 1465–77 (1939).—The reduction of the cross section of a bar under tension was detd. as a function of the real tension. It was less for Fe + 3% or 5% of Ni than for Fe. The real tensile strength increases on addn. of Ni at −195° more than at 20°. The brittleness of Mg is lowered by 3–5% of Al but its real tensile strength remains almost unaffected. J. J. Bikerman

Recrystallization texture of aluminum after compression. Charles S. Barrett. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. **1141**, 18 pp. (1940).—Results of this study invalidate or require modification of several theories of recrystn. textures of Al, notably those relying on Taylor's "local distortion," those attributing the retention of the polycryst. texture to a retention of orientation in individual areas, and those proposing a twinning mechanism in recrystn. C. L. M.

Correlation of deformation and recrystallization textures of rolled 70–30 brass. R. M. Brick. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. 1144, 20 pp.(1940).—Results of an x-ray analysis of the deformation texture of heavily rolled, polycryst. 70:30 brass are given. The influence of the reductions and anneals prior to final rolling were studied. C. L. Mantell

Plastic deformation and recrystallization of aluminum single crystals. J. A. Collins and C. H. Mathewson. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. 1145, 17 pp.(1940).—Strain-annealing expts. are reported on a wide variety of orientations covering nearly the entire range of slip on a single system and corresponding to amts. of shear (ratio of shearing distance to distance between lamellae) at the conclusion of a test of from 0.08 to 0.57. C. L. Mantell

Tensile deformation of critically oriented brass crystals. H. L. Burghoff. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. 1149, 8 pp.(1940).—Deformation of 4 single-crystal specimens of 70:30 α-brass, critically oriented, provided a demonstration of the applicability of the max. resolved shear stress law with deformation possible on different slip systems in adjacent regions of a crystal at the same time. C. L. Mantell

Variation of internal friction with grain size. Clarence Zener and R. H. Randall. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. 1146, 7 pp. (1940).—An investigation of the precise manner in which the internal friction due to thermal currents flowing back and forth between adjacent grains varies with grain size. C. L. Mantell

The reaction conditions in refining aluminum with cryolite and sodium fluosilicate. L. Tronstad and J. H. Reimers. *Aluminium* 21, 834–8(1939).—In remelting Al, the oxide films formed on the surface and as suspensions in the melt must be removed before pouring, to ensure a sound product free of inclusions and pores and of good mech. properties and corrosion resistance. In small furnaces blowing N or Cl through the melt is a reliable method for the removal. In large melting and remelting furnaces the refining agent is added either to the solid charge (for this purpose cryolite is particularly suitable) or to the melt (in this case Na_2SiF_6 is preferable). In the system Al_2O_3–Na_3AlF_6 no Al_2O_3 is absorbed below the transformation point of the Na_3AlF_6; beginning at 650°, the absorption starts and increases with increasing temp. Cooling to below the transformation point ppts. the absorbed Al_2O_3 in submicroscopic form. Na_2SiF_6 dissociates on heating, the dissocn. pressure of SiF_4 reaching 760 mm. at 716°. The NaF formed melts only at 1000°. While the chem. reactions between Al_2O_3 and Na_3AlF_6 take place in the solid state, melting occurs in Na_2SiF_6 only above 690°, owing to formation of polyeutectic systems. Al_2O_3 is not absorbed in the crystal lattice below 680°. The absorption of Al_2O_3 by Na_2SiF_6 is due to formation of Na_3AlF_6 and SiO_2 (probably in solid soln.) and of SiF_4, which loosens the oxide films. α-Al_2O_3 is less reactive than γ-Al_2O_3. Nine references. M. Hartenheim

Copper and copper alloys. Their properties and applications. H. W. Brownsdon. *Trans. Inst. Marine Engrs.* 51, 277–89(1939).—A discussion with 8 micrographs, 10 graphs and 53 references. Ann Nicholson Hird

The boiling point of magnesium and magnesium alloys. Armin Schneider and Udo Esch. *Z. Elektrochem.* 45, 888–93(1939).—A simple, ebullioscopic method for the detn. of the b. p. of Mg and Mg alloys is described. The value 1103 ± 5° for the b. p. of Mg is in good agreement with the best literature values. Exptl. results for Mg alloys with Al, Ag, Cu, Sn and Pb up to 40 atomic % show that at temps. in the vicinity of the Mg b. p. the meltings should be regarded as "ideal concd. mixts." M. McMahon

Nickel; engineering application of the metal and its alloys. K. H. J. Clarke. *Can. Metals Met. Inds.* 3, 12–14(1940).—The uses of Ni and Ni alloys are classed in 3 groups: ferrous alloys, nonferrous alloys, and pure Ni. A survey shows that 65% of Ni entering world industry is in steel, cast iron or high Ni-Fe alloys. Ni strengthens, toughens and hardens the ferrite without loss of ductility and it lowers the crit. temps. and slows down the rate of transportation of austenite into the other forms. The use of lower quenching temps. necessary for heat treatment results in finer grain with improved elastic properties, impact resistance and toughness; it reduces fuel costs and equipment wear. Special uses are noted for low-alloy steels, corrosion and heat-resisting steels, cast irons, special alloys of the Invar and Permalloy types, nonferrous Ni alloys and pure Ni. W. H. Boynton

Melting practice, structure and mechanical properties of gray cast iron. P. Bardenheuer. *Giesserei* 26, 543–49, 564–6(1939).—The most essential characteristics for high-grade cast iron are: finest distribution of graphite, and pure pearlitic matrix. Ferrite is formed only under abnormal cooling conditions. Other forms of matrix such as sorbite, martensite, etc., can be obtained by suitable treatment. The most unfavorable condition exists when crystn. of the graphite eutectic takes place after undercooling; this occurs when no nuclei are present to initiate crystn. Too high melting temp. has this effect. This may be offset by ladle addn. of ferrosilicon or ferromanganese. Low-Cr, high-Si contents and also elevated P and S percentages counteract undercooling. Addns. of Ca silicide and similar compds. have the same effect. Moreover, the formation of the pseudo-eutectic can be avoided by suitable selection of the slag (rich in ferrous oxide). Dissolved gases can act as nuclei. Melting in the cupola has the advantage that in the production of high-grade low-C alloys the iron is not overheated; enough nuclei are preserved to take care of graphite pptn. Only in very few cases (thin sections) addns. of ferrosilicon or similar materials are required. On the other hand, melting in the reverberatory furnace is rather slow. The formation of artificial nuclei by ladle addns. to alloys with less than 3.4% C is recommended. A method to produce high-grade cast iron in the reverberatory furnace is: using malleable as raw material, placing a definite amt. of ferrosilicon on the bottom of the crucible; pouring the iron with simultaneous spraying of powd. ferromanganese. Another method is melting the iron from an inferior charge and alloying it in the furnace. The elec. furnace and high-frequency furnace are similar in their effect. The danger of overheating is greater. They allow thorough removal of S and P. The process is economical only under certain conditions. In most cases the elec. furnace is used for subsequent desulfurization. High-frequency furnaces act like arc furnaces. The same addns. are required to offset overheating. The advantage of chill casting with subsequent annealing is demonstrated. As in malleable casting it is essential that the metal solidify as white iron. The compn. was: C 2.62, Si 2.10 and Mn 1.3%. Hypereutectic alloys with high Si content show, when sand-cast, coarse graphite lamellae with agglomerated ferrite; they have good strength properties. Annealed chill castings of this type have only ferrite in the matrix; they have good strength but poor deflection and repeated-impact properties. R. P. S.

Desulfurization of pig iron with calcium carbide. C. E. Wood, E. P. Barrett and W. F. Holbrook. *Am. Inst. Mining Met. Engrs., Tech. Pub.* No. 1131, 15 pp. (1939).—Metal contg. 0.01% or less of S can be produced by use of CaC_2 at a cost that does not appear to be excessive for this type of metal. Desulfurization with carbide offers some advantages over use of alkalies in the production of metal with extremely low S; as S approaches 0.02%, the efficiency of alkalies decreases rapidly, while carbide continues to be effective. Methods for adding carbide to the melt are described. Alden H. Emery

Rapid dephosphorization of steel by a solid flux. Paul Girod. *J. four élec.* 48, 97–8(1939).—P in Thomas elec. steel can be reduced to 0.02% by placing 1.7% by wt. of the steel of a patented mixt. of iron oxide, lime fluxing agent and activating agent in the ladle before the molten steel is added. Ladle preheat should be to 500° to 600°. If P must be reduced to 0.015% the dephosphorizer is spread on the hearth of the finishing furnace, then the metal is poured in. C. F. Bonilla

Influence of the treatment of the surface of the notch on the cold brittleness of steel specimens. E. M. Shevandin. *J. Tech. Phys.* (U. S. S. R.) **9**, 1103–11(1939).—The crit. interval of brittleness is not affected by the state of the surface of the notch (whether made by file or chisel, whether etched by HNO_3 or not, etc.). The sudden transition on a lowering of the temp. from partly brittle to wholly brittle fractures of notched specimens is produced by fissures along the boundaries of grains. Specimens with many indentations show a narrower crit. interval than those with one notch. J. J. Bikerman

Relation between the critical temperature of cold brittleness and the rate of deformation. N. N. Davidenkov. *J. Tech. Phys.* (U. S. S. R.) **9**, 1051–62(1939).—A material becomes brittle at the temp. at which its yield value exceeds its brittleness value; the latter is independent of temp. The theories of Becker (*C. A.* **21**, 1385) and Prandtl (*Z. angew. Math. Mech.* **85**(1928)) 3 connecting the yield value with temp. and rate of deformation v give similar relations between the crit. temp. and v for intact specimens, but different expressions for notched specimens. Study of notched samples has, therefore, a special importance. J. J. Bikerman

New device for studying the cold brittleness of steel at high velocities of impact. F. F. Vitman. *J. Tech. Phys.* (U. S. S. R.) **9**, 1063–9(1939).—A knife (or a double 4 knife for notched samples) is fixed to a wheel which can be rotated at various speeds so as to change the rate of impact of the knife on the specimen. The deformation of notched steel at which a fracture takes place decreases when the rate of impact increases; at the rate of 50 m./sec. the deformation became zero (i. e., the specimen became brittle). J. J. Bikerman

Influence of the rate of deformation on the cold brittleness of steel. I. F. F. Vitman and V. A. Stepanov. 5 *J. Tech. Phys.* (U. S. S. R.) **9**, 1070–85(1939); cf. preceding abstr. The crit. temp. of brittleness of steel cylinders (0.2% of C, av. grain size 53 μ) was at the rates v of impact of 6×10^{-4} and 83 m./sec., resp., −165 and −75° (ground cylinders) and −155 and −45° (rolled cylinders), resp. Some ground cylinders were bent; the pressure at the yield point increased from 50 kg./sq. mm. at 13° to 112 kg./sq. mm. at −170°. This pressure $p = ae^{b/t}$, t being the temp. and a and b consts. If the brittleness value is independent of the rate of impact, the relation between p and v can be found; p increases by 60% 6 when v increases 10^4 fold. 44 references. J. J. B.

Critical temperature of brittleness. T. A. Kontorova. *J. Tech. Phys.* (U. S. S. R.) **9**, 1086–9(1939).—In the relation between the rate v of impact and the crit. temp. T of brittleness (cf. Vitman and Stepanov, preceding abstr.), $v = v_0 e^{-U/kT}$, v_0 has the meaning of the ratio of the 7 breaking strength to the viscosity of the material, and U is the activation energy for transition of an atom from one to another position of equil. From Vitman and Stepanov's results U is 5200 cal./mol. J. J. Bikerman

Simplified method of determination of the critical temperature of impact brittleness. N. N. Davidenkov, N. A. Zlatin and E. M. Shevandin. *J. Tech. Phys.* (U. S. S. R.) 9, 1090–102(1939).—Notches cut on the opposite ends 8 of a horizintal diam. are broken by a wt. hitting from above, and their deformation assocd. with rupture is measured at various temps. This deformation decreases on lowering of temp. and becomes zero at the lower boundary of the "crit. interval." The position of this boundary strongly depends on the size of the ring, the depth of the indentation, etc.; but keeping all these dimensions const. it is possible to compare various steels and to obtain for them a correct order of brittleness. J. J. Bikerman

Optical method of determining the texture of transformer steel. E. S. Yakovleva. *J. Tech. Phys.* (U. S. S. R.) **9**, 1280–5(1939).—Light reflection from electrolytically etched surfaces allows detn. of the orientation of grains in metals. A steel (3.6% of Si) with grains between 5 and 0.5 mm. had, e. g., 37% of grain (cube) edges in the direction of rolling ±10°; 54% of the cube faces were inclined to the rolling plane under the angles of 30–42°. J. J. Bikerman

Steels for high-temperature service and their testing. A. E. White. *Am. Soc. Testing Materials, Bull.* No. **100**, 15–20(1939).—Methods and evaluation of short-time high-temp. tests, tension-creep tests, stress-rupture tests and surface-stability tests are briefly reviewed. L. Pessel

Austenite grain size of carbon steel. Sitiro Yanagisawa and Masaki Yamasita. *Tetsu-to-Hagane* **25**, 1027–34 (1939).—Test pieces were taken from 20 sheets of high-C steels with about the same chem. compn. which were made in both the acid and the basic open-hearth furnace. In the normalized condition, 2 kinds of test pieces showed the same results with respect to the tensile test, but in Charpy's impact test, the basic steel is inferior and the impact value depends on the coarseness and fineness of austenite grains. Further expts. were made with the McQuaid-Ehn test and it was proved that the grain size detd. by this method indicates the inherent nature of steel and that the steels having the same grain size show about the same phys. properties regardless of the kind of steel-refining furnace used. The result of the test with reference to the change of austenite grain size in the process of refining discloses that the control of grain size is necessary for the improvement of the quality of steel. M. Ishida

Austenitic manganese steels; development, structure, heat treatment; use of 10–14% manganese in these steels. J. A. De Bondy. *Can. Metals Met. Inds.* **2**, 279–81(1939).—A review. Leopold Pessel

Forms of nitrogen in chromium, nickel-chromium and nickel-chromium-molybdenum steels. Isao Hayasi and Masaru Ebisuda. *Tetsu-to-Hagane* **25**, 1035–42(1939).—Percentage of N was detd. in both HCl soln. of the steel and in the HCl-insol. residue. In the quenched state, most of the N will be dissolved in austenite or martensite of Cr, Ni-Cr and Ni-Cr-Mo steels. Tempering at high temps. will cause most of the N to sep. as $(Fe, Cr, N)_3C$, i. e., almost all N atoms will be dissolved in the space lattice of Fe_3C with Cr atoms. Ni and Mo have no effect on the N sepn. When Al in these steels exceeds 0.05%, the phenomenon will suddenly disappear. Ti will fix about 93% of the N in liquid steel as nitride when 0.7% of the Ti exists in these steels in a form that is soluble in HCl. M. Ishida

Nickel-containing permanent-magnet steels. Masaru Yamaguti. *Japan Nickel Inform. Bur., Tech. Inform.* **B-13**, 91 pp.(1939). E. H.

Determination of silicate inclusions in steel. Sasaburo Kobayasi Yosikazu Kanamori and Kasuzo Kosiya. *Tetsu-to-Hagane* **25**, 1074–80(1939).—In the detn. of silicate inclusion in steel, by Dickenson's nitric acid process (*C. A.* **20**, 2643), considerable time is taken for dissolving samples and the manipulation is comparatively tedious. In a suggested modification, samples weighing about 100 g. are treated in HNO_3 (1:3) at about 90° for 30–40 min., and the excess acid is neutralized with NH_4OH. The residual silicate inclusion is treated with $KMnO_4$ soln. and H_2O_2 as in Dickenson's process. By this rapid process, one complete analysis can be finished within only three days, and the result is sufficiently reliable. Sisco's electrolytic method (cf. *C. A.* **22**, 2718) is recommended for detn. of silicate inclusion in 18/8 steel or other high-Cr steels, which are difficult to dissolve in HNO_3. M. Ishida

A study on extruded rods of aluminum alloys. Masahide Kosaki and Hyōzi Nakata. *Nippon Kinzoku Gakkai-Si* **3**, 449–60(1939).—Excellent mechanical properties of extruded duralumin and superduralumin metals 9 are attributed to a peculiar microstructure due to extrusion. Hideo Nishimura

Effect of various additions on the crystallization of eutectic aluminum-silicon alloys. G. Gürtler and E. Schulz. *Giesserei* **26**, 537–43(1939).—The addn. of Na shifts the f. ps. of the Al-Si eutectic to a lower temp. and higher Si concn. If excessive amts. of Na are added, bands form; their appearance indicates that there may be a ternary eutectic. Strength and ductility are increased by this

refinement. Excessive Na is to be avoided on account of 1
the tendency to formation of oxide skin and foam inclusion. The properly refined alloy contains the unavoidable Fe in the form of tetragonal Al_4Si_2Fe. If over-refined or insufficiently refined (to a certain degree) these crystals do not form in the ternary eutectic but they form as coarse primarily solidified crystals. This effect can be offset by adding about 0.3% Mn; this transforms the lamellae into conglomerations, mostly dendritic; in this 2
form they are practically harmless. Addn. of 0.3 to 0.4% Co has a similar effect. If the customary 0.4% Mg is added (Mn also being present) solidification from the melt takes place as follows: primary Al crystals, binary eutectic Mg_2Si, ternary eutectic Al-Si-Mg_2-Si. In the ternary veins further Fe- and Mn-bearing crystals occur whose compn. depends on the speed of solidification. The veins with ternary eutectic are of greater hardness than the other zones. This leads to difficulty in machining 3
although it does not impair the total strength of the casting. The most effective means for avoiding vein formation is rapid cooling; thus crystal segregation is avoided. Long homogenizing annealing also yields a more uniform structure. A further way to reduce the veins is a reduction in Si to about 10%. In the Mg-bearing alloy the refinement by Mn addn. is not as important as in the plain alloy. On the other hand, lack of Mn increases the tendency to shrink-hole formation. Cu addns. act in a 4
manner similar to Mn. The addn. of 0.3% Ti increases crystn. nuclei of the primary Al crystals. One % Zr has a similar effect, but has the advantage that the Zr-bearing crystals are dendritic, whereas the Ti-bearing crystals are brittle lamellae. The addn. of P has the opposite effect from Na: it brings about a finer distribution of the primary Si, while the eutectic is coarsened. For some applications, e. g., bearing surfaces, a structure with 5
evenly distributed hard crystals such as produced by P in a 21% Si alloy is of particular advantage.
Richard P. Seelig

Effect of titanium and iron on aluminum-silicon alloys. Hideo Nishimura and Eitaro Matumoto. *Suiyokwai-Shi* **10**, 105-12(1939).—Ti in less than 0.5% has practically no effect on the properties of Silumin, and the alloy is amenable to the usual modification by metallic sodium, but when there is also present with Ti about 6
0.5% of Fe the refining effect of Na is overcome by the growth of the ternary compound $Al_3Fe_2Si_2$; this produces a coarse, brittle material. Hideo Nishimura

An investigation of superduralumin (effect of iron). Hideo Nishimura. *Nippon Kinzoku Gakkai-Si* **3**, 420–4 (1939); cf. *C. A.* **33**, 953[7].—Increase of Fe in Al alloys contg. Mg and Cu suppressed age-hardening when they were quenched at room temp. or tempered at 50 150°. 7
From the investigation of the diagram of the Al Cu Fe system, and the irregular dilatation of quenched specimens on tempering, it was ascertained that the soly. of Cu in Al is decreased by the formation of a N compd. Similarly aging of Al-Cu-Mg alloys contg. Fe is somewhat suppressed by the decrease of solid-soly. and the formation of a N compd. Hideo Nishimura

Effect of chromium addition to magnesium alloys on the rate of corrosion. Susumu Morioka. *Nippon Kinzoku Gakkai-Si* **3**, 431–6(1939).—The addn. of Cr to Mg alloys contg. Al is as effective in reducing the rate of corrosion 8
in 0.1 *N* HCl as is the addn. of Mn, but in Mg alloys contg. both Al and Mn, Cr has little or no effect. All alloys thus prepd. contained only 0.01–0.03% Cr, irrespective of Cr content in mother alloys used and it is somewhat doubtful whether the beneficial effect is due to Cr. The effects of Sn, Cd, Pb, Ca, Sb, Ni, Si, Ce, Se, Ba, Mo, V or Zr added 9
to Electron AZG alloy contg. small amount of Cr were studied. Hideo Nishimura

Copper-base alloys containing 20% of iron. Masazō Okamoto. *Nippon Kinzoku Gakkai-Si* **3**, 437–43(1939).—Of 42 copper-base alloys contg. 20% Fe and various elements as Al, Si, Zn, Co, Cr, Ni, Mn, Ag, Sn and Be, only the alloy contg. 0.6% Be, 1% Ni and 20% Fe was improved in mechanical properties by heat treatment.
Hideo Nishimura

Structural changes due to quenching and tempering of β-phase alloys of the copper-antimony system. Atomi Ōsawa and Nisaku Sibata. *Science Repts. Tohoku Imp. Univ.*, First Ser. **28**, 197-216(1939).—See *C. A.* **33**, 3736[6]. A. D.

The copper-rich alloys of the copper-nickel-phosphorus system. D. K. Crampton, H. L. Burghoff and J. T. Stacy. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. **1142**, 17 pp.(1940).—The solidus surface and limits of α solid soly. were detd. for Cu-Ni-P alloys contg. up to 8% Ni and 1% P. Soly. of Ni and P decreased markedly with decreasing temp., as little as 0.2% Ni + P forming a second phase at 500° when present in suitable proportions. Because of this low soly., attractive combinations of cond. and strength were shown to be obtainable in quenched and aged alloys. Best properties were found to be obtained in alloys in which the ratio of Ni to P was about 5:1. The exact nature of the pptg. phase was not established in the investigation, but it appeared that the phase pptd. in the age-hardening range of temps., at and below about 500°, was different from that pptd. at somewhat higher temps. Investigation of the properties of alloys contg. Ni and P in the ratio of about 5:1 showed that the most useful hardenability is attained in alloys contg. about 1.25 to 1.5% Ni + P and that hardness or strength attainable by age-hardening increases only gradually for higher alloy contents. Such alloys were found to be capable of extensive cold-working after age hardening, so that the strength could be still further increased. Addn. of alloying elements such as Sn, Cd and Zn yielded slightly modified but also attractive properties, strength being increased while cond. was somewhat decreased. C. L. Mantell

Ternary α-solid solution of copper-nickel-silicon alloys. Masazō Okamoto. *Nippon Kinzoku Gakkai-Si* **3**, 411–20 (1939); cf. *C. A.* **33**, 3315[2].—The solid-soly. of the α-field of the Cu Ni-Si alloy system was detd. The phases pptd. from the α-solid solns. are found to be χ (which further decomps. slowly into α and γ), γ, γ′ or β_1. The aging behaviors of about 70 specimens of the ternary supersatd. solid solns. quenched at temps. at which the thorough soln. into α-solid solns. takes place, by tempering at 435–550°, were exaind. by a Vickers hardness tester. The alloys on the line $CuNi_2Si$ shown by Corson (cf. *C. A.* **21**, 1090) show marked age-hardening, but those alloys cannot always be said to show the max. age-hardening. E. g., the alloys 0.5% Si-3% Ni-balance Cu and 0.5% Si-6.0% Ni-balance Cu show good hardenabilities. The marked hardenability by tempering can be obtained in the alloys having the γ′-precipitant and the large soly. change. Hideo Nishimura

Transformations in eutectoid alloys of copper and tin. III. Conditions of formation of the β′-phase. I. Isaichev. *J. Tech. Phys.* (U. S. S. R.) **9**, 1286–92(1939); cf. *C. A.* **28**, 4356[5].—The β′-phase of martensite type is obtained on quenching of alloys contg. 23.6–25% of Sn. It has a definite orientation relative to the β-phase from which it is prepd. X-ray patterns were used. J. J. Bikerman

The preparation of solid chromium-nickel alloys by reduction of chromic oxide in the presence of nickel. G. Grube and K. Ratsch. *Z. Elektrochem.* **45**, 838–43(1939). —The reduction of Cr_2O_3 in the presence of Ni by H_2-H_2O mixts. at temps. of 1100°, 1200° and 1300° was studied. Alloys contg. from 0.09 to about 69% Cr were obtained. Curves are given showing the O_2 pressures (calcd. from the known dissocn. of steam) of Cr_2O_3 in equil. with various Cr-Ni alloys. H. C. Thomas

Production of solid columbium-nickel alloys by reduction of columbium pentoxide in the presence of nickel. G. Grube, O. Kubaschewski and K. Zwiauer. *Z. Elektrochem.* **45**, 881–4(1939).—Previous literature states that pure Cb_2O_5 is reduced only to Cb_2O_3 in H_2 at atm. pressure. Reduction to the metal was successful in pressed mixts. of Ni carbonyl powder and Cb_2O_5. Metallic, compact Cb-Ni alloys with a Cb content of 37% were obtained at 1100–1150° in dry H_2. Appreciable H_2 absorption by the alloys can be avoided if H_2 treatment is stopped immediately after the conclusion of the reduction. Alloys ob-

tained in this way were used for thermal, microscopic and x-ray expts. on the phase diagram of the Ni-Cb system. Addn. of Cb to Ni lowers the solidification temp. to a eutectic melting at 1265°; the eutectic point is assumed at 24% Cb. At the eutectic temp. approx. 20% Cb is dissolved in solid Ni; with decreasing temp. the soly. decreases decidedly. Between 24 and 31% Cb a type of crystal crystallizes from the melt which possibly has the formula Ni_3Cb. M. McMahon

Temper-hardening of nickel alloys containing silicon. Keizō Iwase and Masazō Okamoto. *Nippon Kinzoku Gakkai-Si* **3**, 405–11(1939).—Ni alloys contg. less than 9% Si were quenched at the temp. at which complete solid soln. is obtained and tempered at 550-700°. The alloys contg. 7% Si showed max. hardenability, even if the alloys contg. 9% Si were harder. The addn. of 5% and 10% of Cu raises the hardness of alloys both of tempered and quenched states with the shortening of the tempering time required to attain the max. hardness. The influences of 2% of Fe or 2% of Co on the temper-hardening of Ni-Si alloys are similar. Both elements decrease the aging rate of the alloys and make the temper-hardenability large. The addn. of Al hardens the alloys, the form of the time-hardness curve resembling that of Ni-Si binary alloys. Five % Si-Ni alloy showed temper-hardening upon the addn. of more than 4% Mn. Hideo Nishimura

Low-temperature silver-brazing alloys. H. A. Folgner. *Iron Age* **142**, Pt. II, No. 15, 161–2, 164–9, 290(1938).—The applications of Sil-Fos (Ag 15, Cu 80, P 5%) and Easy-Flow (Ag 50% with equal proportions of Cu, Zn and Cd) are described. A special flux is required. B. C. P. A.

The influence of different elements on the system iron–iron sulfide. Rudolf Vogel. *Naturwissenschaften* **27**, 761–4(1939).—A review of recent work by V. and coworkers on the effect of foreign elements on the Fe-FeS equil. Part of the work has been published: for C (*C. A.* 25, 5655), for P (*C. A.* **26**, 410), for V (*C. A.* **33**, 524[1]), for Cr (*C. A.* **32**, 4125[7]), for Mn (*C. A.* **31**, 7321[9]), for Ni (*C. A.* 25, 672). Results with Si and Ti are to be published. The systems mentioned are briefly discussed and schematic diagrams given. The importance of this work for desulfurization of iron, for the prepn. of S steels and for the structure of meteorites is stressed. B. J. C. van der Hoeven

The rate of precipitation from supersaturated aluminum-magnesium solid solutions after cold-work deformation. H. Vosskühler. *Metallwirtschaft* **18**, 873–7(1939).—Two tech. Al-Mg alloys contg. 8.76 and 3.65% Mg, besides traces of Mn, Fe and Si (less than 0.72%) were annealed for 4 hrs. at 420°, quenched in water, cold-rolled (0, 20, 40 and 60%) and subsequently tempered at 200° for periods up to 1000 hrs. The effect of various periods of tempering on tensile strength, yield point, elongation and elec. resistance was recorded graphically and structurally. The tensile strength curves show first a steep drop due to crystal recovery, then a rise as a result of pptn., followed by another, gradual, drop due to coagulation of the ppts. The alloy with 3.65% Mg showed recrystn. after 1 hr. when tempered at 250° but started to recrystallize at 200° after heating for 50 hrs. H. S. van Klooster

Barrel polishing. E. G. West. *Machinery* (London) **54**, 760-1(1939); cf. *C. A.* **34**, 1285[7].—Ball-burnishing is frequently used for plated articles. The cold-working action of the balls causes hardening of the deposited metal. Care must be taken to prevent removal of the plate at corners and edges. Ag and Au deposits are polished by this method; a soap soln. is used. The resulting finish often possesses enhanced corrosion-resisting properties. Times may vary between 15 min. and 2 hrs. The burnishing for Ni is longer, up to 4 hrs. Heavier balls and still longer periods are used for Cr-plated articles. Cd, Sn and Zn plates may be ball-burnished. Pores, detrimental to corrosion resistance, may be closed to a certain extent. Slightly oily sawdust may be used for the final barreling. Richard P. Seelig

Protecting metals by organic coatings. O. J. Schierholtz. *Can. Metals Met. Inds.* **3**, 1–5, 11(1940).—A discussion of the use of org. coatings in the prevention of corrosion. Nine factors contributing to paint failures are noted. Corrosion prevention may be effected by: (*a*) exclusion of moisture and other atm. destructive agents through provision of a finishing coat which is as impermeable as possible, and (*b*) electrochem. protection in the primer coat, by including substances which tend to stifle the chem. processes which cause corrosion. The efficiency of a coating as regards exclusion can be detd. by a cond. test. Water vapor diffusion tests indicate wide differences in permeability of various org. substances. The problem of adhesion, the methods of application, primer and finishing coats, pigment dispersion and pigment-vehicle ratio, and vehicles are briefly considered. W. H. Boynton

Laboratory corrosion tests. Goldowsky. *Bull. soc. roy. belge ing. ind.* **1939**, 803–19.—A discussion of the general principles governing the choice of corrosion tests, specifically for light alloys. Service conditions, corrosive media (air, sea water, ethyl gasoline) and features of design (welds, rivets, protective coatings) are considered. Leopold Pessel

Soil-corrosion studies, 1937. Corrosion-resistant materials and special tests. Kirk H. Logan. *J. Research Natl. Bur. Standards* **23**, 515–42(1939)(Research Paper No. 1250); cf. *C. A.* **33**, 5345[9], 9267[2].—Approx. 1600 specimens of ferrous and nonferrous materials were examd. after soil exposures of from 5 to 9 yrs., and the results are tabulated. No marked differences in the corrodibility of ferrous materials prepd. by different methods were observed. Addn. of small amts. of Cr, Cu or Ni to Fe or steel had no marked effect. Ferrous alloys contg. large amts. of Cr showed definitely lower rates of loss of wt. than other ferrous materials. They had fewer pits per unit area, but the alloys contg. Cr only were pitted deeply in certain soils. Addn. of Ni to Fe-Cr alloys appeared to improve the corrosion resistance. An alloy contg. Cr 23, Ni 13, Mn 1.8% showed less corrosion resistance than one contg. slightly lower amts. of these constituents. Two ferrous alloys contg. Ni and Cu in considerable amts. showed better resistance than the other ferrous alloys with the exception of those contg. high amts. of Cr. Cu and its alloys corroded at much slower rates at most test sites than the commonly used ferrous alloys. Dezincikification affected specimens of high Zn content in several soils. Most of the coatings inspected reduced the extent of corrosion of the pipes, as compared with unprotected pipe, but became severely affected themselves. A vitreous enamel and two thick rubber coatings provided almost complete protection to the specimens to which they were applied, without showing any visible sign of deterioration. Leopold Pessel

The corrosion of aluminum in different types of mortar. L. Tronstad and R. Veimo. *Aluminium* **21**, 839–42(1939).—Cement mortars attack Al, owing to an alk. reaction; the attack increases with increasing alky., porosity and humidity of the mortar. The mortars investigated were portland cement (pH 12.75 ± 0.1), slag cement (12.75 ± 0.1), aluminous cement (11.9 ± 0.1), stucco gypsum (7.6 ± 0.1), floor gypsum (6.9 ± 0.1). Eloxation of Al does not protect it against cement mortars. Asphalt coatings on Al in alk. mortars swell considerably and are partly destroyed; asphalt emulsions in particular cannot be recommended because of their peptization. The corrosion of Al in gypsum mortars can be suppressed almost entirely by surface protection by eloxation or by coating with asphalt; adhesion is, however, not very good, especially in floor gypsum. M. Hartenheim

Corrosion-resisting properties of bronze condenser tubes. II. Electrode potential-time relations. J. Chapman and J. W. Cuthbertson. *J. Soc. Chem. Ind.* **58**, 330–4(1939); cf. *C. A.* **33**, 4941[9].—Electrode-potential measurements were obtained for four bronzes (85–87 Cu, 12–14 Sn, 0.03–0.14 P). Curves were plotted for (*a*) stagnant sea-water; and for sea-water stirred by (*b*) N_2, (*c*) air and (*d*) O_2. The 14 and 12% Sn alloys were most

resistant to *a*, *c* and *d*; whereas cupro-nickel was best in *d*. Film pretreatments were chosen from the above time-potential curves. Increased protection toward sedimentation attack was found for cupro-nickel and bronze alloys. This attack was simulated by placing fine sand on the submerged sample of condenser tubing. F. W. Fink

Cause of and remedy for pitting and corrosion of locomotive tubes and sheets with special reference to status of embrittlement. R. E. Coughlan, *et al.* *Am. Ry. Eng. Assoc., Bull.* No. 414, 214–19(1939); cf. *C. A.* **33**, 2257[1].—"Embrittlement" or "intercryst. corrosion," in riveted seams of locomotive boilers has been encountered and definitely identified on a no. of American railroads. Intercryst. cracking is not due to water conditions alone but to a combination of factors that simultaneously create following conditions: (1) An embrittling water; (2) high cold working or applied stress in the metal; (3) slow leakage and concn. in the riveted seam; and (4) contact of the concd. soln. with the stressed metal. Experience with locomotives indicates that neither Na_2SO_4 nor a combination of Na_2SO_4 and NaCl afford protection. Use of lignin-contg. materials, such as sulfite liquor, and tannins, such as quebracho, under controlled conditions has materially reduced cracking. "Embrittlement Detectors" developed by the Bureau of Mines have been applied to locomotives in different sections of the country for checking the embrittling characteristics of various water conditions, and corrective treatment is being applied where warranted. R. C. Bardwell

Corrosion of steels and protection by means of oily paints. Bancelin. *Bull. assoc. franç. techniciens pétrole* No. 50, 95–121(1939).—The effects of natural agents such as water and air on the corrosion of iron are discussed in contrast to the action of chem. agents such as acids. The prepn., testing and application of oily paints for protection against natural corrosion are outlined. E. J. Mahler

Properties of light-metal welds. Study of the corrosion resistance of welded aluminum alloys. P. Brenner. *Metal Ind.* (London) **55**, 405–8, 429–33; *Aluminium* **21**, 846–54(1939).—Sheet specimens of 8 light alloys were gas welded (butt welds) and exposed to a stirred soln. contg. 3% NaCl and 0.1% H_2O_2. At various time intervals, specimens were withdrawn for tensile tests and microscopic examn. With Cu-free alloys, the test period was extended for 2 years. Pure Al and the Al-Mn and Al-Mg-Mn alloys showed greatest resistance. After 2 years, their loss of strength was negligible, even if the welds were hammered. An Al-Mg alloy which was in the unwelded state approx. as corrosion-resistant as the above-mentioned alloys showed considerable loss of strength in the welded condition. This behavior was connected with the quantity and character of the Mg_2Al_3 compd. sepg. from the solid soln. Coarser pptns. were less harmful than fine ones and tests indicated the possibility of improvement by the use of initially heterogeneous material. An Al-Cu-Mg alloy (Pantal) lost about 20% of its strength in the unwelded age-hardened condition after a 2-year corrosion test, and about 30% in the welded condition. Re-hardening the welded material restored its strength and corrosion resistance. The Al-Cu-Mg alloy (Bondur) showed low resistance, especially after welding. Considerable improvement could be effected by the use of plated material, pure Al plate being superior to a plate of Al-Mg-Si alloy. Thirteen references. Leopold Pessel

The metallography of welded steel, cast iron and malleable cast iron. F. Roll. *Metallwirtschaft* **19**, 19–21 (1940).—A review. G. G.

The heat economy in the open-hearth furnace. Saburo Umino. *J. Fuel Soc. Japan* **18**, 635–49(English abstr. a65)(1939).—From the practical results of 42 furnaces it is concluded that about 1.45×10^6 kilocalories is necessary to increase the capacity by 1 ton of steel per hr. and that the capacity is independent of the variety of fuel. The heat consumption per ton of steel decreases with the increase of the capacity. The refining time per ton of steel is inversely proportional to the heat supplied in unit time, and the time is always longer with a cold charge than with a mixed charge of molten pig from scrap. The heat quantity to be supplied per unit time increases with the increase of the furnace size. In a charge of cold pig iron with scrap, heat of about 0.274×10^6 kilocalories must be added for an increase of 1 ton in the size of the furnace; whereas, in molten pig about 0.046×10^6 kilocalories is supplied. An increase of the furnace size, however, diminished the fuel consumption per ton of steel, almost independently of the charge. The capacity per unit size of furnace in Japan and in Germany is about 6 and 5 times that in U. S. A., resp. F. I. N.

The mixing of alloy cast irons. H. Uhlitzsch and K. Appel. *Giesserei* **26**, 266–73, 310–18(1939).—Cast-iron diagrams for 0.5% Ni, 1.5% Ni, 0.25% Mo, 0.75% Mo, and 0.5% Cr were established from about 140 Ni, Mo and Cr alloyed test melts; the diagrams include the pearlitic field for test-piece diams. of 30, 20, 10 and 6 mm. The ratio of wall thickness to test-piece diam. was detd. by comparing analysis results of the cast piece with the diagram. All 3 alloying metals broaden the pearlitic field, Ni displaces the left boundary line to the left and the right to the right, while Mo and, in a greater degree, Cr both move the limit curves to the right. From the displacement of the left pearlite line by Δ Si, the ratios (Ni: Δ Si), (Mo: Δ Si) and (Cr: Δ Si) were formed, which are found to be independent of the percentage of the added metal. Thus the plan of mixing diagram for the 3 named alloying metals succeeded in including C, Si, added metal and wall thickness or piece diam. and made possible a simple calcn. of alloying. This was checked with numerous examples of calcns. Alloy diagrams for simultaneous addns. of Ni and Cr, as well as Ni and Mo, are outlined and also examples of calcns. are used. The diagram for the simultaneous addn. of all 3 alloys can also be made. The influence of the 3 addn. metals investigated on the structure and mech. properties is briefly considered. C. B. Jenni

Reducing ores such as those of iron. Frans M. Wiberg (to Det Norske Aktieselskab for Elektrokemisk Industri). U. S. 2,182,009, Dec. 5. App. is described, and a method comprising the steps of causing the ore to pass through a furnace in opposite direction to CO-contg. reducing gas, taking out a portion of the gas before it has continued through the whole body of ore, leading the portion of gas through at least one carburetor for regenerating the same with respect to CO and utilizing the same as reducing agent in the furnace, causing the rest of the gases to continue through the body of ore and supplying air to the same for effecting the required reduction temp., leading the process in the furnace so that only the partial reduction of the ore is effected, introducing the partially reduced ore together with solid reducing agent into a second furnace, where it is melted and completely reduced, and leading at least one portion of the gases generated in the second furnace through the carburetor together with

the portion of gases taken out from the first-mentioned furnace for assisting the reduction process in the furnace.

Apparatus for aerating, as in ore flotation. Lionel E. Booth. U. S. 2,182,442, Dec. 5. Various structural, mech. and operative details.

Extracting vanadium from vanadium-bearing silicates. Bruno Mayer (to Vanadium Corp. of America). U. S. 2,183,027, Dec. 12. A process of treating silicate furnace slags contg. a minor amt. of V and a relatively larger amt. of contaminant from the group consisting of Fe, Mn and Al comprises comminuting the slag, roasting it in an oxidizing atm. at a temp. of about 760–980°, and leaching the roasted slag with a mineral acid, the amt. and concn. of the acid being such as preferentially to ext. the V, leaving such ordinarily easily sol. constituents as the oxides of Fe, Mn, Al and Si for the most part in the insol. residue. Cf. *C. A.* **33**, 3546[8].

Pot suitable for use in melting metals for pressure casting. Nathan Lester (to Lester Engineering Co.). U. S. 2,182,403, Dec. 5. Various structural details.

Basic open-hearth furnaces. Alexander M. Morton. U. S. 2,182,674–5, Dec. 5. Various structural features.

Apparatus for introducing fuel into an open-hearth furnace. Levi S. Longenecker. U. S. 2,182,497, Dec. 5. Various structural and operative details. U. S. 2,182,498 relates to an open-hearth steel method which involves melting down a charge by intense flame of low luminosity directed against at least one side of the charge and refining with luminous flame alternately directed from opposite ends lengthwise of the furnace. App. is described.

Furnaces for melting and refining metals, etc. Stein and Atkinson Ltd. and Tom A. Booth. Brit. 507,936, June 23, 1939. The furnace chamber is provided with 1 or more tuyère openings which may be closed or into hich removable tuyère devices are insertable and the chamber is adapted for being maintained in rotation or in such oscillation about a longitudinal axis that the tuyère openings pass below the surface of the charge.

Continuous heat-treating furnace. Arthur H. Vaughan (to Electric Furnace Co.). U. S. 2,181,928, Dec. 5. Various structural and operative details of a forced-circulation fuel-fired furnace suitable for use in annealing metals, etc.

Metallurgical furnace suitable for heating strip metal in coils. James C. Woodson (to Lee Wilson Engineering Co.). U. S. 2,182,218, Dec. 5. Various structural and operative details.

Apparatus for heat-treatments such as hardening metal articles. Warren H. Farr (to Budd Wheel Co.). U. S. 2,182,790, Dec. 12. Various structural, mech. and operative details.

Apparatus for heat-treating and hardening the ends of railroad track rails. Frederick M. Graham. U. S. 2,182,120, Dec. 5. Various structural, mech. and operative details.

Drum furnaces for the bright-annealing of metal articles conveyed in countercurrent, with heat recovery and exclusion of air by means of a protective gas atmosphere. Deutsche Waffen- und Munitionsfabriken A.-G. Brit. 508,061, June 19, 1939. These comprise a rotating drum in which the articles are introduced through a heat-exchange zone into a heating zone, and a 2nd drum, arranged concentrically with the 1st, in which, on returning, the articles pass successively through the heating zone, then through the heat-exchange zone and finally through a cooling zone.

Apparatus for annealing portions of metal tubes, etc. Frederick C. Kuhnle (to American Brass Novelty Co.). U. S. 2,182,294, Dec. 5. Various structural, mech. and operative details.

Continuous strip annealing furnace. Albert N. Otis (to General Elec. Co.). U. S. 2,181,738, Nov. 28. Various structural and operative details of a furnace for simultaneously annealing a plurality of sep. strips.

Muffle furnace utilizing steam, for blue-finishing steel strip. Aaron Simon (to Triangle Mechanical Laboratories Corp.). U. S. 2,182,060, Dec. 5. Various structural and operative details.

Apparatus suitable for heating the ends of aluminum tubes in brazing them, etc. Philip A. Smith (to Western Cartridge Co.). U. S. 2,182,364, Dec. 5. Various structural and operative details.

Apparatus for heating metal bodies, as in effecting flame hardening. Cecil V. Eskridge (to Oxweld Acetylene Co.). U. S. 2,181,937, Dec. 5. App. for heating metal bodies comprises at least two blowpipe heads individually provided with a plurality of outlets disposed in a plurality of substantially parallel rows, the outlets of each row being disposed in staggered relation with respect to the outlets of an adjacent row, the heads having mutually abutting edges inclined with respect to the parallel rows of outlets; and means for supplying a combustible mixture of gases to the outlets.

Apparatus (with a rotatable retort and spiral screw conveyor) for continuously heating and cooling ferrous or nonferrous metals, as in bright-annealing of small pieces. Kristian A. Juthe (to American Electric Furnace Co.). U. S. 2,182,616, Dec. 5. Various structural, mech. and operative details.

Metal-treating apparatus suitable for pickling coils of metal strip. Florence C. Biggert, Jr., and Charles F. Buente (to United Engineering & Foundry Co.). U. S. 2,181,503, Nov. 28. Various structural, mech. and operative details.

Treating metal powders such as copper and iron. Joseph E. Drapeau, Jr., and Louis G. Klinker (to Glidden Co.). U. S. 2,181,123, Nov. 28. The compressibility of a powd. metal such as Cu, a Cu alloy or Fe, when compressed into solid shapes such as bearings, is improved by subjecting the powder to mech. deformation, as by use of an impact hammer, to set up internal stresses in the powder particles and thereafter heating the powder in a nonoxidizing atm. at a temp. and for a time sufficient substantially to reduce the internal stresses, but sufficiently below the m. p. to prevent sintering, while preserving the powd. character of the material.

Separating copper and zinc from their alloys. Charles R. Kuzell (to Phelps Dodge Corp.). U. S. 2,182,128, Dec. 5. App. is described, and a method which involves subjecting the molten alloy to the action of an oxidizing gas to oxidize the Zn and sweep a portion of the oxidized Zn out of the treating receptacle, subjecting the residue to the action of a reducing agent such as coke while molten to reduce contained ZnO, and vaporizing the resulting elemental Zn. U. S. 2,182,129 relates to a generally similar method in which, after the treatment with oxidizing gas, a molten oxide or slag phase contg. ZnO is sepd. from the metal phase contg. Cu and subjected to the action of a reducing agent for Zn liberation.

Zinc. Melville F. Perkins and Roland G. Crane (to American Smelting and Refining Co.). U. S. 2,181,148, Nov. 28. App. is described, and a process for treating oxidized zinciferous material such as an oxidized ore or calcine, which involves charging it, together with solid carboniferous material such as coke dust (both materials being in a fine state of subdivision), into a retort wherein the zinciferous material is reduced in suspension, passing the products of reaction as a stream to an incandescent carboniferous bed, supplying an oxidizing gas to the stream in amt. sufficient to oxidize the carboniferous suspensoids entrained in the stream and render the carboniferous bed self-cleaning, passing the stream through the bed, and recovering Zn from the emerging gases.

Porous metal articles such as bearings formed of powdered copper and tin. Wm. F. Bolesky, Walter Waleke and John A. Lutz. U. S. 2,182,741, Dec. 5. In making porous metal articles by heating compressed powd. metals such as Cu and Sn in approx. the desired shape to an alloying temp., there is incorporated in the initial mixt. a powd. material of vegetable origin such as soybean meal having a natural oil content held in its cellular structure, this material being forced to the outer surfaces of the body undergoing heating and serving to give the article a uniform porous structure.

Apparatus for testing the indentation and scratch hardness of materials such as metals. Eugene P. Polushkin.

U. S. 2,182,235, Dec. 5. Various structural, mech. and operative details.

Thin-walled internal-combustion engine pistons suitable for plating with cadmium. Russell H. McCarroll (to Ford Motor Co.). U. S. 2,181,947, Dec. 5. A sand casting is formed of Fe together with C 1.0–2.0, Mn 0.5–1.5, Si 0.5–1.5, Cu 1.5–3.5, P 0.12% or less and S 0.16% or less, the casting is heated to about 900° for 20 min., then air-cooled in 30 min. to about 650°, then reheated to about 760° and held at this temp. for an hr., then gradually cooled to about 540° in an hr., then air-cooled to room temp. and machined to finished dimensions.

Steel. John C. Witherspoon (to American Steel and Wire Co. of N. J.). U. S. 2,181,468, Nov. 28. A method of producing low-metalloid steel in a basic open-hearth furnace involves regulating the slag on the bath in the furnace so that when the C content of the bath is reduced to around 0.1% the Fe oxide content of the slag substantially exceeds the silica content of the slag, and at that time adding sufficient siliceous material to the slag to drop the C content of the bath to a C content within the range of low-metalloid steel in not more than 25 min. when operating at furnace temps. of 1650° or less.

Steel treatment. Samuel Epstein and Hugo C. Larson (to Bethlehem Steel Co.). U. S. 2,181,695, Nov. 28. In the manuf. of rimmed steel, Fe oxide and a highly oxidizing reagent such as $KClO_3$, $NaNO_3$, $KMnO_4$ or $K_2Cr_2O_7$ are added to the molten metal after tapping, and serve to control rimming action.

Alloy steel. Gustav A. Reinhardt (to Youngstown Sheet and Tube Co.). U. S. 2,182,135, Dec. 5. See Can. 385,709 (*C. A.* **34**, 1300[7]).

Steel containing lead. Oscar E. Harder (to Inland Steel Co.). U. S. 2,182,758, Dec. 5. A steel contg. C up to 1.7% and substantially uniformly dispersed Pb 0.1–0.478% has its machinability so improved by the presence of the Pb that a sawability test shows an index better than that of otherwise similar steels contg. no Pb. U. S. 2,182,759 relates to alloy steels such as those contg. 0.5–6.0% of metals such as Cr, Ni, Mo, etc., together with C up to 1.7, Si up to 2.5, P up to 0.15, S up to 0.3 and Pb 0.03–1.0%, together with Fe, and in which the Pb gives improved machinability.

Cobalt alloys suitable for dental castings. Arthur Szabo (to Nobilium Products, Inc.). U. S. 2,182,041, Dec. 5. Alloys may be formed approx. of Co 55, Cr 28, Fe or Ni 7, Pt, Pd or Ir 9, W 0.5, Si 0.2 and C and impurities 0.3%.

Iron alloys. Joseph V. Emmons (to Cleveland Twist Drill Co.). U. S. 2,183,014, Dec. 12. Alloys which are suitable for dies, etc., contain Fe together with C about 0.15–1.6, Mn about 4 or less, Cr about 3.25–6.0, Si about 3 or less, W about 8–20, Ni 0.1–10 and Mo about 12–28% of the amt. of W present. Cf. *C. A.* **34**, 1301[8].

Nickel-cadmium alloys. Franz R. Hensel (to P. R. Mallory & Co.). U. S. 2,182,380, Dec. 5. An alloy contg. Ni about 80% and Cd about 20% is suitable for elec. make and break contacts.

Electrical contacts. Franz R. Hensel and Earl I. Larsen (to P. R. Mallory & Co.). U. S. 2,182,381, Dec. 5. An alloy of Cu with Tl 20% or less is suitable for forming contacts, and may also contain Cd, Zn, Se, As, Ca, Mg, Hg or S.

Tubes, etc., for use at high temperatures in heating fluids such as in cracking oils under high pressure. Harold D. Newell (to Babcock & Wilcox Tube Co.). U. S. 2,182,177, Dec. 5. Tubes, etc., having high-creep strength and corrosion-resistance properties are formed of an Fe alloy contg. Cr about 2 0–3.25, Mo about 0.9–1.75 and C below 0.2%.

Coating screw threads. Charles E. S. Place (to Clare L. Brackett). U. S. 2,181,835, Nov. 28. A coating mixt. is used consisting of an aq. dispersion of wetted graphite in latex in the proportions of 10% or less by wt. of latex dry solids to graphite.

Apparatus for quenching articles such as those just galvanized. Ray C. Kivley (to Western Elec. Co.). U. S. 2,182,966, Dec. 12. Various structural, mech. and operative details.

Corrosion preventive compositions for coating metals. Robert B. Lebo (to Stanco, Inc.). U. S. 2,182,992, Dec. 12. A compn. suitable for coating articles of iron, Cu, brass, Al, etc., is formed of degras and an equal or smaller proportion of an alkali metal salt of an oil-sol. sulfonic acid material derived from the treatment of a petroleum oil with concd. H_2SO_4 (suitably in mixt. also with petrolatum or petroleum naphtha or a petroleum lubricating oil).

Welding seams in materials such as ferrous metals. George M. Deming (to Air Reduction Co.). U. S. 2,182,796, Dec. 12. Various details of app. and operation.

Welding flux and welding rod. Arthur R. Lytle and Thomas H. Vaughan (to Dominion Oxygen Co., Ltd.). Can. 386,702, Feb. 6, 1940. An Al-base alloy is coated with a mixt. of an inorg. welding flux and a partial polyvinyl acetal resin acetalized with propionaldehyde 52–82, butyraldehyde 42–82 or valeraldehyde 33–62%. The resin burns slowly without disagreeable odors, and without depositing a char.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Review of organic and physiological chemistry. K. Felix. *Jahreskurse ärtzl. Fortbild.* **30**, No. 11, 35–44 (1939).—A brief review of recent work on vitamin E, α-, β- and γ-tocopherols, durohydroquinone and pseudocumohydroquinone and some of their derivs., nicotinamide, adermine, aneurine, cocarboxylase, corticosterone, dehydrocorticosterone, hydroxycorticosterone, hydroxydehydrocorticosterone, progesterone, adrenosterone, *d*-amino acid oxidase, xanthine oxidase and a "new yellow enzyme." Ruth Berggren

Potential use of hydrogen fluoride in organic chemical processes. J. H. Simons. *Ind. Eng. Chem.* **32**, 178–83 (1940).—Anhyd. H_2F_2 is available in quantity, by distn. from CaF_2 and H_2SO_4, at 20–50 c. per lb. The product contains 0.1–0.2% of H_2O, less than 0.1% of SiF_4 and a trace of SO_2. It is a powerful alkylating agent somewhat analogous to $AlCl_3$ but giving less of tarry by-products. Acylations proceed smoothly and many ring closures and special reactions are catalyzed. Halogenated compds. have the less active halogens replaced by F, such as conversion of $PhCCl_3$ to $PhCF_3$. H_2F_2 catalyzes most of the reactions promoted by H_2SO_4, H_3PO_4, $AlCl_3$ and BF_3 but efforts to correlate such properties with structure were unsuccessful. In none of the condensation reactions is F introduced into the structure if halogens are absent. High efficiency, low yield of by-products or tars and ease of recovery suggest advantages in many applications. Anhyd. H_2F_2 does not react with most metals in the absence of H_2O and O_2. It can be handled in steel but not in cast iron. Cu is preferable to Fe for condensation vessels as formation of FeF_3 on the surface is believed to promote tar formation. Resins, cellulose and silica-contg. materials must be avoided. Foster Dee Snell

The development of the technical applications of hydrogenation. E. F. Armstrong and K. A. Williams. *Chimie & industrie* **42**, 234–42(1939); *Chemistry & Industry* **1940**, 3–9. E. H.

Preparation of some pure hydrocarbons for the purpose of testing the physical methods in use for the examination of hydrocarbon mixtures. I. H. I. Waterman, J. J. Leendertse and D. W. van Krevelen. *J. Inst. Petroleum* **25**, 801–8(1939); cf. *C. A.* **32**, 6847[4].—The method of synthesis and phys. properties of octylbenzene, octylcyclohexane, hexadecane, octadecylbenzene, octadecyl-

cyclohexane, and hexatriacontane are given. For these compds. the no. of rings per mol. may be derived from the sp. refraction with an accuracy of 0.2 ring per mol. In calcg. the no. of tertiary C atoms by a comparison of the no. of rings per mol. derived from the sp. refraction and also from the sp. parachor, about 1 tertiary C atom would be found, which, within the limits of accuracy of observational error, agrees with the actual content. II. H. I. Waterman, J. J. Leendertse and J. F. Sirks. *Ibid.* 809–12.—The octadecylcyclohexane prepd. from cyclohexyl iodide and octadecyl chloride has been shown to be identical with that prepd. from octadecylbenzene by hydrogenation at 200–60° using high-pressure H and Ni on kieselguhr as catalyst. Hydrogenation under these conditions did not cause undesirable structural changes. Joseph H. Wells

Physical properties of purified 2,2,3-trimethylpentane. Donald B. Brooks, Frank L. Howard and Hugh C. Crafton, Jr. *J. Research Natl. Bur. Standards* **23**, 637–41 (1939) (Research Paper No. 1259); cf. *C. A.* **33**, 2481[9].—2,2,3-Trimethylpentane was prepd. from *tert*-BuCl and MeCOEt by Grignard's reaction, the resulting methyl-*tert*-butylcarbinol converted to olefins which were fractionated, hydrogenated, and the resulting products purified and fractionated. App. and methods are described. The following properties were detd., the m. p. being in doubt: b_{760} 109.843°; dT/dp 0.0480° per 1 mm. Hg, n_D^{25} 1.40285, n_D^{15} 1.400038, dn/dt −0.000494 per degree, d_{25} 0.71617 g./ml., d_{25} 0.71218 g./ml., change of d. with temp. −0.000797 g./ml. degree. W. Purdy

Condensation of olefins and paraffins by means of sulfuric acid. H. I. Waterman, J. J. Leendertse and R. Hesselink. *Rec. trav. chim.* **58**, 1040–7 (1939) (in English). Mixts. of branched pentanes and pentenes were condensed at 0–9°, using H_2SO_4 as catalyst. The products formed (yields of 177% based on olefin) ranged from isobutane to mixts. b_{17} above 175°. Very little unsatn. remained in the products, and no cyclic compds. were present. A ratio of 3.1 of pentane to pentene was found to give the best yields in satd. products. The catalyst was very stable, having been used 7 times with no decrease in activity. The reaction is believed to take place in several or more stages, first the preliminary condensation of olefins and paraffins, then a partial destruction, then a further condensation between newly formed products. J. C. Lo Cicero

Production of active amyl alcohol from fusel oil. A. M. Birun. *Nauch. Zapiski Inst. Narodnogo Khoz. im. Plekhanova* **1938**, No. 1, 120–30; *Khim. Referat. Zhur.* 2, No. 4, 137 (1939).—The difference in the velocity of the chlorination of the active and the inactive amyl alc. was used for their sepn. The inactive amyl alc. is chlorinated 2.5 times faster, forming a chloride b. 101°. The chlorination expts. were performed by satg. amyl alc. (with α_D −2.13°, n 1.4095) with HCl under atm. pressure as well as in sealed tubes. In the 1st case the chloride was distd. off as soon as formed, in the 2nd case the alc. was satd. at 2–10° and heated in sealed tubes. After the process the chlorinated alc. was fractionated. A higher content of the active alc. was obtained from chlorination under pressure. To increase the yield of alc. it is not necessary to reach a complete satn. with HCl at room temp., but a highly active alc. with α_D 1.8° and contg. 75% of the active alc. was obtained from a complete satn. Optimum conditions for the chlorination were 108–11° for 3–5 hrs. W. R. Henn

Pyrolysis of the higher aliphatic alcohols. Henry Gault, Louis Palfray and Pao-Ting Hsu. *Compt. rend.* **209**, 999–1000 (1939).—On heating dodecanol at 200° with H under 100 kg. pressure in the presence of Raney Ni an approx. theoretical yield of undecane (I) was obtained. That this is not due to hydrogenolysis (cf. Wojcik, *et al.*, *C. A.* **27**, 1861) is proved by the same result being obtained when N replaces H. Varing the conditions showed the yield of I to increase with temp., pressure and time, and that under ordinary pressure a small quantity of lauraldehyde was actually obtained, whence it is inferred that this is first formed and then dissocd. to CO + I, the CO then reacting with H to form $CH_4 + H_2O$. C. A. S.

The nitro paraffins and their derivatives. C. L. Gabriel. *Chem. Industries* **45**, 664–8 (1939). E. H.

Preparation of aliphatic aldehydes by catalytic dehydrogenation of the alcohols in the liquid phase in the presence of nickel. Alexandre Halasz. *Compt. rend.* **209**, 1000–2 (1939); cf. *C. A.* **33**, 6255[7].—Various higher primary alcs. were heated with 5% Ni in a metal bath, the temp. being carefully regulated and kept const. The yield varies with time of heating and temp. and, though small, is generally better than obtained in any other way. Thus with lauric alc. heated at 250° the percentage of aldehyde formed increased with time to 20% after 2 hrs., but thereafter decreased. The yield also increased with the temp., e. g., after 1 hr. heating lauryl alc. at 220° gave 3.5%, at 250° 15% and at 280° 19%. Reduction of the pressure had no appreciable effect. Satisfactory results were obtained with the normal satd. alcs. contg. 11, 12, 14, 16 and 18 C. The aldehydes are readily sepd. as their bisulfite compds. C. A. Silberrad

The synthesis of polyenealdehydes by primary valence catalysis. W. Langenbeck and O. Gödde. *Atti X° congr. intern. chim.* **3**, 230–8 (1939) (in German).—Crotonaldehyde reacts with salts of piperidine to form 1-piperidylbutadiene (I) which condenses with AcH at 0°. This product is decompd. by means of Ac_2O-HOAc to piperidine and 2,4-hexadienal. I condenses with crotonaldehyde giving a product which undergoes an ionone-type of ring closure so that subsequent treatment with Ac_2O-HOAc yields dihydro-*o*-tolualdehyde and piperidine. However, if HOAc is present during the condensation, piperidine is split out before ring closure can occur and 2,4,6-octatrienal is the chief product. R. E. Reeves

Chemical constituents of sulfated oils. Robert M. Koppenhoefer. *J. Am. Leather Chem. Assoc.* **34**, 622–39 (1939).—One sample each of sulfated castor oil (I), sulfated neat's-foot oil (II) and sulfated cod oil (III) was analyzed by the usual methods and fractionated into sulfated compds., free fat acids and neutral oil by Hart's method (*C. A.* **31**, 4012[8]). The samples were com. oils of medium degree of sulfation. The fractions were examd. by the usual methods for oxidation, unsatn., hydroxylation, polymerization, etc. It was found: (1) The results of the fractionations agreed very well with those calcd. from the analyses of the oils. (2) About 20% of the combined SO_3 was lost during the fractionation, probably by thermal decompn. during removal of solvents. (3) Sulfation of I occurred primarily at the OH group, and secondarily at the double bond. Di-HO acids were identified in the fat acids recovered from the sulfated compds. (4) Sulfation of II occurred primarily at the double bonds of unsatd. acids. Monohydroxystearic acid was identified in the fat acids recovered from the sulfated compds. (5) Sulfation of III occurred at the double bonds, preferentially of the more unsatd. acids. The fat acids recovered from the sulfated compds. contained di-HO acids, and mono-HO unsatd. acids. (6) Free fat acids and neutral oil fractions from I and II were very little oxidized. Those from III were highly oxidized. (7) The neutral oil fractions contained large amts. of mono- and diglycerides. (8) Isoöleic acid was formed during the sulfation of II. H. B. Merrill

Syntheses of thioglycol from ethylene oxide and hydrogen sulfide. Hęou-Feo Tseou and Tsu-Ling Pan. *J. Chinese Chem. Soc.* **7**, 29–32 (1939).—Thioglycol is synthesized by passing ethylene oxide and H_2S through a pyrex tube filled with Fe or Al sulfide heated to 350°. When the reaction is well controlled the yield is practically quant. Wm. H. Adolph

Coördinated copper compounds with propylenediamine. Panchanan Neogi and Kanai Lal Mandal. *J. Indian Chem. Soc.* **16**, 433–6 (1939).—Attempts to prep. tris-propylenediamine salts with a view to their resolution into optical isomers led to the discovery of bispropylenediamine salts, which were not resolvable. These salts are of a violet color, very sol. in H_2O, yielding beautiful violet solns. The *d*-tartrate, *d*-camphorsulfonate and

d-nitrate were also prepd. and their rotations measured. A. H. Krappe

Synthesis of α-amino acids by means of alkylacetoacetic esters. I. V. V. Feofilaktov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 755–8(1939)(in English).—Continuing previous research (*C. A.* **34**, 378[3]), the coupling of alkylacetoacetic esters, $RCHAcCO_2Et$ (I), with benzenediazonium salts was carried out in an aq. alkali soln. in the cold for 4–6 hrs., the coupling product being a reddish brown oil (presumably of structure $RCAc(N{:}NPh)CO_2Et$ (II)), which was extd. with ether and hydrolyzed directly with alc. aq. alkali. After elimination of the alc. and acidification, the phenylhydrazone, $RC(:NNHPh)CO_2H$ (III), of the α-keto acid sepd. as a ppt. or brownish oil quickly transformed into a mass of yellow crystals. The reduction of III was carried out in alc. with Zn dust and alc. HCl in the cold (0°) for 6–8 hrs. After elimination of the alc. and of the excess HCl through distn. under reduced pressure, the residue was treated in water, first with $PbCO_3$, then with Ag_2CO_3. The filtrate was freed from the Ag by means of H_2S, and after evapn. the free α-amino acid was obtained. Similarly, isoleucine, alloisoleucine, leucine, phenylalanine, and alanine were obtained by coupling. A. H. Krappe

Synthesis of phenylalanine from benzylmalonic and benzylcyanoacetic esters through the phenylhydrazone of phenylpyruvic acid. II. V. V. Feofilaktov and E. Vinogradova. *Compt. rend. acad. sci. U. R. S. S.* **24**, 759–60(1939)(in English).—Expts. were carried out with a view to simplifying the method of the practical prepn. of the phenylhydrazones and the alkylpyruvic acids, starting from alkylmalonic and alkylcyanoacetic esters. Accordingly, the following scheme is recommended for the synthesis:

$$RCH(CO_2Et)_2 \rightarrow RC(:NNHPh)CO_2H \rightarrow RCH(NH_2)CO_2H$$

Thus through the coupling of PhN:NOK with benzylmalonic ester the phenylhydrazone of phenylpyruvic acid was obtained with a yield of about 60% of the theoretical amt.:

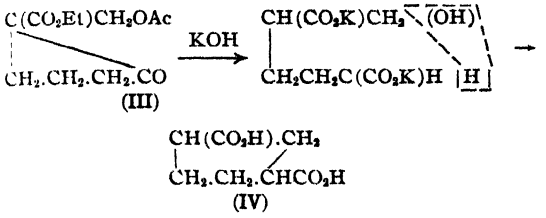
$$PhCH_2CH(CO_2Et)_2 \quad [PhCH_2C(N{:}NPh)(CO_2Et)_2] \rightarrow PhCH_2C(:NNHPh)CO_2H$$

Benzylmalonic ester, used as the initial product, had the following properties: b. p. 162° 19.5 mm.; n_D^{20} = 1.4871; d_4^{20} = 1.0763; *MR* = 66.85 (calculated 66.56). Similarly, through the coupling of K diazotate with benzylcyanoacetic ester the same phenylhydrazone of phenylpyruvic acid was obtained, the yield being 30% of the theoretical amt. 3 references. A. H. Krappe

Highly condensed products from some amino acids. Yukiti Go and Hisaya Tani. *Bull. Chem. Soc. Japan* **14**, 510–16(1939)(in German); cf. *C. A.* **29**, 1779[5].—Glycine-*N*-carboxylic anhydride, $OC.NH.CH_2.CO.O$ (I), m. 100°, is obtained in 92% yield from 35 g. (1 mol.) *N*-carbobenzoxyglycine on warming with 100 g. (5 mol.) $SOCl_2$ for about 1 hr. at 40° with the exclusion of moisture. *l*-Alanine-*N*-carboxylic anhydride, $OC.NH.CHMe.CO.O$ (II), m. 92° (decompn.), is obtained in 70% yield by warming 2.8 g. *N*-carboxymethoxy-*l*-alanine (from *l*-alanine and $ClCO_2Me$) with 4 cc. $SOCl_2$ at 40°, distg. off the excess $SOCl_2$ and heating to 65°. *l*-Leucine-*N*-carboxylic anhydride, $OC.NH.CH[CH_2CHMe_2].CO.O$ (III), m. 77–8° (decompn.), is obtained in 90% yield in an analogous way as II. I, II, and III give high-mol. compds. with the loss of CO_2 when kept in humid air or heated to 100° in pyridine. Expts. with polyglycine from I and with poly(glycine + leucine) (from equimol. amts. of I and III on heating in pyridine) showed that these compds. are not digested by enzymes. These findings and röntgenograms of the high-mol. compds. suggest that the compds. do not contain shorter chains than those present in hexapeptides. It is, however, impossible to decide whether the polymerization products contain long chains only or mixts. of long chains and rings. D. Stern

The optical activity of vitamin C. Br. Jirgensons. *Acta Univ. Latviensis, Kim. Facultat.* Ser. 4, No. 11 (in Lettish, 441–52; in German, 453)(1939).—The 0.05 *M* *l*-ascorbic acid showed $[\alpha]_D^{19}$ 24.1°. In the presence of 0.05–5.0 *M* HCl, HNO_3, H_2SO_4, or AcOH the optical activity remained unchanged. In the presence of 0.01–0.02 *M* NaOH, KOH, $EtNH_2$, Et_3N or NH_4OH it rose to 50°; in the presence of 0.05–0.25 *M* bases it ranged from 100 to 144°. In the presence of inorg. salts ranging from 0.1 to 2.0 *M* (NaCl, Na_2SO_4, KCl, KCNS, $FeSO_4$, $NiSO_4$, $MnCl_2$, $AlCl_3$, $SbCl_3$, $K_4Fe(CN)_6$) the optical activity changed very little; 2 *M* $CaCl_2$ lowered it; *M* $MgSO_4$, 0.1 *M* $BeSO_4$ and *M* $ZnSO_4$ raised it into the range 28–36°. $ZrO(NO_3)_2$ alone, with HCl or with NaOH elevated the optical activity as high as 70°. $Th(NO_3)_4$, especially in the presence of HCl or NaOH, increased it as high as +196°; in order to achieve this value the ratio: 1 mol. ascorbic acid, 2 mols. $Th(NO_3)_4$ and 5.5 mols. NaOH had to be maintained. In the presence of EtOH, MeOH or PrOH the optical activity rose slightly (30–50°); the amino acids glycine, alanine, valine, $NH_2CH_2CH_2CO_2H$, and sarcosine were more effective than the alcs., raising the activity into the range 45–60°; $NH_2CH_2CH_2CO_2H$ was the most potent of this group. F. Maresh

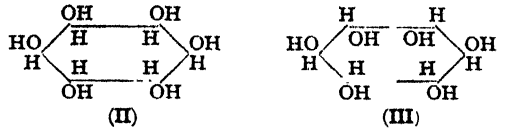
***tert*-Butyl esters of aliphatic dibasic acids.** H. J. Backer and J. D. H. Homan. *Rec. trav. chim.* **58**, 1048–61(1939)(in French).—Di-*tert*-Bu esters (I) of aliphatic dibasic acids with an even no. of C atoms (up to sebacic) have higher m. ps. than the neighboring odd-numbered acids. I also have higher m. ps. than the corresponding Me and Et esters with the single exception of $MeO_2C(CH_2)_8CO_2Me$. The striking oscillation in the m. ps. of I is apparent in the following series of m. ps. of the esters from the *oxalate* (II) to the *sebacate* (III) resp.: 71°, −7°, 36°, −10°, 32.5°, −15°, 29°, −18°, 18°. Two general methods were followed in the prepn. of the esters, the 1st, using C_5H_5N as catalyst, the 2nd Me_2NPh (IV). The acid chlorides (0.2 mol.) in 2 vols. of anhyd. C_6H_6 are added dropwise to 1 mol. Me_3COH (V) (dried over Na) in 0.6 mol. C_5H_5N (distd. over KOH). The reaction mixt. is agitated and maintained below 50°. Upon completion of the 1st stage the soln. is heated in a water bath for 3 hrs., cooled and the ppt. filtered and washed with C_6H_6. The filtrate is made acidic to Congo red and the 2 layers formed are sepd. The H_2O layer is extd. thrice with C_6H_6 and the combined C_6H_6 solns. are washed successively with 2.0 *N* H_2SO_4 and Na_2CO_3 soln., then dried over anhyd. Na_2SO_4 with a little fused K_2CO_3. The C_6H_6 is removed *in vacuo* and the products (except II) are likewise distd. *in vacuo*. When IV is used as catalyst $CHCl_3$ (dried over $CaCl_2$) is used as solvent and extns. are made with petr. ether. The following di-*tert*-Bu esters were prepd.: II (87% yield); *malonate*, b_{10} 93° (78% yield); *succinate*, b_{11} 115° (31%); *glutarate*, b_{13} 125.5°; *adipate*, b_{10} 134° (60%); *pimelate*, b_{11} 174° (60%); *suberate*, b_{11} 160° (64%); *azelate*, b_{13} 174° (70%); *sebacate*, b_{13} 185° (74%). Several mixed ester-salts were prepd. by sapon. of the acid radicals with alc. KOH. J. C. Lo Cicero



The reactivity of carbonyl cyanide. R. Malachowski. *Atti X° congr. intern. chim.* **3**, 240–1(1939)(in German).—Carbonyl cyanide resembles $COCl_2$ in its reactions with primary and secondary amines, HO groups and acid anhydrides. $PhNMe_2$ undergoes a condensation with the CO group of $CO(CN)_2$. No exptl. details. *Deuterium cyanide*, d_{15} 0.7198, m. 0.115° and b. 0.75° above the m. p. and b. p., resp., of HCN. R. E. Reeves

Diene syntheses. S. Goncharov. *Akad. Nauk. U. R. S. S., Inst. Khem. Tekhnol.* (Kiev) **1937**, 83 pp.—The progress made in the chemistry of cyclodienes is reviewed and analyzed. Attention is drawn to the ease and completeness with which a great many important compds. have been synthesized since Diels began his work with the azodicarboxylic esters (*C. A.* **4**, 319; **5**, 702; **18**, 2331; **22**, 1144). The study of group relationship in the diene syntheses helped in solving some of the broader problems

of stereochemistry. Numerous references are given. B. Gutoff



Aldehydo acids and aldo-enol lactones. IV. Specific transformations of certain aldehydo acids and γ-aldo-enol lactones in an alkali medium. M. M. Shemyakin. *Compt. rend. acad. sci. U. R. S. S.* 24, 768–72(1939)(in English); cf. *C. A.* 34, 89[1].—In continuing previous research, the transformation of certain aldehydo acids and γ-aldo-enol lactones in contact with alkalies leading to a dicarboxylic acid was examd. more closely. The acids so produced are of particular interest for stereochemistry. Five of them are truxillic acids, the remaining 6 truxinic acids, 2 of the latter being *new*, viz.: (1) m. 196°, empirical formula $C_{18}H_{16}O_4$. Isomerization into a known truxinic acid proved it to be 1 of the diphenylcyclobutanedicarboxylic acids so far unknown; (2) m. 245°. Some particulars about the truxinic acid, m. 196°, prepd. in the previous paper and its derivs. conclude the article. 7 references. A. H. Krappe

Norcamphoric acid (1,3-cyclopentanedicarboxylic acid). Henry Gault and Lyse Daltroff. *Compt. rend.* 209, 997–9(1939).—Et 2-ketocyclopentanecarboxylate (I) condenses with HCHO in the presence of K_2CO_3 to give Et 1-hydroxymethyl-2-ketocyclopentanecarboxylate (II), which cannot be sepd. from unaltered I. Sepn. was effected, however, by fractional distn. of the acetylation product of the mixed esters; that of the enolic form of I b_{17} 130°, and that of II b_{17} 160°. The latter (III) on hydrolysis gives norcamphoric acid (IV) in almost theoretical yield:

the ring being broken between 1 and 2, and reformed between the CH_2 of the CH_2OH group attached to 1 and 3. It has not so far been possible to det. whether the product is the cis or trans isomer. C. A. Silberrad

The constitution of conduritol and certain cyclohexanetetrols. Gerda Dangschat and Hermann O. L. Fischer. *Naturwissenschaften* 27, 756–7(1939).—Previous work on quinic and shikimi acids (*C. A.* 33, 5374) was continued with the related compds. conduritol (Kubler, *C. A.* 3, 1150), a tetrahydroxycyclohexene, and betitol (v. Lippmann, *Ber.* 34, 1159(1901)), a cyclohexanetetrol, m. 224°. Conduritol acetonates to a monoacetone compd., m. 100–1°, indifferent to $Pb(OAc)_4$, hence carrying the acetone group on C atoms 4,5 (cis). It is assumed that the 3- and 5-HO groups are trans. The diacetate of acetonconduritol, m. 79°, is oxidized by neutral $KMnO_4$ to a di-HO compd. (I) which upon treatment with $Pb(OAc)_4$ in C_6H_6 and further oxidation with $EtCO_3H$ and sapon. yields mucic acid. The tetraacetate of conduritol, $b_{0.6}$ 165°, oxidized in similar manner gives an intermediary product, tetraacetylmucic dialdehyde, decompg. 184°, and after $EtCO_3H$ treatment tetraacetylmucic acid, decompg. 246°. Allomucic dialdehyde tetraacetate, decompg. 164°, tetraacetylallomucic acid, decompg. 228°, and allomucic acid are prepd., resp., by acetylation of I followed by mild sapon. and $Pb(OAc)_4$ treatment, $EtCO_3H$ oxidation and by sapon. I is derived from 6,1,2,3/4,5 inositol (II), m. 270–5°, for which the name alloinositol is proposed. From the oxidation product of tetraacetylconduritol another inositol, decompg. 285–90°, structure 3,6/1,2,4,5 (III), is derived and named *mucoinositol*. This structure disagrees with the work of Grotepass (*Diss. Göttingen* 1931). The mucoinositol may be identical with the Posternak epiinositol (*C. A.* 31, 1774[9]). Catalytic reduction of conduritol gives dihydroconduritol, m. 204°; its acetone compd., m. 80°, is obtained by reduction of the conduritol acetone compd. By reduction of 4,5-isopropylidene-3,4,5-trihydroxycyclohexanone from quinic acid with Ni and H_2 under pressure or with $(iso\text{-}PrO)_3Al$ there is obtained after deacetonation a tetrol, m. 208°, α_D −8.3° (H_2O). By the Ponndorf method (*C. A.* 20, 1611) is obtained from the same substance after deacetonation an isomer, m. 151°, α_D −61.0° (H_2O). The 3 HO groups in both compds. have the same position as in quinic acid, consume 2 moles HIO_4. Reacetonation is difficult. Neither of the isomers is identical with betitol.

B. J. C. van der Hoeven

Preparation of several styrene derivatives by the action of organomagnesium compounds on *p*-cyclohexylacetophenone. I. Zugrăvescu and Mme. S. Zugrăvescu. *Bul. Soc. Chim. Romania* 20A, 225–30(1938).—In continuing the previous study (cf. *C. A.* 33, 4228[3]), efforts were made to replace the 2 Ph radicals by aliphatic groups by the action of the Grignard reagent on $p\text{-}C_6H_{11}C_6H_4\text{-}COMe$ (I) with a view of obtaining a carbinol of the type $p\text{-}C_6H_{11}C_6H_4C(OH)R_2$. This reaction, however, leads to mixts. of an alc. and an olefin (styrene deriv.) from which it was impossible to sep. the desired product, the formation of the olefin being favored by using an excess of the Grignard reagent, which apparently serves as a dehydrating agent. Treating 30 g. of I in Et_2O with the Grignard reagent prepd. from 25 g. EtBr and 4 g. Mg followed by heating 4 hrs., replacing the Et_2O with C_6H_6 and heating an addnl. 6-hr. period, and decompg. with AcOH after standing for 12 hrs., gave 26 g. *2-p-cyclohexylphenyl-2-butene*, b_{14} 169°; the structure of this olefin was proved by oxidizing with $KMnO_4$ to I and AcOH. Similarly, treating 30 g. I with the Grignard from 23 g. PrBr and 4 g. Mg yielded 18 g. of *2-p-cyclohexylphenyl-2-pentene*, b_{12} 157–8°, oxidation of which gave I and $EtCO_2H$. Treating 30 g. I with the Grignard reagent from 25 g. BuBr and 4 g. Mg yielded *2-p-cyclohexyl-2-hexene*, b_{18} 191–2°, oxidation of which gave I and $PrCO_2H$. I and PhMgBr likewise yielded *α-p-cyclohexylphenyl-α-phenylethylene*, b_{13} 223–4°. The above styrenes readily decolorized Br solns. John F. Lontz

Reaction capacity of the methyl group. V. Nitro- and dinitrotoluenes. Louis Chardonnens and Peter Heinrich. *Helv. Chim. Acta* 22, 1471–82(1939)(in French); cf. *C. A.* 28, 1343[6]; 33, 8596[4], 8597[3].—*p-Nitrobenzaldehyde p-dimethylaminoanil:* 13.7 g. *p*-nitrotoluene (I), 5 g. $p\text{-}ONC_6H_4NMe_2$ (II), 10.6 g. calcined Na_2CO_3 and 150 cc. alc. were refluxed for 40 hrs. After prolonged cooling the ppt. was washed with alc. and then with water, and dried. One crystn. from benzene and 2 from alc. gave 0.4 g. (1.5% yield) bronze-red platelets, m. 219°, sol. in benzene, Me_2CO and $CHCl_3$, difficultly sol. in alc. and Et_2O. *4-Nitrostilbene:* 13.7 g. I, 10.6 g. BzH and 4 g. piperidine (III) were refluxed at 175–85° for 16 hrs. The black residue was washed with a very small amt. of MeOH, dissolved in 10 cc. boiling glacial AcOH and allowed to stand for several days. Crystn. of the brown ppt. from AcOH and then MeOH gave 0.8 g. (3.5% yield) yellow needles, m. 155.5°. *4-Nitro-4'-dimethylaminostilbene:* 1.37 g. I, 1.49 g. $p\text{-}Me_2NC_6H_4CHO$ (IV) and 0.4 g. III were refluxed at 175–185° for 16 hrs. The dark red mass was ground with a little cold glacial AcOH, and the ppt. dried at 150°. Crystn. from AcOH and benzene gave 0.6 g. (22% yield) brick-red platelets, m. 250°. The corresponding reactions with *o*-nitrotoluene were always neg. *2,4-Dinitrotoluene* (V) and II: 1.82 g. V, 1.5 g. II, 1.1 g. calcined Na_2CO_3 and 100 cc. alc. were refluxed for 1, 2, 3 and 5 hrs. Each reaction mixt. was concd. to 20 cc. by distn. and allowed to stand for 24 hrs. The ppts. were washed with very little alc. and then with water,

and dried. A benzene soln. contg. 0.4 g. of the crude product was analyzed chromatographically on Al_2O_3. The 2 principal zones contained the azomethine (VI) and the nitrone (VII). Heating for 1, 2, 3 and 5 hrs. gave 1.84 g. crude product (*A*), m. 176–8°; 1.65 g. crude product (*B*), m. 190–2°; 1.72 g. crude product (*C*), m. 194–203°; 1.95 g. crude product (*D*), m. 196–200°; resp. Analysis of 0.4 g. *A*, *B*, *C* and *D* for crude VI gave 0.162 g., m. 202°, 0.252 g., m. 201°, 0.253 g., m. 204°, and 0.226 g., m. 200°, resp., and for crude VII gave 0.150 g., m. 190°, 0.114 g., m. 188°, 0.044 g., m. 184° and 0.003 g., m. 192°, resp. Combination and crystn. of the samples gave VI, m. 209–10°, and VII, m. 194°. The 2 following expts. were made to det. whether VI could be formed from VII by loss of O_2: (1) 3.3 g. VII, 1.1 g. calcined Na_2CO_3 and 100 cc. alc. were refluxed for 20 hrs. The vol. was reduced to 20 cc. by distn. After cooling the ppt. was washed with water and dried, and the product treated with 50 cc. boiling benzene. Crystn. of the residue from Me_2CO gave 2.5 g. violet cryst. powder, m. 238° (decompn.). (2) 0.33 g. VII, 0.11 g. Na_2CO_3, 0.15 g. II and 10 cc. alc. were boiled for 20 hrs. The vol. was then reduced to 2 cc. Purification gave 0.16 g. violet ppt., m. 237 8°. Both violet compds. are the 2,4-dinitro-*p*-dimethylaminobenzanilide. VI was not found in the mixts. *2,6-Dinitro-4'-dimethylaminostilbene:* 1.82 g. 2,6-dinitrotoluene (VIII), 1.49 g. IV and 0.4 g. III were refluxed for 5 hrs. at 150–60°. The hot reaction mass was poured into a flask, dissolved in 20 cc. boiling glacial AcOH and allowed to stand. One crystn. from benzene and one from glacial AcOH gave 1.7 g. (55% yield) large irregular bright violet-red crystals with a dark green metallic luster, m. 139°, very sol. in Me_2CO, pyridine and $PhNO_2$, difficultly sol. in AcOH and benzene, very slightly sol. in alc. *2,6-Dinitrobenzaldehyde p-dimethylaminoanil:* 18.2 g. VIII, 5 g. II, 10.6 g. Na_2CO_3 and 200 cc. alc. were refluxed for 32 hrs., filtered hot, evapd. to 50 cc. and allowed to cool. The black cryst. mass was washed with very little cold alc., then with much water, and dried *in vacuo* over $CaCl_2$. Chromatographic analysis of the benzene soln. on Al_2O_3 gave a violet-red zone (next to lowest zone), which was extd. with Me_2CO. Evapn. of the solvent and crystn. from a mixt. of alc. and Me_2CO gave 0.4 g. (about 1% yield) small violet-red prisms with a green luster, m. 150°, easily sol. in benzene and Me_2CO, slightly sol. in alc. *2,5-Dinitrostilbene* (IX): 18.2 g. 2,5-dinitrotoluene (X), 10.6 g. BzH and 4 g. III were refluxed for 16 hrs. at 165–75°. After treatment with steam the cooled black mass was washed with MeOH, dissolved in 50 cc. hot glacial AcOH and filtered. The filtrate was reduced to 20 cc. The brown cryst. powder, which sepd. slowly on standing, was recrystd. from glacial AcOH and from alc., giving 4.5 g. (16% yield) small brown needles, m. 149.5°, readily sol. in cold benzene and Me_2CO and in hot AcOH, moderately sol. in alc. *2,5-Dinitrostilbene dibromide* (XI): 2.7 g. IX was dissolved in glacial AcOH, 1.6 g. Br_2 added dropwise with shaking, the mixt. heated for 20 min. on a water bath and boiled for 2 min. On cooling 1.8 g. small yellow needles, m. 203–5°, sepd. Diln. of the mother liquor with water contg. a little H_2SO_3 gave 0.8 g. crude XI, m. 200°. The total yield of crude XI was 60%. Crystn. from benzene gave a fine white powder and from AcOH, small, slightly yellow needles. Pure XI, m. 220–2°, is easily sol. in cold $PhNO_2$, pyridine and Me_2CO and in hot benzene and glacial AcOH, and very slightly sol. in alc. *2,5-Dinitro-4'-dimethylaminostilbene:* 1.82 g. X, 1.49 g. IV and 0.4 g. III were refluxed for 8 hrs. at 160–70°. The warm black mass was poured into a flask, 25 cc. MeOH added, the mixt. heated to boiling and allowed to stand for 12 hrs. The ppt. was washed with MeOH and dried at 100°. Crystn. from Me_2CO and benzene gave 0.45 g. (14% yield) fine violet needles, m. 168°, fairly sol. in AcOH, Me_2CO and benzene, slightly sol. in alc. *3,4-Dinitrobenzaldehyde p-dimethylaminoanil* (XII): 18.2 g. 3,4-dinitrotoluene, 7.5 g. II, 10.6 g. Na_2CO_3 and 200 cc. alc. were refluxed for 8 hrs. After prolonged cooling, the ppt. was washed with very little alc., then with much lukewarm water, and dried at 120°. One crystn. from Me_2CO and 2 from benzene gave violet platelets (XIII), m. 220°. Analyses gave no definite information as to their nature. The Me_2CO mother liquor from XIII was reduced to half its vol. The resulting product, after 2 crystns. from Me_2CO, gave 2.8 g. XII (9% yield), dark green needles, m. 186–8°, very sol. in $PhNO_2$ and pyridine, fairly sol. (with a violet-red-brown coloration) in Me_2CO and benzene, slightly sol. in alc. *3,4-Dinitrobenzaldehyde* (XIV): 3.14 g. XII was dissolved in cold benzene and the soln. shaken with 500 cc. 15% HCl; the HCl soln. was renewed 2–3 times. The benzene layer was washed with dil. Na_2CO_3 and water, and dried over anhyd. Na_2SO_4. The solvent was distd. off, the oily residue ground with a little petr. ether and the ppt. dried on a porcelain plate. Crystn. from water and from petr. ether contg. 5% benzene gave 0.65 g. yellowish needles, m. 62.5°, readily sol. in the ordinary org. solvents except petr. ether. *Phenylhydrazone of* XIV: To a benzene soln. contg. 0.15 g. $PhNHNH_2$ and 1 drop glacial AcOH was added 0.2 g. XIV. Crystn. of the resulting ppt. from benzene gave 0.2 g. irregular violet-red crystals with a green luster, m. 184 6°, easily sol. in $PhNO_2$, pyridine and Me_2CO, fairly sol. in benzene, slightly sol. in alc.

Ruth Berggren

Simple formation of *o*-nitrosophenol from benzene and hydroxylamine by air oxidation. Preparation of *o*-nitrosophenol and nitrosocresol from benzene or toluene by hydrogen peroxide oxidation. Oskar Baudisch. *Naturwissenschaften* **27**, 768–9(1939).—Solns. of the Cu salts of nitrosophenol are prepd. as follows: A soln. of 1 g. $Cu(NO_3)_2$ and 3 g. $NH_2OH.HCl$ is made in 300 cc. H_2O, pH 1.9 (soln. A), 200 cc. of this soln. are vigorously mixed with 20 cc. C_6H_6 in the presence of air. By raising the pH to 2.2, following addn. of 0.2 g. guanidine carbonate, the blue color of the soln. changes to pink and after 1 hr. to deep red. Upon sepn. from the excess C_6H_6 and acidification with excess HCl, petr. ether will ext. green *o*-nitrosophenol. With Cu acetate instead of nitrate (1 g. with 3 g. $NH_2OH.HCl$ in 300 cc. H_2O, pH 3.78, soln. B) the same takes place upon shaking with C_6H_6 and air. The early pink soln. has pH 3.07, and upon standing will discolor in 15 min. to yellow, pH 2.85. Contd. shaking gives the same deep red soln. from which *o*-nitrosophenol can be recovered. Between pH 2.2 and 4 rapid autoxidation takes place; a higher pH gives side reactions, a lower pH decomposes the red salt. Toluene does not give nitrosocresol at pH 2.2. Shaking soln. B with C_6H_6 for some time and adding a little H_2O_2 will cause a red color to appear, deepening upon standing, due to nitrosophenol formation. Soln. A with toluene at pH 2.2 and vigorously stirred will give a red color upon addn. of H_2O_2. Acidification with HCl and extn. with petr. ether yields green nitrosocresol. **A simple method for preparation of nitrosophenols from phenol and derivatives.** Oskar Baudisch and Schuyler H. Smith. *Ibid.* 769.—Phenol (1 g.), 2 g. Cu acetate and 0.7 g. $NH_2OH.HCl$ in 100 cc. H_2O, on addn. of 2 g. H_2O_2, give a deep red soln. from which after a few days at 0° free *o*-nitrosophenol can be recovered by adding petr. ether and acidifying with HCl. The united petr. ether exts. yield 15–20% nitrosophenol. With Ni the results are less favorable; with other metals no reaction takes place. With *p*-cresol in a similar manner *p*-nitrosocresol is obtained.

Catalytic action of clays and other silicate minerals and compounds on aromatic amines and phenols. Alfred Eisenack. *Zentr. Mineral., Geol.* **1938A**, No. 10, 305–8.—A preliminary note. Clays, mixed with solid amines or suspended in liquid amines, catalyze slow reactions producing dyes and colorless by-products. The reactions, obtained with a large no. of amines and with phenol, were also catalyzed by kaolin, weathered feldspar and basalt, serpentine, pptd. Mg and Al silicates, silica gel, permutite, and $Fe(OH)_3$, but not by active C, pptd. $CaCO_3$ or cellulose. The materials which catalyze the reactions are excellent adsorbents for the dyes produced.

Michael Fleischer

Preparation and utilization of nitrosoamines. N. N. Voznesenskiĭ and B. I. Izrail'son. *Khlopchato-Bumashnaya Prom.* **1938**, No. 10, 29–33; *Khim. Referat. Zhur.* 2, No. 4, 123–4(1939).—The following amines were investigated: *m*-, *o*- and *p*-nitroaniline, 4-nitro-2-aminotoluene, 5-nitro-2-aminotoluene, 4-nitro-2-aminomethoxybenzene, 5-nitro-2-aminomethoxybenzene, 2-nitro-4-chloroaniline, dichloroaniline, chloroanisidine, 6-chloro-2-aminotoluene, 5-chloro-2-aminotoluene and 4-chloro-2-aminotoluene. For each of the mentioned amines an optimum procedure for diazotizing and for the prepn. of the nitrosoamines is given. From the investigation of the nitrosoamines the following conclusions have been reached. (1) Amines having nitro groups in the *o*- or *p*- positions to the NH_2 group very easily form the nitrosoamines in the cold. (2) Amines having Cl in the mol. change to nitrosoamines with greater difficulty and require for this a prolonged heating. (3) Amines having a NO_2 group in the *m*-position form no nitrosoamines either in the cold or on heating. Methods for the prepn. of different printing dyes (developed by V. and I.) are given. (1) From the starting material (5-nitro-2-aminomethoxybenzene) for Azo Red with different naphthols satd. hues of bordeaux, garnet, brown, yellow, black, etc., are formed. (2) From nitroaniline, fast colors of red, yellow and brown are obtained. W. R. Henn

New method of preparing α-alkyl- and α-acylphenylhydrazones and α-alkylphenylhydrazines. Panos Grammaticakis. *Compt. rend.* **209**, 994–7(1939).—Phenylhydrazones of the type PhCH:NNRPh (I), where R is alkyl or acyl, are readily prepd. by the action of an alkyl or acyl halide, RX, on the Na deriv. (II) of PhCH:NNHPh, prepd. as a white hygroscopic powder insol. in C_6H_6 or Et_2O, by acting with Na thereon in C_6H_6 or Et_2O: PhCH:NNNaPh + RX = PhCH.NNRPh + NaX. II with MeI gives I (R = Me), m. 104°, b_{18} 212 13°, which hydrolyzes with HCl to $PhNMeNH_2$. Similarly EtI, iso-BuBr, $PhCH_2Cl$, AcCl and BzCl give I with R = Et, m. 50°, b_{14} 214°; iso-Bu, b_{13} 219–20°; CH_2Ph, m. 111°; Ac, m. 122°, $b_{\text{below 1}}$ 175 6°; and Bz, m. 123°, $b_{\text{below 1}}$ 240–1°, resp. C. A. Silberrad

Mercuration of benzene and chlorobenzene. Costin D. Nenitzescu, Dimitrie A. Isăcescu and Carol Gruescu. *Bul. Soc. Chim. Romania* **20A**, 127–34(1938).—The introduction of Hg as the acetate into the C_6H_6 nucleus is reviewed briefly along with consideration of Maynard's (*C. A.* 18, 2141) proposed equil. reaction, $C_6H_6 + Hg(OAc)_2 \rightleftharpoons PhHgOAc$ (I) + AcOH, to which some exception is taken in view of the inability to duplicate the high yield through the use of EtOH for the removal of the AcOH component of the equil. and the formation of polymercurated products. The present study was accordingly directed toward ascertaining empirically the proportions of $Hg(OAc)_2$, C_6H_6 and AcOH which would give the highest yields of I; for this purpose the detn. of I in the presence of $Hg(OAc)_2$ was based upon the large difference in the solubilities of these 2 compds. in dry C_6H_6. The expts. were made with 10 g. (1/30 mol.) $Hg(OAc)_2$ using 1, 10, 20, 25, 35 and 45 mol. ratios of C_6H_6 and 5, 10, 15, 20, 30 and 40 mol. ratios of glacial AcOH, with 3, 6 and 9 hrs. of heating; the results are tabulated and indicated diagrammatically. It was observed that the larger the amt. of AcOH, the quicker the $Hg(OAc)_2$ goes into soln.; the smaller the amt. of C_6H_6 and the greater the amt. of AcOH, the greater is the amt. of polymercurated compds. The yield of I increases with excess C_6H_6 and with the AcOH up to a max. between 10–20 mols., beyond which it drops off; it also increases with time up to a max. and then declines. The optimum condition for the prepn. of I consists of warming 160 g. $Hg(OAc)_2$ with 137 g. C_6H_6 and 600 g. AcOH for 9 hrs. on the water bath, removing the excess AcOH and C_6H_6 under diminished pressure and extg. the reaction mixt. (166 g.) in a Soxhlet app., which gave a 155 g. (92%) yield of I; for conversion to PhHgCl, 100 g. of I was heated with 200 cc. 25% KCl with stirring for 5 hrs. on the water bath, yielding 98 g. of product, m. 249°. Applying this reaction to PhCl, a 50% yield of *p*-ClC_6H_4HgOAc (II) (cf. Hanke, *C. A.* **17**, 2275), m. 194°, from MeOH, was obtained, and the product was identified by converting to *p*-ClC_6H_4Br with H_2O and Br. On account of the difficulty in wetting II with H_2O it was not possible to apply the above conversion to the chloride; however, by treating 220 g. II with 500 cc. of a mixt. of 2 parts AcOH and 1 part 6% KCl soln. a 196-g. yield of *p*-ClC_6H_4HgCl (cf. Nesmeyanov and Povch, *C. A.* **28**, 6429[1]), m. 240°, from Me_2CO, was obtained.

John F. Lontz

Nitrones. VI. Synthesis of benzylideneureas. Vito Bellavita and Nerina Cagnoli. *Gazz. chim. ital.* **69**, 602–8(1939); cf. *C. A.* **34**, 1638[1].—Although RCH:N(:O)-$CONH_2$ compds. have long been known, the corresponding thio compds., which should be formed by the reaction: RHCO + $H_2N(:O)CSNH_2$ (I) → RCH:N(:O)$CSNH_2$, have not been described. Expts. were therefore undertaken to learn whether this reaction can be realized in a practical way. Since $H_2N(:O)CONH_2$ (II) is formed from HOCN (III) and NH_2OH (IV) (cf. Francesconi and Parrozzani, *Gazz. chim. ital.* **31**, II, 337(1901)), it was thought possible to prep. I from HSCN (V) and IV. The method of prepn. of F. and P. for II was utilized in the attempt to prep. I, but prolonged contact of equimol. proportions of KSCN (VI) and IV.HCl yielded no I. Therefore the reaction of aq. VI and IV.HCl was studied more fully. Both at room temp. and on a steam bath, aq. VI and IV.HCl (equimol. wts.) form S and NH_3, while the soln. contains hyposulfite, sulfite, sulfate and carbonate. Probably IV reacts in the $H_3N.O$ (VII) form, i. e., as an oxidizing agent in distinction to a reducing agent (cf. *Ber.* **29**, 2445(1896); *Rend. accad. Lincei* **10**, II, 305(1901)). The reactions would then be: V + VII → III + NH_3 + S; III + $2H_2O$ → NH_4HCO_3 or V + VII + $2H_2O$ → $(NH_4)_2CO_3$ + S. Therefore no I is formed. Further study of this reaction was postponed, and attention was turned to the reaction of VI, IV.HCl and an aldehyde. When the chief product of this reaction forms slowly, S is a by-product, the quantity of which corresponds almost to that in the VI. When the reaction is rapid, the mother liquor contains a little sulfate, much sulfite and thiosulfate. The chief products are benzylideneureas which had been obtained previously by reduction of the corresponding carbonamidic nitrones by KCN. This reaction is therefore another excellent method of synthesizing benzylideneureas in almost 100% yields. Also it makes possible the synthesis of ureides corresponding to certain hydroxylated aldehydes which cannot be prepd. from the corresponding nitrones. This synthesis is explained by the initial oxidation of V, thus: V + VII → III + S + NH_3. III then reacts thus: III + IV → II. The next reaction is: II + RCHO → RCH:N(:O)$CONH_2$ + H_2O. The nitrone then acts as an oxidizing agent, thus: 2RCH.N(:O)$CONH_2$ + S → 2RCH:N$CONH_2$ + SO_2. The synthesis was carried out by continuous grinding of 1 mol. of aldehyde, 1 mol. of VI and 2 mols. of IV.HCl in a little water (keeping cold) until the reaction was complete (usually 2–3 hrs.), and washing the product with water. The mother liquor contains the S chiefly as sulfite and hyposulfite, but also a little as sulfate, sulfide and free S; NH_3 and CO_2 are also detectable. In prepg. liquid benzylideneureas and those with low m. ps., the reaction mixt. should be allowed to stand for 18–24 hrs., then steam-distd. and the part of the distillate having no aldehyde odor recovered. The following derivs. of urea were prepd by the new method; about half had been prepd. in the earlier work by means of KCN; therefore no data are included except for the new compds.: benzylidene, 100% yield, decompd. by hot dil. alkalies; cinnamylidene, very low yield; cuminylidene; *o*-nitrobenzylidene; *m*-nitrobenzylidene; *p-nitrobenzylidene*, lustrous, m. 131°; *p-nitrobenzylideneacetyl*, m. 128°; *p-nitrobenzylidenebenzoyl*, m. 196°; *p*-chlorobenzylidene; salicylidene; anisylidene; *resorcylylidene*, pale yellow, m. 198°; *resorcylylideneacetyl*, m. 77°; *resorcylylidenebenzoyl*, m. 152°; *vanillylidene*, m. 122°; *vanillylideneacetyl*, m. 103–4°; *vanillylidenebenzoyl*, m. 152°; 3-ethoxy-4-hydroxybenzylidene; piperonylidene;

piperonylideneacetyl, m. 109° (cf. 108–9° in previous work); *p*-dimethylaminobenzylidene; *p*-dimethylaminobenzylidenecacetyl, m. 108° (cf. 180° recorded in the previous work); furfurylidene, m. 135° (cf. 132–3° of previous work). C. C. Davis

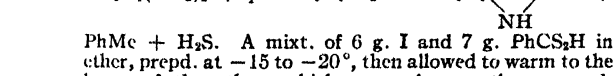
Introduction of arsenic into the aromatic nucleus by means of mercury compounds. Costin D. Nenitzescu, Dimitrie A. Isăcescu and Carol Gruescu. *Bul. Soc. Chim. Romania* **20A**, 135–8(1938).—A convenient method has been developed for the prepn. of Ph_2AsCl (I) by the action of $AsCl_3$ on PhHgCl and applied also to the prepn. of an arsphenamine intermediate, 4,3-$HO(O_2N)C_6H_3$-AsO_3H_2 (II). Thus, heating 2 mols. PhHgCl with 1 mol. $AsCl_3$ for 6 hrs. at 110°, followed by extn. with light benzine, gave 75% of I, m. 44–5°; in another expt. distn. of the product after removal of the benzine gave 8% $PhAsCl_2$ and 61% I. Treating 78 g. *p*-ClC_6H_4HgCl with 60 g. $AsCl_3$ for 8 hrs. at 110°, followed by extn. with light benzine and distn. *in vacuo*, gave 29 g. *p*-$ClC_6H_4AsCl_2$, b_{15} 142–5°. Treating 40 g. of the latter in 250 cc. H_2O with Cl to a complete soln., followed by concg. to 180° gave 63% of cryst. *p*-$ClC_6H_4AsO_3H_2$, while further concg. gave an addnl. 26%. Treating 7 g. of the arsonic acid in 27 cc. concd. H_2SO_4 with 3.5 g. $NaNO_3$ for 3 hrs. on a water bath and then, upon cooling, with 50 g. ice and 25 cc. H_2O yielded 4,3-$Cl(O_2N)C_6H_3AsO_3H_2$ (cf. Kazimierczak, *C. A.* **33**, 6263[2]), the latter (7 g.) was hydrolyzed with 25 g. 40% KOH for 10 hrs. on a water bath, treated with 12 cc. 27% HCl, decolorized with charcoal, and made acid to Congo test with HCl, which gave 65% of II.
John F. Lontz

A soluble derivative of sulfanilamide. Gualterio Seppi. *Ann. chim. farm.* (Suppl. to *Farm. ital.*) Dec., **1939**, 32–8.—*p*-$AcNHC_6H_4SO_2Cl$ reacted readily with ethanolamine to form *p*-acetylaminobenzenesulfonhydroxyethylamide, m. 124.5°. By boiling with dil. H_2SO_4 the Ac group was split off, giving *p*-aminobenzenesulfonhydroxyethylamide, $H_2NC_6H_4SO_2NHCH_2CH_2OH$, m. 98 100°, sol. in less than 10 parts water. L. E. Gilson

Color changes in phenols and in their derivatives. Ya. I. Blyakher. *Farmatsiya* **1938**, No. 5, 4–8; *Khim. Referat. Zhur.* **2**, No. 4, 122(1939).—B. observed the change of color of the ordinary and of the sterilized phenols (cryst. and liquid phenol, tricresol, Na salicylate, guaiacol, resorcinol and pyrogallol) in the pure state, in solns. and in the form of ointments, under direct and dispersed sunlight and in darkness, in the presence of O, in the absence of air, in CO_2, and under lab. and drug-store conditions. The change of color of the phenols and of their derivs. takes place more rapidly in direct sunlight than in dispersed sunlight. In darkness their colors change very little. The coloration takes place in any medium, but it is more intensive and rapid in O. Sterilization does not stop the coloration process. The intensity and the velocity of the coloration of phenols increases with the increase of their at. wt. The least coloration is observed in phenol (a yellow-brown color after keeping in direct light without any access of air). Resorcinol is more energetic in its color change (a brown-red color after 3.5 months under the same conditions) and pyrogallol has the most change of color (dark-brown color). W. R. Henn

Effect of substituents on the germicidal activity of phenols. II. Alkyl derivatives of 2,4-dichlorophenol. Szu-Liang Chien and Li-Yung Yin. *J. Chinese Chem. Soc.* **7**, 40–5(1939); cf. *C. A.* **31**, 1155[9].—$2,4\text{-}Cl_2C_6H_3OH$ is treated with an acyl chloride and the resulting oily layer, after washing with water and drying with $CaCl_2$, is distd. under reduced pressure, yielding the 2,4-dichlorophenyl ester. Four esters are prepd.: acetate, b_{80} 167–8°; propionate, b_{14} 148°; butyrate, b_{20} 161–3°; valerate, b_{16} 172°. By the Fries' rearrangement the esters are converted into the corresponding 2-hydroxy-3,5-dichlorophenyl alkyl ketones with the m. ps. indicated: Me, 95–6°; Et, 115–16°; Pr, 49–50°; Bu 46–7°. The ketones are converted by the Clemmensen reduction into the corresponding alkyldichlorophenols: Et, b_{22} 202–3°; Pr, b_{14} 136–7°; Bu, b_{11} 161–3°; Am, b_{24} 165–7°. It is suggested that the 6-alkyl-2,4-dichlorophenols should possess high germicidal activity. **III. Chlorinated hydroxyphenyl alkyl sulfides.** Szu-Liang Chien and Kuo-Tzu Chow. *Ibid.* 46–51.—**2-Chloro-4-aminophenol** (72 g.), prepd. by the method of Christiansen (*C. A.* **17**, 3865), is treated with 360 ml. dil. HCl and diazotized with 35 g. of $NaNO_2$. The mixt. is added slowly to 112 g. of Et xanthate in 350 ml. H_2O and kept at 70–75°. The xanthate ester is refluxed with 80 g. NaOH, acidified and again refluxed with Zn and C_6H_6. The oil which seps. is distd. under reduced pressure. A yield of 35 g. (43%) of 3-chloro-4-hydroxyphenyl mercaptan, b_{7-9} 108–11°, m. 39–40°, is obtained. The mercaptan is treated with the alkyl alc. in the presence of NaOH and the alkyl iodide added. The mixt. is then refluxed and extd. with C_6H_6, the C_6H_6 distd. off, and the residual oil distd. under reduced pressure. Four 3-chloro-4-hydroxyphenyl alkyl sulfides are prepd.: Me, b_{10} 130–1°; Et, b_{8-9} 128–9°; Pr, b_{10} 140–2°; Bu, b_{8-10} 145–8°. Wm. H. Adolph

Synthesis of 2-α-hydroxyethyl-4-(hydroxymethyl)anisole and some of its derivatives. Maurice Anglade. *Compt. rend.* **210**, 52–5(1940).—2,4-$MeCHCl(ClCH_2)$-C_6H_3OMe (I) is prepd. by satg. at 15° with HCl a well agitated mixt. of 156 g. anisyl chloride, 50 g. paraldehyde, 100 g. concd. HCl and 50 g. H_3PO_4. The product is washed and poured into a soln. of NaOMe in MeOH; on distn. 110 g. *p*-methoxymethylanisole, b_{15} 107–8°, and 38 g. *2-α-methoxyethyl-4-methoxymethylanisole* (II), b_{15} 144–5°, n_D^{20} 1.5055, d_4^{20} 1.048, d_0 1.066, are obtained. If NaOEt in EtOH replaces the NaOMe in MeOH the result is 120 g. *p*-ethoxymethylanisole, b_{18} 119–20°, and 35 g. *2-α-ethoxyethyl-4-ethoxymethylanisole*, b_{18} 157–8°, n_D^{25} 1.4980, d_4^{24} 1.011, d_0 1.029. II treated with AcCl in petr. ether in the presence of $ZnCl_2$ gives I. This is poured into a soln. of fused NaOAc in AcOH forming the diacetate, which is pptd. on addn. of H_2O, and is sapond. by 40% KOH in aq. EtOH at 100°. The alc. is distd. off and the aq. soln. concd. and allowed to cool when the glycol, *2-α-hydroxyethyl-4-(hydroxymethyl)-anisole*, crystallizes out; purified by recrystn. from EtOH, it forms small needles, m. 126°. On treatment with PhNCS in C_6H_6 with a trace of Na the double phenylurethan is obtained as needles, m. 142–3°. Oxidized with $KMnO_4$ it gives *p*-methoxyisophthalic acid. The presence of a small amt. (10%) of *o*-methoxybenzyl chloride in the anisyl chloride has no effect. C. A. Silberrad



The constitution of celastrol. II. O. Gisvold. *J. Am Pharm. Assoc.* **29**, 12–14(1940); cf. *C. A.* **33**, 7305[8].—Celastrol, a red pigment found in the outer bark of the root of *Celastrus scandens*, has the formula $C_{22}H_{30}O_3$. The mol. contains an OH group sufficiently acidic to be methylated by CH_2N_2. The remaining 2 O atoms seem to be present in the form of an *o*-quinone which can be reduced catalytically and reoxidized by atm. O.
A. Papineau-Couture

Condensation of aldehydes with amides. IV. *m*-Hydroxybenzaldehyde. Rup Kishore Mehra and Kantilal C. Pandya. *Proc. Indian Acad. Sci.* **10A**, 279–81 (1939); cf. *C. A.* **33**, 8589[6].—*m*-HOC_6H_4CHO, heated several hrs. on the water bath with $EtCONH_2$, $BzNH_2$ and $PhCH_2CONH_2$, gives the corresponding (*m*-hydroxybenzylidene)amides. The best yield is obtained with 1 mol. aldehyde/2 mols. amide. In contrast to the behavior of salicylaldehyde (cf. *C. A.* **32**, 7434[2]) the yield is not improved by the presence of traces of org. bases like pyridine. No condensation takes place with $HCONH_2$ and $AcNH_2$. *(m-Hydroxybenzylidene)propionamide*, m. 210°, yield 27.5%. *(m-Hydroxybenzylidene)benzamide*, m. 205°, yield about 58%. *(m-Hydroxybenzylidene)-phenylacetamide*, m. 190°, yield 40%. **V. *p*-Hydroxybenzaldehyde.** Mohammad Manzur and Kantilal C. Pandya. *Ibid.* 282–4.—*p*-HOC_6H_4CHO, heated for 4–5 hrs. with $HCONH_2$, $AcNH_2$, $EtCONH_2$, $BzNH_2$ and $PhCH_2CONH_2$ at 130–40°, gives the corresponding (*p*-hydroxybenzylidene)amides in very good yield. In contrast with the behavior of salicylaldehyde (*C. A.* **32**, 7434[2]) the yield is only slightly improved by the presence of traces of org. bases like pyridine. The products are more or less yellow powders. *(p-Hydroxybenzylidene)-*

formamide, decomp. 216° (yield 60–3%); (*p-hydroxybenzylidene*)*acetamide*, does not m. till 340° but decomp. (yield 87.5–92%); (*p-hydroxybenzylidene*)*propionamide*, decomp. 195° (yield 82–4%); (*p-hydroxybenzylidene*)*benzamide*, becomes dark red at 190°, swells at about 215° (yield 81–3%); (*p-hydroxybenzylidene*)*phenylacetamide*, does not m. 340° but decomp. (yield 80–1%). VI. *o-*, *m-* **and** *p*-**Methoxybenzaldehydes.** Rup Kishore Mehra and Kantilal C. Pandya. *Ibid.* 285–8.— *o-*, *m-* and *p*-$MeOC_6H_4CHO$ heated several hrs. with $AcNH_2$, $EtCONH_2$, $BzNH_2$ and $PhCH_2CONH_2$ at 100–40° give the corresponding (methoxybenzylidene)bisamides, $MeOC_6H_4CH(NHR)_2$, in 37–58% yield, thus differing from *o-*, *m-* and *p*-HOC_6H_4CHO which all form (hydroxybenzylidene)amides, $HOC_6H_4CH{:}NR$. The $MeOC_6H_4CHO$ do not condense with $HCONH_2$. (*o-Methoxybenzylidene*) *derivs.*: *bisacetamide*, m. 223°; *bispropionamide*, m. 196–7°; *bisbenzamide*, m. 233°; *bis*(*phenylacetamide*), m. 197°. (*m-Methoxybenzylidene*) *derivs.*: *bisacetamide*, m. 206°; *bispropionamide*, m. 201°; *bisbenzamide*, m. 201–2°; *bis*(*phenylacetamide*), m. 181–2°. (*p-Methoxybenzylidene*) *derivs.*: *bisacetamide*, m. 230–1°; *bispropionamide*, m. 228°; *bisbenzamide*, m. 223–4°; *bis*(*phenylacetamide*), m. 243°. *p*-$MeOC_6H_4CHO$ yields with $HCONH_2$ a small amt. of pale-yellow crystals, m. about 171°. Dora Stern

A new adrenal base. J. J. Pfiffner and H. B. North. *J. Biol. Chem.* **132**, 461–2(1940).—A new phenolic base has been isolated from cattle adrenal glands for which the name *andrenodiamine* is suggested. It is the only phenolic amine other than adrenaline thus far isolated in pure form from the adrenal gland. *Andrenodiamine*, m. 219–21° (decompn.), min. mol. wt. 216; *O-Ac deriv.*, m. 176–7° (decompn.); *mono-Me ether*, m. 132–3° (decompn.); *di-HCl salt*, sinters at 195°, m. 215–16° (decompn.). All m. ps. are uncor. It has no pressor or oxytocic activity. Adrenodiamine has absorption max. at 231, 271 and 300 mμ and min. at 248, 290 and 360 mμ.
A. P. Lothrop

Cleavage of the acid group in carbodithioic acids. H. Wuyts and J. van Vaerenbergh. *Bull. soc. chim. Belg.* 48, 329–39(1939).—The reaction analogous to decarboxylation has been effected with (aromatic) carbodithioic acids and certain basic products. Thus, with *o*-$C_6H_4(NH_2)_2$ (I) carbodithioic acids gave a mixt. of the substituted benzimidazoles, corresponding to a reaction of the intact acid, and benzimidazolethiol (II), by the reaction, e. g., with *p*-toluenecarbodithioic acid (III):

PhMe + H_2S. A mixt. of 6 g. I and 7 g. $PhCS_2H$ in ether, prepd. at −15 to −20°, then allowed to warm to the b. p. of the ether, which was subsequently removed, yielded phenylbenzimidazole (about 55%), m. 288°, and II, m. 292°. Similarly, 10.8 g. I in 40 cc. ether and 20 g. α-$C_{10}H_7CS_2H$ (IV) in an equal vol. of ether gave 17 g. (71%) α-naphthylbenzimidazole, m. 271°, and a small amt. of II. III (8.4 g.) and 6 g. I yielded PhMe (identified by n_D^{25} (1.4950) and by the 2,4-dinitro deriv.), 60% *p*-tolylbenzimidazole, m. 265°, and II. III (11 g.) and 12 g. benzidine gave 5 cc. of PhMe, thiocarbonylbenzidine, $H_2NC_6H_4C_6H_4NCS$, m. 187°, and a substance identical with the dithioöxamide, $[H_2NC_6H_4C_6H_4NHC(:S)]_2$, of Cecchetti and Sarti (*C. A.* **23**, 3444). IV and benzidine gave an incomplete reaction in boiling ether, but in boiling C_6H_6, using 8 g. and 10 g., resp., of the components, $C_{10}H_8$, 62.5% of thiocarbonylbenzidine, and 28% of the dithioöxamide deriv. were obtained. *Thioacylated derivs.* were obtained from III and the following bases: $PhNH_2$, m. 144°; *m*-$C_6H_4(NH_2)_2$, (mono deriv.) m. 173°; *p*-$Me_2NC_6H_4NH_2$, m. 151° (obtained along with an *anil*, m. 145°); *m*-$O_2NC_6H_4NH_2$, m. 154°. Results are tabulated.
John F. Lontz

Soluble salts of acetylsalicylic acid and their hydrolysis. J. H. Křepelka and J. Pavlíček. *Collection Czech. Chem. Commun.* **11**, 325–44(1939).—The following salts of acetylsalicylic acid (I) were prepd. by reaction with the appropriate carbonate in H_2O and MeOH: (the compd. prepd. in H_2O is given first) $2C_9H_7O_4Li.H_2O$ (II), $C_9H_7O_4Li$; $C_9H_7O_4Na$ (III); $C_9H_7O_4K.2H_2O$ (IV), $C_9H_7O_4K$; $C_{18}H_{14}O_8Mg.3H_2O$ (V), $C_{18}H_{14}O_8Mg$; $2C_{18}H_{14}O_8Ca.7H_2O$ (VI), $C_{18}H_{14}O_8Ca.2H_2O$; $2C_{18}H_{14}O_8Sr.7H_2O$ (VII). II m. 126.5° and is stable in air; III and IV are hygroscopic and m. 217.5 and 65°, resp. V and VII are stable in air; VII begins to decomp. at 115°. The m. p. of V, VI and VII cannot be detd. because of apparent decompn. *Tetramethylammonium acetylsalicylate* (VIII), which is prepd. by concn. of a mixt. of aq. solns. of I and Me_4NOH, is anhyd., unstable, hygroscopic and very sol. in H_2O, alc. and Et_2O. VIII softens at 112° and m. 120° (partial decompn.). Hexamethylenetetramine acetylsalicylate (IX) is a hygroscopic salt which m. 118–19° and which liberates CH_2O upon exposure to light. The amt. of CH_2O thus produced is dependent on the temp. and H-ion concn. The course of hydrolysis of aq. solns. of all the above salts except VIII was studied at 60° by detn. of AcOH at regular intervals. The stability of the salts prepd. in nonaq. media was somewhat greater than that of the same salts prepd. in H_2O. The work confirms the conclusion that the sol. salts of I are the more unstable the more pos. is their cation. David E. Adelson

Lichen pigments of the pulvinic acid series. VI. Synthesis of atromentinic acid. Mitizo Asano and Sinobu Huziwara. *J. Pharm. Soc. Japan* 59, 675–9(in German, 284–6)(1939); cf. *C. A.* 29, 7309[3]; 33, 5838[4].—*p,p'*-Dimethoxydiphenylketipinonitrile (I) (Kögl, *et al.*, *C. A.* 23, 1128) (0.3 g.) in 15 cc. glacial AcOH, when refluxed over the flame with HI, gave atromentinic acid, $C_{18}H_{12}O_7.H_2O$, m. 330–2°; atromentinic lactone, $C_{18}H_{10}O_6$, m. 342–6°; diacetylatromentinic lactone, m. 270–1°. I (2 g.) in 40 cc. glacial AcOH and 24 cc. 60% H_2SO_4, on refluxing over the flame, gave 2 g. crude *p,p'*-dimethoxypulvinic anhydride (II), m. 266–8°; the Et ester, $C_{22}H_{20}O_7$, m. 155–7°; *p,p'*-dimethoxypulvinic acid, $C_{20}H_{16}O_7.H_2O$, m. 212°. II (0.2 g.) in 40 cc. glacial AcOH and 8 cc. HI on refluxing as before gave 0.1 g. atromentinic acid, m. 330–2°. **VII. Reduction of vulpinic acid.** Mitizo Asano and Yosio Arata. *Ibid.* 679–87(in German, 286–90); cf. *C. A.* 29, 7309[2].—Reduction of 10 g. vulpinic acid with 1% Na-Hg gave the following compds.: compd., m. 67° (yield 0.25 g.), which did not depress the m. p. of Me dihydrocornicularate, and the other dihydrovulpinic acid (I), $C_{18}H_{12}O_4(OCH_3)_2$, m. 194–6° (yield 6 g.). I forms the benzoate, m. 138–9°, and isodihydrovulpinic acid, $C_{18}H_{12}O_4(OCH_3)_2$, m. 123–7°. Hydrolysis of I with $Ba(OH)_2$ gave dihydropulvinic acid (II), $C_{18}H_{14}O_5$, decompg. 208–10°. II (1 g.) in 5 cc. Ac_2O, when boiled for 15 min., gave after decompg. in glacial AcOH cornicularic lactone carboxylic acid (III) (lactone of carboxycornicularic acid), m. 218–19°; Me ester (IV), $C_{19}H_{14}O_4$, m. 170–2°. Hydrolysis of III with KOH gave cornicularic acid, m. 118–21°; semicarbazone, m. 212–14°. II (2 g.) when heated under reduced pressure gave cornicularic lactone (V), $C_{17}H_{12}O_2$, m. 136–6.5°. Reduction of IV with Na-Hg gave a neutral compd., which when hydrolyzed with $Ba(OH)_2$ gave phenylsuccinic acid, m. 166–8°, and anacidic compd. m. 139–42°, which when hydrolyzed with $Ba(OH)_2$ gave phenyladipic acid, m. 247–50°. Reduction of V with Na-Hg gave a neutral compd., $C_{17}H_{16}O_2$, m. 69–71°, and an acidic compd. which was not identified. Reduction of V with Zn and AcOH gave a neutral compd., m. 90–2°, and an acidic compd., $C_{17}H_{16}O_3$, m. 133–4°, which did not depress the m. p. of dihydrocornicularic acid. Reduction of vulpinic acid with Pd-C gave dihydrovulpinic acid, m. 194–6°. Reduction of pulvinone, $C_{17}H_{12}O_3$, m. 242–3.5°, with Na-Hg gave dihydropulvinone, $C_{17}H_{14}O_3$, m. 215–19°; benzoate, m. 140–1°. F. I. Nakamura

The preparation of nitrogen-substituted phthalimides. Gustav Vanags. *Acta Univ. Latviensis, Kim. Fakultat.* Ser. 4, No. 8 (in German, 405–21; in Lettish, 422)(1939). —Aniline (3.1 g.), 7.4 g. phthalic anhydride and 60 cc. AcOH, refluxed in an air condenser for 45–60 min. or until a 0.5 cc. sample boiled for 1 min. showed a yellow

or a brown color (a green color indicated the presence of unacetylated aniline), were treated with 450 cc. H_2O, brought to a boil and cooled. Overnight the yield of $C_6H_4(CO)_2NPh$ was 95.8%; recrystd. in AcOH, it m. 208°. In a 2nd method 1 mol. aniline-HCl, 2 mols. phthalic anhydride, 1.1 mol., AcONa and 40 mols. AcOH were refluxed in an air condenser for 50 60 min., treated with 200 cc. H_2O, brought to a boil and cooled. Using either method V. prepd. the following *N-arylphthalimides:* *o*-tolyl, from *o*-toluidine, m. 183°, sol. in EtOH and AcOH, formed needles in EtOH; *m*-tolyl, m. 176°, sol. in EtOH and AcOH, formed pearly plates from AcOH; *p*-tolyl, m. 204°, sol. in EtOH and AcOH, formed glistening needles from EtOH; 2-ethylphenyl, from *o*-ethylaniline, m. 137°, sol. in EtOH and AcOH, formed long plates from EtOH; 4-ethylphenyl from *p*-ethylaniline, m. 177°, more sol. than the *o*-compd., formed silky needles from EtOH and AcOH; 2,4-dimethylphenyl, from *m*-xylidine, m. 155°, formed hexagonal plates; 2,5-dimethylphenyl, from *p*-xylidine, m. 163°, sol. in EtOH and AcOH. 2,6-Dimethylphenyl, from 1,3,2-xylidine, m. 204°, sol. in AcOH and slightly sol. in EtOH, formed hexagonal plates from EtOH; 3,5-dimethylphenyl, from 1,3,5-xylidine, m. 135°; 2,4,6-trimethylphenyl, prepd. from mesidine, m. 171°; 2,4,5-trimethylphenyl, from pseudocumidine, m. 147°; *o*-biphenylyl, from *o*-$H_2NC_6H_4Ph$, m. 165°, from $PhNO_2$; *m*-biphenylyl, from *m*-$H_2NC_6H_4Ph$, m. 154°, formed long, soft needles from AcOH, sol. in EtOH with difficulty; *p*-biphenylyl, from *p*-$H_2NC_6H_4Ph$, m. 285°, from $PhNO_2$, sol. with difficulty in AcOH; 4-triphenylmethylphenyl, from *p*-$H_2NC_6H_4CPh_3$, m. 247°, from AcOH; α-naphthyl, from α-naphthylamine, formed plates in AcOH, m. 181°; β-naphthyl, m. 216°, from AcOH; α-tetrahydronaphthyl, from tetrahydro-α-naphthylamine, sol. in EtOH and AcOH, formed needles in EtOH, m. 142°; 2-fluorenyl, from 2-aminofluorene, m. 288°, from $PhNO_2$; 4-acetoaminophenyl, m. 283°, from AcOH; 4-anilinophenyl, from *p*-$H_2NC_6H_4CH_2Ph$, formed green-yellow fine needles from AcOH, m. 270°; 4-dimethylaminophenyl, formed yellow needles in AcOH, m. 260°; 4-phthalimidoazobenzene, prepd. from *p*-aminoazobenzene, formed yellow needles in AcOH, m. 252°. 2-Phthalimidopyridine formed glossy needles in EtOH, m. 226°. *N-Alkylphthalimides:* Me, prepd. from $MeNH_2$, formed long needles in dil. AcOH, m. 134°; Et, m. 78°, formed long (10–15 cm.) fine needles in dil. AcOH; iso-Pr, m. 86°, from AcOH; Bu, m. 34°, iso-Bu, m. 93°, from EtOH; heptyl, m. 40°, from dil. EtOH; heptadecyl, m. 63°, from AcOH. Other *N*-derivs are: allyl, formed thin platelets from dil. AcOH, m. 70°; benzyl, m. 115°, from EtOH; α-phenethyl, prepd. from $PhCHMeNH_2$, m. 43–4°, from EtOH; β-phenethyl, m. 130°, formed pearly scales in EtOH, sol. in AcOH; benzohydryl, m. 225°, from AcOH, formed isomers of isoquinoline compds.; β-tetrahydronaphthylphthalimide, m. 128°, formed needles in EtOH, sol. in AcOH; cyclohexyl, m. 168° from EtOH; camphyl, m. 55°, from AcOH. Unless specified AcOH means glacial AcOH. Frank Maresh

Preparation of mellitic acid. Ettore Vallesi. *Ann. chim. applicata* **29**, 455–63(1939).—By use of the best of the modern charcoals very pure mellitic acid was prepd. with fairly high yields. A. W. Contieri

Constitution of two new terpenes, menogene and menogerene ($C_{10}H_{16}$ and $C_{10}H_{14}$). The mechanism of cyclization of citronellal and citral. Riki Horiuti, Hirosi Otuki and Osamu Okuda. *Bull. Chem. Soc. Japan* **14**, 501 7 (1939)(in English).—The constitution of the cyclic terpenes $C_{10}H_{16}$ (I) and $C_{10}H_{14}$ (II) obtained by the action of H_2SO_4 on *citronellal* (III) and *citral* (IV), resp. (cf. *C. A.* **22**, 3886), has been established. I is now named *menogene* and II *menogerene*. I, from III with 50% H_2SO_4, $b_{764.5}$ 184–6°, d_4^{20} 0.8624, n_D^{20} 1.5026, $[\alpha]_D^{18}$ 49.11°, $[R_L]_D$ 46.59 (calcd. for $C_{10}H_{16}$ 45.24); *nitrosite*, scales from MeOH-$CHCl_3$, m. 154.5–5.0°, $[\alpha]_D^{20}$ −174.06°. I, reduced with H in EtOH in the presence of Pd oxide, gives *p*-menthane (V). I absorbs only 1 mol. Br. I, warmed with an equiv. amt. of maleic anhydride in C_6H_6 or Et_2O, gives a *solid* (VI), m. 205–8°, $[\alpha]_D^{25}$ −18.76° (in Me_2CO); by treating VI with 30% KOH a *cryst. powder*, m. 228–30°, is formed, which yields a *dibromide*, m. 282–5°. The dropwise addn. of HCl to a mixt. of I with EtONO in glacial AcOH produces at low temp. a deep blue color which changes to green, yellow, deep red, and brown with rising temp. On distn. with Na I yields small amts. of Me_2CO. From the phys. and chem. behavior it is concluded that I is a *p*-menthadiene contg. 2 conjugated double bonds, 1 of which is semicyclic. This leads to the formula $Me_2C{:}CH{:}CH{:}CH.CHMe.CH_2.CH_2$. By treating IV with 20% H_2SO_4 are obtained Me_2CO, Me_2CHOH (formed by the reduction of Me_2CO in the course of distn. with Na), *1-methyl-1,5-cyclohexadiene* (b_{760} 110 11°, d_4^{20} 0.8451, n_D^{20} 1.4783, unstable in air, decomp. explosively by distn., adds 2 mol. H in the presence of Pd oxide, is oxidized by $KMnO_4$ to succinic acid), *p*-cymene (VII) and II, b_{760} 180 1°, d_4^{20} 0.8672, n_D^{20} 1.5005, $[R_L]_D$ 45.66 (calcd., 44.78 for $C_{10}H_{14}$). II gives in glacial AcOH a *dibromide*, m. 114.5–15°. II is unstable; by distn. after long standing or by treatment with 20% H_2SO_4 it changes into the isomeric VII. With EtONO and HCl II gives the same color reactions as I. On distn. with Na II yields Me_2CO. By hydrogenation of II in the presence of Pd oxide are formed *dl*-α-phellandrene and small amts. of V. From the foregoing properties it is concluded that II has the formula $Me_2C\,C.CH{:}CH.CMe\,CH.CH_2$. The constitution proved for I agrees with the formeryl found formation of isopulegol and menthoglycol as intermediates in the transformation of III into I. In the transition of IV into II (and finally into VII) dehydroisopulegol and menthoglycerol are assumed to be intermediates. Dora Stern

Contact isomerization of menthene. N. D. Zelinskiĭ. *Compt. rend. acad sci. U. R. S. S.* **24**, 542–4(1939)(in English).—3-*p*-Menthene, prepd. by dehydration of *l*-menthol over SiO_2 gel at 325°, was isomerized over SiO_2 gel at 375°, 400° and 450°, resp. After fractionation of the products, with or without the presence of Na, the main fractions were hydrogenated over Pt-charcoal at 165 70°, and the resulting materials dehydrogenated over Pt-charcoal at 300°. The products were treated with fuming H_2SO_4 (5% SO_3) to eliminate *p*-cymene and then distd. over Na, resulting in unidentified $C_{10}H_{20}$ mixts. (probably cyclopentane derivs.) having b. ranges of 154.5 162° under 746–751 mm., n_D^{20} 1.4301–1.4308 and d_4^{20} 0.7811–0.7830. In each case, unsatd. acyclic hydrocarbons were also formed during the isomerization of 3-*p*-menthene over SiO_2 gel. Passage of the $C_{10}H_{20}$ mixt. over Pt-SiO_2 gel at 300° yielded (after fuming H_2SO_4 treatment and distn. over Na) a mixt. of isomeric decanes together with lower members of the alkane series. George Ayers

Reactions of 2,2′-diacylbiphenyls. The reaction between 2,2′-diacylbiphenyls and ethylmagnesium bromide. Edith Ju-Hua Chu. *J. Chinese Chem. Soc.* **7**, 24 6 (1939); cf. *C. A.* **29**, 5108[2].—To the Grignard reagent prepd. from 0.02 mole EtBr and 0.04 mole Mg in 20 ml. ether is added 1.8 g. (*o*-$BzC_6H_4)_2$. The mixt. is refluxed for 2 hrs., hydrolyzed with ice water and AcOH and extd. with a mixt. of ether and benzene. On recrystg. from acetone, *2,2′-bis[(hydroxyethylphenyl)methyl]biphenyl*, m. 221.7 2.7°, is obtained. In a similar way 4 other new *2,2′-bis[(hydroxyethylaryl)methyl]biphenyls* are synthesized, the aryl groups being *p*-biphenylyl, *m*-tolyl, *p*-chlorophenyl and *p*-phenetyl, with the m. ps. 183.6–4.6°, 156.3–7.3°, 228.5–9.5°, 135–6°, resp. Wm. H. Adolph

Diarylmethane derivatives VI. Occurrence of the bis(4-methoxyphenyl)methyl radical. W. Th. Nauta and D. Mulder. *Rec. trav. chim.* **58**, 1062–9(1939)(in English); cf. *C. A.* **33**, 7769[1].—Treatment of (*p*-MeO-$C_6H_4)_2CHCl$ (I) (Bergmann and Hervey, *C. A.* **23**, 3918) with mol. Ag gave a red soln. from which colorless crystals of (*p*-$MeOC_6H_4)_2CH_2.C_6H_6$, m. 190–1°, sepd. quant. from C_6H_6 (cf. Bergmann and Fujise, *C. A.* **25**, 942, who report

189–90°). This showed that dimerization rather than disproportionation had occurred. When O was present, (p-$MeOC_6H_4)_2CO$ (II), m. 143–4°, was isolated. From 470 mg. of I, 386 mg. of II was formed; *2,4-*$(NO_2)_2C_6H_3NHNH_2$ *deriv.* m. 199–200°. A small amt. of p-MeC_6H_4CHO (III) was isolated by steam distn.; 2,4-$(NO_2)_2C_6H_3NHNH_2$ deriv., m. 250–1° (cf. Brady, *C. A.* **25**, 3319). In a typical expt. 17.1 millimols. of I gave 9.3 millimols. of II, 0.8 of III and 0.5 of p-$MeOC_6H_4OH$ (not definitely identified). Addn. of NO gave similar but less well-defined results. **VII. Properties of the diphenylmethyl radical.** *Ibid.* 1070–80.—The poor yield of $(Ph_2CH)_2$ (I) obtained by Montagne and others (*Rec. trav. chim.* **25**, 488(1906)) on treatment of Ph_2CHCl (II) with Ag was due to the action of O. When O is excluded, the yield is quant. In pure O, the yield is 2 8%, together with $(Ph_2CH)_2O$ (III), Ph_2CO (IV), Ph_2CHOH (V) and Ph_2CH_2. An atm. of NO gave III and IV with undefined products. A pale yellow color was observed in the reaction between II and Ag. Whether the radical is colored (cf. Gilman and Kirby, *C. A.* **20**, 2323) and present in very small amt. or is not highly colored is uncertain. In a typical expt. 6.651 g. of II with Ag absorbed 206.8 cc. of O (S. T. P.) and gave 1.197 g. of IV and 0.31 g. of V in the steam distillate, and 2.87 g. of III and 0.43 g. of $(Ph_2CH)_2$ in the residue. W. F. Bruce

Abnormal acetoacetic ester synthesis. II. Reaction of sodium with fluorene and benzyl benzoate. Heou-Fco Tseou and Tse-Shui Chow. *J. Chinese Chem. Soc.* **7**, 27 8(1939); cf. *C. A.* **32**, 5302.—$PhCH_2OBz$ (30 g.), 20 g. of fluorene and 3.5 g. Na are refluxed at 170–90° for 13 hrs. Ice water is added, the mixt. filtered and the residue is washed and recrystd. from toluene, giving 74% of benzylfluorene instead of the expected Bz compd.

Wm. H. Adolph

Nitrogen heterocycles. XLV. Nitrosation of primary amines. (Diaminoisophthalaldehyde. 3.) 4,5,6-Triaminoisophthalaldehyde and its condensations. Paul Ruggli and Hugo Frey. *Helv. Chim. Acta* **22**, 1403 12(1939); cf. *C. A.* **33**, 8608⁴.—Although diazotization of 4,6-diaminoisophthalaldehyde (I) in concd. H_2SO_4 is possible to the extent that it can be demonstrated qualitatively by coupling with β-$C_{10}H_7OH$, the reaction with $NaNO_2$ in chilled concd. HCl is of more practical interest. A mixt. of 8 g. I and 80 cc. concd. HCl at −10 to −15° was stirred and treated with 7 g. $NaNO_2$ in 15 cc. H_2O over a period of 10 mins. After 5 mins. addnl. stirring, the mixt. was poured into 1.5 l. H_2O and filtered off, yielding 8 g. (85%) of *5-nitroso-4,6-diaminoisophthalaldehyde* (II), $C_8H_7N_3O_3$, m. 260–73° (decompn.), condensing with p-$MeC_6H_4NH_2$ in AcOH to coppery leaflets of the corresponding *dianil*, $C_{22}H_{21}N_5O$, converted into violet-black needles by recrystn. from AcOEt and cleaved by hot HCl to the original II. Reduction of the deep-violet soln. of 8 g. II in 125 cc. concd. HCl by addn. of 30 g. $SnCl_2$ and working by neutralization, extn. with acetone and recrystn. from H_2O gave 60% of long, faintly beige-colored needles of 4,5,6-triaminoisophthalaldehyde (III), $C_8H_9N_3O_2$, m. 200.5° (decompn.); *mono-Ac deriv.*, m. 293° (also prepd. by catalytic reduction of II in the presence of Raney Ni catalyst); *benzal deriv.*, m. 154–6°; *dioxime*, m. 254°. Alk. condensation of III with excess AcPh gave cm.-long red needles of linear *2,7-diphenyl-9-aminobenzodipyridine*, $C_{24}H_{17}N_3$, m. 224–5°, and similarly with excess $AcCH_2CO_2Et$ produced carmine-red needles of the corresponding *3,6-dicarboxylate* (IV), $C_{20}H_{21}N_3O_4$, m. 160°; *mono-Ac deriv.*, $C_{22}H_{23}N_3O_5$, m. 234° (decompn.). Sapon. of IV yielded the free dicarboxylic acid, $C_{16}H_{13}N_3O_4$, m. 318° (decompn.), which was decarboxylated by subliming from BaO and Cu powder at 350–400° to 2,7-dimethyl-9-aminobenzodipyridine. The mother liquors from the crystn. of IV also yielded yellow crystals of a *condensation product*, $C_{14}H_{17}N_3O_4$, m. 201.5°, formed by the loss of 1 mol. H_2O from the addn. of 1 mol. III and 1 mol. $AcCH_2CO_2Et$. Diazotization of 0.2 g. IV in 5 cc. of chilled concd. HCl by the addn. of 2.8 cc. of 2% $NaNO_2$, salting out with 40 cc. of 20% AcONa and crystn. from alc. or hot dioxane gave 0.2 g. of a yellowish *trisazolium hydroxide*, $C_{20}H_{20}N_4O_5$, m. 195° (decompn.). III has 3 NH_2 groups in vicinal positions and consequently gives good yields of a *quinoxaline deriv.*, $C_{22}H_{18}N_8O_2$, m. 289–90° (decompn.), by condensation with Bz_2 in alc. in the presence of 10% NaOH in MeOH. Similarly, condensation with phenanthrenequinone gives a difficultly-sol. compd. **XLVI. 4,6-Diaminoisophthalaldehyde. 3.** *Ibid.* 1413 27.—The 3,6-dicarboxylic ester produced by the addn. of 2 mols. $AcCH_2CO_2Et$ to 4,6-diaminoisophthalaldehyde (I) was sapond. to the free acid which was decarboxylated by heating with Cu in quinoline at 160–230° for 20 min. The resulting 2,7-dimethylbenzodipyridine (II) was converted into the hexa-Br deriv. which was transformed by heating with oleum to the crude benzodipyridine-2,7-dicarboxylic acid (III). A mixt. of 0.25 g. III, 2 cc. of 10% NH_4OH and 2 cc. alc. was triturated, dild. with 20 cc. H_2O and heated. The NH_3-free product was dild. with 10 cc. H_2O and boiled with 0.5 g. $AgNO_3$ in 10 cc. H_2O. The crude Ag salt (0.45 g.) was boiled with 70 cc. MeOH and 0.4 g. MeI for 1 hr., filtered and concd. to 20 cc., yielding 0.2 g. (70%) of yellow needles of *di-Me benzodipyridine-2,7-dicarboxylate*, $C_{16}H_{12}N_2O_4$, m. 272° (with darkening). Decarboxylation of III gave benzodipyridine (IV); *perchlorate*, m. 268° (explosive on rapid heating); *MeI deriv.*, m. above 200° (decompn.). Reduction of 0.2 g. IV in 5 cc. of boiling AmOH with 0.35 g. Na and recrystn. from alc. gave octahydrobenzodipyridine, m. 111.5°, identified through the di-NO and di-Ac derivs., m. 179° (decompn.) and 143°, resp. Reduction of II with Na in AmOH gave as main product a resin which was converted into a colorless cryst. *octahydro-2,7-dimethylbenzodipyridine diperchlorate*, $C_{14}H_{22}Cl_2N_2O_8$, m. 285–6° (decompn.). The resinous free base yielded 2 isomeric *di-NO derivs.*, m. 164.5 and 151.5 2.0°, resp. Condensation of 0.2 g. II with 0.5 g. of p-$Me_2NC_6H_4CHO$ at 170–5° in the presence of 10 drops of piperidine produced 0.45 g. of orange-red *2,7-bis(p-dimethylaminostyryl)benzodipyridine*, $C_{32}H_{30}N_4$, m. about 340° (with darkening), dissolving in HCl to give violet, blue, green and yellow solns. with increasing acid concns. Condensation of II with o-$C_6H_4(CO_2Et)_2$ by heating in the presence of Na for 14 hrs. at 100° gave a scarlet cryst. powder which on sulfonation dyed wool and silk bluish red in an acid bath. A unilateral condensation of 0.6 g. I with 6 cc. $AcCH_2CO_2Et$ occurred on heating in the presence of 9 drops of piperidine for 30 min. at 170°. The impure *3-acetyl-6-formyl-7-aminocarbostyril* yielded yellow crystals of a pure *Ac deriv.*, $C_{14}H_{12}N_2O_4$, m. 320–40° (decompn.). Treatment of 1 g. I in 100 cc. alc. at 30° with 14 g. of dry $OHCCHNaCO_2Et$, boiling for 1 hr. after standing for 3 days, filtering off the brown amorphous ppt. (V), adding 1 cc. H_2O and standing for 8 days gave a Na salt which was dissolved in 50 cc. H_2O, acidified with 10% HCl and recrystd. from dioxane, yielding *di-Et 2,6-diaminoisophthalaldiformylacetate*, $C_{18}H_{20}N_2O_6$, m. 250° (decompn.). V was dissolved in H_2O, filtered and pptd. with dil. HCl. The amorphous product (0.06 g.) was decarboxylated by heating *in vacuo* with 0.3 g. BaO and 0.5 g. Cu at 150° to yield a bright yellow sublimate of IV. Condensation of I with excess cyclohexanone in the presence of piperidine produced *2,3,6,7-bis(tetramethylene)-benzodipyridine*, $C_{20}H_{20}N_2$, m. 250–1° (with darkening); *dipicrate*, m. 195° (decompn.). A mixt. of 8 g. I in 150 cc. alc., 24 cc. $PhCH_2CN$ and 12.5 cc. of 30% NaOH was heated for 30 min. on the steam bath. Working up and purification through the di-HCl salt gave a free *base* (VI), $C_{24}H_{18}N_4$, m. 301°; *tetra-Ac deriv.*, $C_{32}H_{26}N_4O_4$, m. 238.5–9.5° (decompn.). Sapon. of VI with HCl produced a *carboxyl deriv.*, $C_{24}H_{18}N_2O_3$, which gave a Na salt and a *mono-Ac deriv.*, m. 365°. Condensation of 4 g. of 4,6-dinitroisophthalaldehyde with 8.4 g. of dry $PhCH(Na)CO_2H$ by heating with 34 cc. Ac_2O and 1.2 g. $ZnCl_2$ for 40 hrs. at 80° gave a powdery dicarboxylic acid which was esterified through the Ag salt to *di-Me 4,6-dinitroisophthalate* (*phenylacetate*), $C_{36}H_{30}N_2O_8$, m. 152.5–3.5°. Condensation of methazonic acid (VII) with o-$H_2NC_6H_4CHO$ yields 3-nitroquinoline and similarly a cold mixt. of VII and I in the presence of a min. of HCl gave 20% of yellow-

orange needles of a *compd.* $C_{16}H_{14}N_6O_5$, m. 290° (decompn.), of undetermined compn. C. R. Addinall

Propionylation of the naphthols in pyridine. Alfred Léman. *Compt. rend.* **210**, 78–80(1940); cf. *C. A.* **32**, 4973⁴.—The esterification of α- and β-naphthols, 1,7-$C_{10}H_6(OH)_2$ (I) and 1,7,3-$C_{10}H_5(OH)_2SO_3H$ (II) by means of an excess of $(EtCO)_2O$ in an equal vol. of pyridine was examd. at varying temps., continuing the interaction for varying periods, the excess of anhydride being then decompd. by H_2O. With α- and β-naphthols esterification was quickly completed even in the cold, e. g., in 15 min. at 18°, and almost as quickly in the presence of H_2O from the start. Practically the same result was obtained with I, though the effect of H_2O from the start was not examd. But with II esterification is very incomplete, amounting to only 18% after 60 min. at 100°. Esterification in this way can thus be used to est. the 3 naphthols but not II. C. A. Silberrad

Synthesis of vitamin K_1. A. A. Klose and H. J. Almquist. *J. Biol. Chem.* **132**, 469–70(1940); cf. *C. A.* **33**, 8729².—Vitamin K_1 was synthesized by refluxing in the dark for 20 hrs. 1 g. of 2-methyl-1,4-naphthoquinone, 1 g. of Zn dust and 0.6 cc. of phytyl bromide in 2 cc. of glacial AcOH and 10 cc. of petr. ether. The reaction product was dissolved in hexane, repeatedly washed with H_2O, filtered and fractionated in a mol. still. The vitamin was recrystd. repeatedly from MeOH by cooling with solid CO_2. It is probable that the synthetic product contains a small amt. of cyclized vitamin K_1. A. P. Lothrop

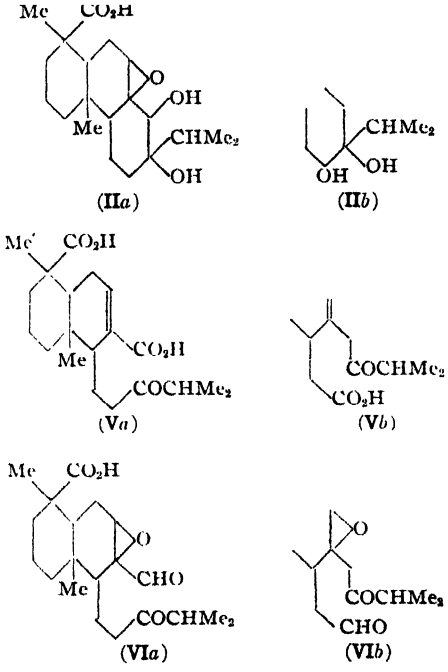
Acenaphthene series. I. 5-Benzoylacenaphthene and its related compounds. Edith Ju-Hua Chu. *J. Chinese Chem. Soc.* **7**, 14–19(1939).—5-Benzoylacenaphthene is synthesized from acenaphthene and BzCl by the method of Dziewonski and Rychlik (*C. A.* **20**, 1075⁷), but an improved yield (77%) is obtained when $PhNO_2$ is employed as solvent. By the Beckmann rearrangement, it is detd. that the oximes favor the trans form. 5-Benzoylacenaphthene reacts readily with PhMgBr to form colorless cryst. phenyl-5-acenaphthylcarbinol, m. 200.8°. Wm. H. Adolph

Retropinacolone rearrangement of 10,10-diaryl-9,10-dihydro-9-phenanthrols. Edith Ju-Hua Chu and Fan Wei. *J. Chinese Chem. Soc.* **7**, 20–3(1939); cf. *C. A.* **29**, 5108².—Two new 10,10-diaryl-9,10-dihydro-9-phenanthrols, in which the aryl groups are *p-phenetyl* and *p-chlorophenyl*, are prepd. by reduction of the corresponding 10,10-diaryl-9-phenanthrones by either Zn dust and NaOH or iso-PrMgBr; the m. ps. are 146.2° and 159.3°, resp. These 2 compds. undergo rearrangement on treatment with I and AcOH to give 9,10-diarylphenanthrenes, m. 207° and 244°, resp., the structures of which are established by oxidation. Wm. H. Adolph

Tetracinnamoylethane. J. Swiderski. *Roczniki Chem.* **19**, 142–5(1939).—Na added to dicinnamoylmethane in PhOMe, followed by I in Et_2O, gives *s-tetracinnamoylethane*, m. 230°, converted by boiling Ac_2O into *3,4-dicinnamoyl-2,5-distyrylfuran*, m. 168°. B. C. P. A.

The action of selenium on indoles, quinolines and their perhydrogenated derivatives. Sin-itiro Huzise and Kozo Tiba. *Bull. Chem. Soc. Japan* **14**, 478–82(1939)(in German); cf. Ehrenstein and Bunge, *C. A.* **29**, 471⁸; Treibs and Dinelli, *C. A.* **29**, 4356⁶.—The dehydrogenating action of Se on *trans-decahydro-6-methylquinoline* (I) and *octahydro-α-methylindole* (II) and the behavior of *quinoline* (III), *6-methylquinoline* (IV), *α-methylindole* (V) and *indole* (VI) on heating with Se are studied. I (4 g.) heated with 6 g. Se 27 hrs. at 160–290° gives IV and *tetrahydro-6-methylquinoline* (VII). The mixt. is sepd. by forming the chloroaurates and sorting out the dissimilar crystals. IV.$HAuCl_4$, light yellow needles, m. 181–2°; VII.$HAuCl_4$, deep yellow prisms, m. 134–5°. II.HBr (3.6 g.) heated with 6 g. Se 15 hrs. at 310–35° gives V, 0.46 g. propylbenzene and NH_3. The dehydrogenation products in the foregoing processes are obtained in a rather small yield III, IV and V when heated with Se at 310–20° remain unchanged to 80–90% whereas VI, treated in the same manner, may be recovered only in small amt. while H_2Se is developed. In addn. crystals, m. 192–5°, are formed. Dora Stern

The structure of rottlerin. III. K. S. Narang, J. N. Ray and B. S. Roy. *Proc. Natl. Inst. Sci. India* **5**, 249–51(1939); cf. *C. A.* **32**, 4983⁸; **33**, 601².—The previously proposed structure for tetrahydrorottlerone (I) is withdrawn and it is suggested that I is 2,2-dimethyl-3-(β-phenylpropionyl)-5,7-dihydroxybenzopyran. E. W. Scott



Amination in the heterocyclic series by sodium amide. R. Norris Shreve, E. H. Riechers, Harry Rubenkoenig and A. H. Goodman. *Ind. Eng. Chem.* **32**, 173–8(1940).—$NaNH_2$ is prepd. from Na and NH_3 in a ball-mill reactor and ground by steel balls, maintaining the NH_3 atm. Control is by the rate of H evolution. A purity over 95% is obtained. Addn. of C_5H_5N in theoretical amt. to the reactor cooled to 110° gives *2-NaHNC$_5$H$_4$N*. Such addn. is slow with the mill rotating. The temp. is gradually raised to 120° during the addn. and subsequently to 130°. When evolution of H ceases 2 hrs. later the mill is let cool to 75° and hot H_2O added to hydrolyze to 2-$H_2NC_5H_4N$ (I) and NaOH. On filtration and cooling I seps. as an oil and is vacuum-distd. A 2nd NH_2 group is introduced with more difficulty. In this case addn. of the theoretical amt. of C_5H_5N to the reactor cooled to 170° was started and that temp. was maintained. Heat is removed by air reflux of C_5H_5N. About 2–4 hrs. are required for addn. of C_5H_5N and 6–8 hrs. total. On cooling to 90° hot H_2O is added, the product filtered and 2,6-$(NH_2)_2C_5H_3N$ crystd. from the mother liquor contg. 12–15% of NaOH. It is recrystd. from C_6H_6. The yields never exceeded 55%. The use of white mineral oil as diluent showed no advantage. The best yields were with 2–5% of H_2O in the pyridine. Addn. of NaOH did not improve the yield. Optimum yields were obtained with this equipment at 160–170°. Lowering the amt. of C_5H_5N from theory showed no advantage, increasing it gave more monoamine. Addn. of NH_4Cl with the H_2O to decomp. the NaOH offered no advantage. Addn. of C_9H_7N to 2 moles of $NaNH_2$ suspended in boiling xylene was carried out in other equipment. Reaction took about 1 hr. and was followed by decompn. with H_2O and pptn. of diquinolyl and diquinoline from the xylene layer by concd. HCl. The aq. layer made alk. with NaOH was extd. with Et_2O and the xylene and ether exts. vacuum-distd. The *2-aminoquinoline* was recrystd. from PhMe. Foster Dee Snell

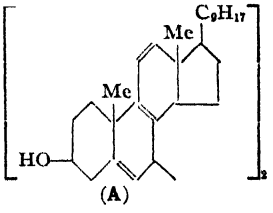
Sulfonation of 5,6-benzoquinoline. Jaroslaw Böhm. *Roczniki Chem.* **19**, 109–15(1939); cf. *C. A.* **33**, 3796⁸.—5,6-Benzoquinoline and 20% oleum at 100° (2 hrs.) yield 5,6-benzoquinoline-3′- and -5′-sulfonic acid, together with small amts. of a 3rd, unidentified acid, decompg. 369–78°. The products were identified by conversion into the corresponding phenols. 3′-Amino- and 3′-hydroxy-5,6-benzoquinoline m. 175.5–6.5° (literature 158°) and 245–7° (literature 208–11°), resp. B. C. P. A.

Constitution of matrine. XXVI. Genalkaloids of matrine and *d*-lupanine. Eiji Ochiai, Y. Ito and Masatake Maruyama. *J. Pharm. Soc. Japan* **59**, 705–10 (in German, 270–3)(1939).—*d*-Lupanine (I) when treated with 3% H_2O_2 gave *d-lupanine mono-N-oxide*, $C_{15}H_{24}N_2O_2$, which forms the following derivs.: *picrate*, decompg. 189°; *perchlorate*, decompg. 247°; *Au salt*, decompg. 216°; and *methiodide*, decompg. 137°. I (1.2 g.) in 5 cc. 9% HCl when treated with freshly prepd. CaO_2 for 30 min. gave *trilupine*, $C_{15}H_{24}N_2O_3$ (*d*-lupanine di-*N*-oxide), m. 127°. In like manner both matrine or hydroxymatrine when treated with CaO_2 gave the original compds. quantitatively. Sulfonation of I gave *thiolupanine*, $C_{15}H_{24}N_2S$, m. 102°; *thiolupanine picrate*, decompg. 225°. Sulfonation of matrine gave the original compd. quantitatively. *N*-Isoamylpiperidine and 2-methylindolizine when treated with H_2O_2 gave *N*-isoamylpiperidine oxide, m. 135° (picrate, m. 117°), and 2-methylindolizine oxide, an oil (picrate, m. 165°), resp., while *N*-isoamyl-α-piperidone gave the original compd. The structure of matrine is discussed on the basis of the above information. F. I. N.

Constitution of abietic acid. Di- and tetrahydroxy-

and chlorotrihydroxyabietic acids, and their oxidation products. Leon Sternbach. *Roczniki Chem.* **19**, 167–86(1939).—Abietic acid is oxidized ($KMnO_4$ in KOH) to dihydroxyabietic acid (I) (*Me ester*, m. 106–7°) and its oxide (II), together with an isomer (III), m. 130–50°, of tetrahydroxyabietic acid. III and HCl in $COMe_2$ give chlorotrihydroxy- (IV) and normal tetrahydroxyabietic acid. IV treated with *N* NaOH at 40° yields II, together with *tetrahydroxyabietolactone*, not melting at 330°, $[\alpha]_D$ −75.8° ± 1.5° in $CHCl_3$. II or III in aq. $COMe_2$ at room temp. undergo gradual conversion into *β-tetrahydroxyabietic acid*, softening at 130°, m. 151°, $[\alpha]_D$ − 67.7° ± 0.4° in MeOH. IV is oxidized by CrO_3 in AcOH to a *product*, $C_{20}H_{31}O_4Cl$, m. 154–6° (*semicarbazone*, m. 204–6°). I is oxidized by $Pb(OAc)_4$ to a *keto dicarboxylic acid* (V), $C_{20}H_{30}O_6$, m. 212–2.5°, while an isomeric *acid* (VI), m. 132–4°, is obtained similarly from II. II is probably IIa or IIb, V is Va or Vb, and VI is VIa or VIb.

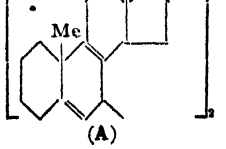
B. C. P. A.



The splitting of digitonides. Werner Bergmann. *J. Biol. Chem.* **132**, 471–2(1940).—The steroids and digitonin from digitonides can be more readily recovered by a simple modification of Schoenheimer's method (*C. A.* **27**, 1898) in which the C_5H_5N is removed by vacuum distn., thus avoiding the filtration of considerable vols. of Et_2O-C_5H_5N mixt. contg. suspended digitonin. Yields of recovered steroid as high as 95–8% may be obtained. A. P. Lothrop

Criteria for purity of chlorophyll preparations. G. Mackinney. *J. Biol. Chem.* **132**, 91–109(1940).—Because the prepn. of chlorophyll has been fraught with much uncertainty in the past, a method of prepn. is described which, although no new principle is involved, is so simplified as to largely remove these uncertainties. When the highly sensitive spectroscopic method of analysis is used, purity is assured only when the pigment is homogeneous and forms an entirely sep. zone on the Tswett column. The means to this end depend on the selection and standardization of the adsorbent. A. P. Lothrop

Some tetramethylammonium nucleates. Sergio Berlingozzi and Italo Bruzzesi. *Ann. chim. farm.* (Suppl. to *Farm. ital.*) Dec. **1939**, 15–20.—Yeast nucleic acid forms stable salts with 2 and with 4 mols. of Me_4NOH. The aq. solns. can be sterilized by boiling, without decompn.



L. E. Gilson

The constitution of dehydroergopinacol. Tosio Ando. *Bull. Chem. Soc. Japan* **14**, 482–6(1939)(in English); cf. *C. A.* **33**, 8502⁶.—*Ergopinacol* (I) *diacetate* is not dehydrogenated when treated with $Hg(OAc)_2$, thus differing from ergosterol (II) which forms under these conditions dehydroergosterol (III) (cf. Windaus and Linsert, *C. A.* **22**, 4534). This indicates that the double bonds conjugated in II are no longer in conjugation in I. That is consistent with Inhoffen's tentative formula for I (cf. *C. A.* **31**, 4984⁴). *Dehydroergopinacol* (IV) *diacetate* (V), obtained from IV with Ac_2O in pyridine or by exposing the acetate of III and eosin in EtOH to sunlight in the absence of air, forms needles from C_6H_6-EtOH, m. 195–6.5° (cor.), decomp. 200.5° (cor.), $[\alpha]_D^{23}$ −242° (11.9 mg. in 1 cc. $CHCl_3$). It shows an ultraviolet absorption max. at 275 mμ in 0.048% hexane soln. It gives a pink, light green and finally dark green color in the Rosenheim test. Whereas III (absorption max. at 320 mμ) contains 3 conjugated double bonds, the absorption max. 275 mμ of V indicates that only 2 of the double bonds of the latter are conjugated. A constitution (A) agreeing with this finding and with Inhoffen's formula for I is proposed for IV.

Dora Stern

The photochemical dehydrogenation of 7-dehydrocholestene. Akira Tominaga. *Bull. Chem. Soc. Japan* **14**, 486–9(1939)(in English).—In order to see whether or not the HO group in the 3-position of ergosterol takes part in the photochem. formation of the bimol. dehydrogenation product, the so-called ergopinacol (I), the behavior of *7-dehydrocholestene*, $C_{27}H_{44}$ (II), on irradiation is investigated. II is prepd. according to the method of Dimroth and Trautmann (*C. A.* **30**, 4506⁴). The specimens of II obtained under various conditions show an ultraviolet absorption spectrum which reveals that II is contaminated with isomeric cholestadiene which, however, is supposed to remain unaffected by the following irradiation. An alc.-C_6H_6 soln. of 300 mg. II and 300 mg. eosin, freed from air by a CO_2 stream and exposed to sunlight for a week, gives 40 mg. *"7-dehydrocholestenepinacone,"* $C_{54}H_{86}$ (III). The transition of II into III shows that the HO group in the 3-position is not necessary for the investigated photochem. dehydrogenation process, which is in favor with Inhoffen's formula for I (*C. A.* **31**, 4984⁴). A corresponding formula (A) is assigned to III. III m. 269–70° (cor., decompn.), $[\alpha]_D^{19}$ 260° (3.3 mg. in 1 cc. $CHCl_3$), and gives the color reactions of steroids.

Dora Stern

Sterols. XX. Homogeneity of bessisterol and properties of its double bonds. Satoru Kuwada and Sizuo Yosiki. *J. Pharm. Soc. Japan* **59**, 717–24(in German, 282–4)(1939); cf. *C. A.* **34**, 1026⁸.—Bessisterol (I) (0.5 g.) and 0.5 g. azobenzenecarbonyl chloride when heated on the oil bath at 170–80° gave bessisterol azoben-

zenecarboxylate, $C_{42}H_{56}N_2O_2$, m. 237.5–9.5°. I (1 g.) and 1 g. *m*-$(O_2N)_2C_6H_3COCl$ gave the *m*-dinitrobenzoate (II), $C_{56}H_{58}N_4O_6$, m. 199.5–204.5°, $[\alpha]_D^{25}$ 3.29°. Hydrolysis of II with alc. KOH gave I, $C_{28}H_{48}O.0.5H_2O$, m. 174–5°, $[\alpha]_D^{25}$ −13.5°; acetate, m. 185°, $[\alpha]_D^{25}$ −13.47°; benzoate, m. 202°, $[\alpha]_D^{25}$ 0°. Bessistenol (3 g.) in 25 cc. pyridine and 3 g. *m*-$(O_2N)_2C_6H_3COCl$ gave bessistenol *m*-dinitrobenzoate, $C_{56}H_{52}N_2O_8$, m. 206–9°, $[\alpha]_D^{25}$ 4.5°; bessistenol, $C_{28}H_{50}O$, m. 113–15.5°, $[\alpha]_D^{25}$ 17.53°; acetate, m. 115.5–17.5°. F. I. Nakamura

17-β-Hydroxyprogesterone. J. J. Pfiffner and H. B. North. *J. Biol. Chem.* **132**, 459–60(1940).—A new compd., 17-β-hydroxyprogesterone, which is an isomer of desoxycorticosterone, has been isolated in pure form during the prepn. of the various adrenal hormones from cattle glands. *17-β-Hydroxyprogesterone*, m. 212 15°, $[\alpha]_D^{25}$ 102°; *disemicarbazone*, darkens at 240°, sinters at 280–90°, blackens but does not m. below 360°; *dioxime*, sinters at 240°, m. 250–1° (decompn.). All m. ps. are uncor. It has no progestational activity and slight, if any, adrenal cortical activity. Its androgenic activity is of the same order as that of androsterone when tested in the castrated rat. A. P. Lothrop

Hydroxamic acids in qual. org. analysis (Davidson) **7**. Action of benzyl alc. on peptides and proteins (Overhoff) **11A**. Azo derivs. of sulfanilamide (Mossini) **25**.

Kipping, F. S., and Kipping, F. B.: Organic Chemistry. Revised ed. London: W. & R. Chambers, Ltd. 1029 pp. 9s.

Methyl Ethyl Ketone, Its Uses and Data on Its Properties. San Francisco: Shell Chemical Co. 58 pp.

Purifying chlorinated aliphatic hydrocarbons. John H. Reilly (to Dow Chemical Co.). U. S. 2,183,046, Dec. 12. A chlorinated satd. aliphatic hydrocarbon such as ethylene chloride contg. unsatd. impurities is treated with S chloride, and the chlorinated aliphatic hydrocarbon is distd. from the resulting mixt. in a relatively pure condition.

Catalytic dehydrogenation of hydrocarbons, as in forming propylene from propane. Herbert P. A. Groll and James Burgin (to Shell Development Co.). U. S. 2,182,431, Dec. 5. A process for the catalytic dehydrogenation of a hydrocarbon predominantly to an unsatd. hydrocarbon contg. fewer H atoms but the same number of C atoms to the mol. comprises bringing the substantially anhyd. vapors of a dehydrogenatable hydrocarbon contg. at least 2 C atoms into contact with a catalyst essentially consisting of an "activated alumina," prepd. by calcining, at a temp. of 300–800°, an Al hydroxide which was slowly pptd. from its aq. alk. soln. at a temp. of about 500–650°, whereby rupture of C-to-C bonds is substantially obviated and the treated hydrocarbon is predominantly dehydrogenated to an unsatd. hydrocarbon contg. the same number of C atoms.

Polymerizing olefins. Richard Michel (to I. G. Farbenind. A.-G.). U. S. 2,182,617, Dec. 5. Polymerization of a normally gaseous olefin contg. at least 3 C atoms such as C_3H_6 or iso-C_4H_8 is effected in the presence of a catalyst such as concd. H_3PO_4 and of an excess of a normally formed reaction product such as isononylene or triisobutylene to suppress further formation of the latter during the polymerization.

Interpolymerization of olefins such as isobutene and normal butene. Richard M. Deanesly and Aaron Wachter (to Shell Development Co.). U. S. 2,181,640, Nov. 28. A process for the interpolymerization of a tertiary olefin with a dissimilar olefin of a lower order of reactivity comprises heating the tertiary olefin with a substantial mol. excess of the dissimilar olefin in the presence of an acidic polymerization catalyst under a superatm. pressure and at a temp. of from 60–250° for a time sufficient to effect substantial interpolymerization with no substantial decompn. of the olefinic reactants and products.

Catalytic hydrogenation of ε-caprolactam to amines. Wilbur A. Lazier and Geo. W. Rigby (to E. I. du Pont de Nemours & Co.). U. S. 2,181,140, Nov. 28. By the catalytic hydrogenation of ε-caprolactam at a temp. of about 200–400°, amines such as hexamethylenediamine, etc., are produced. Several examples with details are given.

Amines. Rudolph L. Hasche (to Eastman Kodak Co.). U. S. 2,182,807, Dec. 12. See Brit. 501,763 (*C. A.* **33**, 6340[8]).

Forming ether derivatives of polyhydric alcohols. Eddy W. Eckey (to Procter & Gamble Co.). U. S. 2,182,397, Dec. 5. In forming an ether deriv. of a polyhydric alc., such as a stearic acid ester of a polyglycerol, a mixt. of an ester consisting of a polyhydric alc. partially esterified with a carboxylic acid, such as stearic acid, a "water carrier" such as toluene having a lower b. p. than such other materials and immiscible with water, and a catalyst which may be H_2SO_4 or a sulfonic acid, is subjected to boiling and the water thus formed is distd. off.

Hydroxyalkyl ethers of benzophenone. Gerald H. Coleman and Clarence L. Moyle (to Dow Chemical Co.). U. S. 2,182,786, Dec. 12. By reactions such as that of a hydroxybenzophenone of a nuclear halogenated deriv. with an alkylene chlorohydrin (suitably in a solvent such as aq. EtOH with heating to 55–65°), products are obtained such as the β-hydroxyethyl ether of 4-hydroxybenzophenone, m. about 83°, the β-hydroxyethyl ether of 3-chloro-4-hydroxybenzophenone, an amber oil, and other compds. such as β-hydroxyethyl ethers of 4'-chloro-4-hydroxybenzophenone, 3,4'-dichloro-4-hydroxybenzophenone, 3-bromo-4-hydroxybenzophenone, 2-hydroxy-3,5,6-trichlorobenzophenone, 2-hydroxybenzophenone, 2-hydroxy-3-chlorobenzophenone; hydroxybutyl ether of 2',4',6'-trichloro-4-hydroxybenzophenone, hydroxyamyl ether of 3,5-dibromo-4-hydroxybenzophenone, hydroxypropyl ether of 3-chloro-4'-bromo-4-hydroxybenzophenone, etc. Cf. *C. A.* **33**, 6877[7].

Terpene ethers. Donald H. Sheffield (to Hercules Powder Co.). U. S. 2,182,826, Dec. 12. See Brit. 494,504 (*C. A.* **33**, 2535[2]).

Cyclic acetals of formaldehyde. Kurt Billig (to I. G. Farbenind. A.-G.). U. S. 2,182,754, Dec. 5. An aq. soln. of CH_2O is treated with an α-alkylene oxide, such as ethylene oxide, for the production of glycol formaldehyde acetal, at a temp. of about 50–100° in the presence of a strongly acid condensation catalyst such as H_2SO_4 and the resulting intermediate condensation product is heated to about 100–150° in the presence of a catalyst which may be HCl, HBr or their acid-reacting metal salts.

Separating ketones of the sterol series. Fritz Hanusch (to C. F. Boehringer & Soehne G. m. b. H.). U. S. 2,183,072, Dec. 12. For the sepn. of androstenedione and progesterone from cholestenone, the mixt. is dissolved in a solvent such as benzene and the resulting soln. is extd. with a soln. of a metal salt (other than a salt of an alkali or alk. earth metal) such as a concd. soln. of $ZnBr_2$ or Sn chloride to dissolve the androstenedione and progesterone without dissolving the cholestenone. Several examples, with details, of similar treatment are given.

"Bis-phenols." Edgar C. Britton and Fred Bryner (to Dow Chemical Co.). U. S. 2,182,308, Dec. 5. A method of making a "bis-phenol" such as bis(4-hydroxyphenyl)dimethylmethane by treating a phenol such as PhOH with a ketone such as acetone in the presence of an inorg. acid such as HCl involves the steps of washing the reacted mixt. with water to remove most of the inorg. acid, neutralizing the residual inorg. acid (suitably with lime), and then distg. off the unreacted phenol for obtaining a purified product.

Derivatives of a phenol obtained from cashew-nutshell oil. Solomon Caplan (to Harvel Corp.). U. S. 2,181,119, Nov. 28. A new compd. called cardanol, of the probable formula $C_{14}H_{27}C_6H_4OH$, b_{10} 225°, is obtained by distg. cashew-nutshell liquid at a greatly reduced pressure or in a stream of steam at atm. pressure, and by catalytic hydrogenation yields a compd. of the probable formula

$C_6H_4OHC_{14}H_{29}$ (1,3), m. about 50.5° and b. about 380° (b_{10} 240°). Ethylation with Et_2SO_4 produces ethyl cardanol, b_{10} about 235°, and reaction with benzoyl chloride forms cardanyl benzoate, b_7 about 290°. With α-chloropropionic and chloroacetic acids, cardanol reacts to form cardanolpropionic acid, $C_{14}H_{27}C_6H_4OC_2H_4COOH$, and cardanolacetic acid, $C_{14}H_{27}C_6H_4OCH_2COOH$. Hydrogenated cardanol may be used as a plasticizer in cellulose acetate lacquers, etc., or for reaction with CH_2O in producing synthetic resins and its alkyl ethers may be used as high-boiling heat-transfer liquids. Ethers of cardanol and of hydrogenated cardanol may also be used as *plasticizers for lacquer materials* and as *fixatives for perfumes*. Cardanol benzoate has an odor similar to that of Russian leather and may be used *for odorizing* other *leathers* or *artificial leather*.

Catalytic hydrogenation of mononitrated phenols. Clyde O. Henke, Wm. A. Douglass and Roland G. Benner (to E. I. du Pont de Nemours & Co.). U. S. 2,183,019, Dec. 12. Catalytic hydrogenations such as that of *p*-nitrophenol to *p*-aminophenol in the liquid phase in the presence of a Ni catalyst are effected at temps. of about 50–175° under a pressure above 100 lb. per sq. in. and with the initial reactants adjusted to a pH of about 6.0–11.6.

Dinitro derivatives of saturated nonbenzenoid hydrocarbons. Henry B. Hass and Leon W. Seigle (to Purdue Research Foundation). U. S. 2,181,531, Nov. 28. For the production of a dinitro compd. such as 2,3-dimethyl-2,3-dinitrobutane, a salt of a secondary nitro deriv. of a satd. nonbenzenoid hydrocarbon such as the Na salt of 2-nitropropane is condensed with a secondary halo nitro deriv. of a satd. nonbenzenoid hydrocarbon having the halogen and the nitro group on the same C atom, such as 2-chloro-2-nitropropane (suitably by heating in abs. alc. for 7 hrs. at refluxing temp.).

Hydrogenating aromatic hydrocarbons, as in forming 1,4-dihydrobenzene from benzene or dihydrotoluene from toluene. Charles B. Wooster (to E. I. du Pont de Nemours & Co.). U. S. 2,182,242, Dec. 5. In a liquid solvent which may be liquid NH_3 or an aliphatic amine which dissolves alkali metal, reaction is effected between an aromatic org. compd. such as benzene or toluene, an alkali or alk. earth metal or Mg, and a hydrolytic agent such as MeOH which reacts with Na in liquid NH_3 soln. in the absence of a catalyst to evolve H but which will not react completely with NH_3 to form an NH_4 salt (suitably by heating with refluxing). Various examples are given.

Pyrolysis of *sec*-butylbenzene and its derivatives. Robert R. Dreisbach (to Dow Chemical Co.). U. S. 2,182,313, Dec. 5. Allylbenzene is produced by pyrolyzing vaporized *sec*-butylbenzene (suitably by brief heating with superheated steam at about 550°). Chloro-*sec*-butylbenzene, similarly pyrolyzed, yields chloroallylbenzene. A mixt. of isomeric ethyl-*sec*-butylbenzenes yields ethylallylbenzenes, ethylvinylbenzenes, styrene and some ethyl- and diethyl-benzenes. Similarly, *sec*-butyl-3,5-dichlorobenzene may be pyrolyzed to obtain allyl-3,5-dichlorobenzene, *sec*-butyl-3-bromo-benzene may be pyrolyzed to obtain allyl-3-bromobenzene, *sec*-butyl-3-chloro-5-methylbenzene may be pyrolyzed to obtain allyl-3-chloro-5-methyloenzene, etc. In pyrolyzing such *sec*-butylbenzene compds. numerous by-products are frequently obtained. These by-products usually include styrene homologs and analogs useful in prepg. synthetic resins.

Hydrolysis of 1,3-dihalobutanes. Edgar C. Britton and Gerald H. Coleman (to Dow Chemical Co.). U. S. 2,181,297, Nov. 28. In prepg. a product such as 1-chloro-3-hydroxyisobutane, a 1,3-dihaloisobutane such as 1,3-dichloroisobutane is treated with an aq. alk. agent such as NaOH at a temp. between 75° and 200° (suitably 175° for 23 hrs.). Several examples are given.

Chlorinating nitromethane. Byron M. Vanderbilt (to Commercial Solvents Corp.). U. S. 2,181,411, Nov. 28. For the production of chloropicrin an aq. soln. of nitromethane is treated with a chlorinating medium contg. Cl and an alkali or alk. earth metal hypochlorite with the Cl present in sufficient amt. to convert all the metal hydroxide formed into the corresponding hypochlorite.

Benzenecarboxylic acid fluorides containing trifluoromethyl groups. Herbert Kracker, Otto Scherer, Fritz Müller and Willy Schumacher (to General Aniline Works). U. S. 2,181,554, Nov. 28. Benzoyl fluorides contg. trifluoromethyl groups (and which may be used as intermediates in making dyes and pharmaceutical compds.) are produced by the reaction of HF or SbF_3 by heating with benzoyl chlorides substituted by one or more trichloromethyl groups. Products thus obtainable include: trifluoromethylbenzoyl fluoride, b. 158–62°; 4-trifluoromethyl-3-chlorobenzoyl fluoride, *m*-trifluoromethylbenzoyl fluoride, b. 159–63°; 3,5-bis(trifluoromethyl)benzoyl fluoride, b. 158–62°; 5-trifluoromethyl-1,3-benzenedicarbonyl fluoride, b_{15} 88°; 4-trifluoromethyl-1,2-benzenedicarbonyl fluoride, and various related compds., details of the production of some of which are given.

Triaryl phosphates. Clarence L. Moyle (to Dow Chemical Co.). U. S. 2,182,817, Dec. 12. Products are formed which do not cause blushing of cellulose ether compns. when used in them as plasticizing agents, and which have the general formula $[(4\text{-}Me_3C\text{-}2\text{-}MeC_6H_3O)_n\text{-}(RO)_{n'}]P{:}O$, where R represents an aryl radical and n and n' each represents an integer, the sum of n and n' being equal to 3, as by treating a P oxyhalide with *p-tert*-butyl-*o*-cresol and if required with another phenol such as PhOH, cresol, naphthol, *p*-cyclohexylphenol, 2,4-dimethylphenol, etc., and an alkali metal salt of a phenol. Details are given of the production of: tris(*p-tert*-butyl-*o*-tolyl) phosphate, b_8 304–8°; bis(*p-tert*-butylphenyl) *p-tert*-butyl-*o*-tolyl phosphate, b_8 314–18°; and di-*p*-xenyl *p-tert*-butyl-*o*-tolyl phosphate, b_8 178–385°, and mention is also made of the production of other products such as *p-tert*-butyl-*o*-tolyl dinaphthyl phosphate, bis(*p-tert*-butyl-*o*-tolyl) 2,4-dichlorophenyl phosphate, *p-tert*-butyl-*o*-tolyl bis(2-methyl-5-isopropylphenyl) phosphate, *p-tert*-butyl-*o*-tolyl bis(*p*-cyclohexylphenyl) phosphate, bis(*p-tert*-butyl-*o*-tolyl) *p-tert*-octylphenyl phosphate, *p-tert*-butyl-*o*-tolyl bis(2,4,6-triethylphenyl) phosphate, etc.

Mixed triaryl phosphates. Edgar C. Britton and Clarence L. Moyle (to Dow Chemical Co.). U. S. 2,182,309, Dec. 5. Mixed triaryl phosphates contg. a single 2,4-dibromophenyl group and which may be used as plasticizers with cellulose esters or ethers or a core fluid for golf balls may be prepd. by treating a P oxyhalide with 2,4-dibromophenol to form 2,4-dibromophenyl-phosphoric acid dihalide and then treating this intermediate with a phenol such as PhOH, cresol, naphthol, *p*-phenylphenol or the like to form the mixed triaryl phosphate product. Details are given of the production of 2,4-dibromophenyl diphenyl phosphate, b_5 273–83°, and having a sp. gr. of 1.627, 2,4-dibromophenyl dicarvacryl phosphate, b_8 295–305°, and having a sp. gr. of 1.4, 2,4-dibromophenyl phenyl *o*-tolyl phosphate, b_8 270–85°, and having a sp. gr. of 1.56, and 2,4-dibromophenyl di-*o*-tolyl phosphate, b_8 290–300°, and having a sp. gr. of about 1.58; and general mention is made that the 2,4-dibromophenyl phosphoric acid dihalide may be treated with *p*-ethylphenol to form 2,4-dibromophenyl bis(*p*-ethylphenyl) phosphate; with *o*-chlorophenol to form 2,4-dibromophenyl bis(*o*-chlorophenyl) phosphate; with *p-tert*-butylphenol and *p*-phenylphenol to form 2,4-dibromophenyl *p-tert*-butylphenyl *p*-xenyl phosphate; with 2,4-dimethylphenol to form 2,4-dibromophenyl bis(2,4-dimethylphenyl) phosphate; with α-naphthol to form 2,4-dibromophenyl di-α-naphthyl phosphate; with isopropylphenol and *m*-cresol to form 2,4-dibromophenyl isopropylphenyl *m*-tolyl phosphate; with 2,4,6-triethylphenol to form 2,4-dibromophenyl bis(2,4,6-triethylphenyl) phosphate; with thymol and phenol to form 2,4-dibromophenyl thymyl phenyl phosphate; with *o*-cyclohexylphenol to form 2,4-dibromophenyl bis(*o*-cyclohexylphenyl) phosphate; etc.

Alkylated phenols. Donald R. Stevens and Joseph E. Nickels (to Gulf Research & Development Co.). U. S. 2,181,823, Nov. 28. A monohydroxy phenolic compd.

alkylated in the hydroxylated nucleus, such as 2,6-di-*tert*-butyl-4-phenylphenol, is produced by heating a mixt. of an olefin such as isobutylene and a monohydroxy phenolic compd. such as *p*-hydroxybiphenyl in the presence of a soln. of an alkali metal sulfate or NH_4 sulfate in H_2SO_4.

Alkylation of naphthenes. Aristid V. Grosse (to Universal Oil Products Co.). U. S. 2,182,557, Dec. 5. A process for the production of alkyl derivs. of naphthene hydrocarbons having at least 6 C atoms in the ring, such as methylcyclohexane involves treating the naphthene hydrocarbon with a cycloparaffin having less than 5 C atoms in the ring, such as cyclopropane, in the presence of a metal halide such as $AlCl_3$ and a H halide such as HCl (suitably at a temp. of −10°).

Sebacic acid. Herman A. Bruson and Lloyd W. Covert (to Röhm & Haas Co.). U. S. 2,182,056, Dec. 5. Sebacic acid is produced by a process which involves heating a functional deriv. of ricinoleic acid such as castor oil with an alkali metal hydroxide or carbonate in aq. soln. to above 175° and under superatm. pressure at least equal to the vapor pressure of the reaction mixt. at the temp. used.

Reactions such as the production of acetaldehyde and vinyl chloride from ethylene chloride. James L. Amos (to Dow Chemical Co.). U. S. 2,183,036, Dec. 12. For converting a 1,2-olefin dihalide substantially only to the corresponding aldehyde and monohalo-olefin, one part of the dihalide is mixed with about 1.3–8.1 parts of steam superheated to give the resultant mixt. a temp. of about 300–800° and it is passed over a surface catalyst such as activated alumina at such a temp.

Hydroxypropanone. Raymond W. McNamee and Charles M. Blair (to Carbide and Carbon Chemicals Ltd.). Can. 386,591, Jan. 30, 1940. Hydroxypropanone is prepd. by dehydrogenating 1,2-propylene glycol vapor at about 265° in the presence of a reduced Cu and Cr catalyst.

Stabilizing vinyl acetate. Gelu S. Stamatoff (to E. I. du Pont de Nemours & Co.). U. S. 2,182,528, Dec. 5. Polymerization of monomeric vinyl acetate is inhibited by the addn. of about 0.2% or less of rosin or a resinate of Cu, Zn, Mg, Al or Co.

Diisobutylene. Wallace A. McMillan (to The Texas Co.). U. S. 2,181,642, Nov. 28. An arrangement of app. is described, and a process for the manuf. of diisobutylene from an unsatd. C_4 hydrocarbon fraction contg. isobutylene, which comprises selectively converting the isobutylene into *tert*-butyl chloride by bringing the hydrocarbons in the liquid phase into contact with dry HCl, sepg. the *tert*-butyl chloride by fractionation, decompg. the isobutyl chloride to isobutylene and HCl, under the influence of heat, subjecting the resulting mixt. while hot and at a slightly reduced temp. to polymerization in the presence of a catalyst immune to HCl poisoning, whereby the isobutylene is polymerized to diisobutylene, sepg. the diisobutylene from the HCl and recycling the HCl for conversion of addnl. isobutylene to *tert*-butyl chloride.

***β*-Lactose.** Paul F. Sharp and David B. Hand (to Cornell Research Foundation). U. S. 2,182,618, Dec. 5. App. is described, and a process of producing *β*-lactose which consists in heating any other form of lactose while in a pulverulent condition in an atm. of water vapor at a temp. maintained above the transition point and vapor pressure sufficiently high to cause the formation of a temporary soln. on the surface of the lactose particles, while limiting the amt. of moisture so that the particles remain in a pulverulent condition, continuing the process until the lactose is converted into the beta form, and then permitting the surplus moisture to escape, leaving dry cryst. *β*-lactose. U. S. 2,182,619 relates to a process of producing *β*-lactose crystals which involves heating *α*-lactose hydrate crystals at a sufficiently high temp. to drive off the water of crystn., maintaining some of the water of crystn. so driven off in a moisture-confining zone (of a described app.) in intimate assocn. with the crystals and maintaining the temp. above the transition point until the crystals are substantially transformed into *β*-lactose crystals, and then allowing the water to escape, so that dry *β*-lactose crystals remain.

Methyl violet purification. Orville S. Frank (to Sherwin-Williams Co.). U. S. 2,181,369, Nov. 28. A process for deodorizing methyl violet comprises subjecting an aq. soln. of a water-sol. methyl violet salt to the extg. action of a solvent liquid which forms a separable layer with the soln. and which is incapable of dissolving all of the methyl violet from the aq. soln., whereby the liquid takes up objectionable malodorous bodies from the aq. soln., and sepg. the resulting 2 liquid phases.

Azeotropic distillation and concentration of acetic and propionic acids. Jack J. Gordon and Arthur W. Bright (to Eastman Kodak Co.). U. S. 2,171,549, Sept. 5. An arrangement of app. is described, and a process, which as applied to the concn. of aq. HOAc may be continuous and may comprise vaporizing and feeding the aq. HOAc, fractionating water and HOAc from the HOAc, bringing this fractionated acid and water into contact with a small quantity of PrOAc and PrOH entrainer in a zone near but above the feed, removing the resultant vapors from the contact zone, bringing these vapors into contact in a second zone with further and larger quantities of PrOAc and PrOH entrainer, fractionating and vaporizing a ternary azeotrope PrOAc, PrOH and water vapors from the second zone, condensing and sepg. these vapors to obtain PrOAc and PrOH entrainer and employing this sepd. entrainer for the aforementioned smaller and larger PrOAc and PrOH entrainer additions by returning the sepd. entrainer to the two zones mentioned. U. S. 2,171,550 (Jack J. Gordon, sole inventor; to same assignee) involves a method for controlling the entrainer content of a balanced azeotropic distn. system, employing a multicomponent entrainer comprising a major portion of aliphatic ester and a minor portion of aliphatic alc. greater than 3% for dehydrating aq. solns. contg. at least one lower aliphatic acid, which comprises gradually adding to the system from time to time during a 24-hr. period, small amounts of the aliphatic alc., for control and replenishment. In concg. HOAc, a major proportion of PrOAc and a minor proportion of PrOH may be used, as may also BuOAc and BuOH or AmOAc and AmOH.

Salts of diarylaminoalkylcarbinols. Chemische Werke Albert (Emil Eidebenz and Hans Mengele, inventors). Ger. 675,817, May 17, 1939 (Cl. 12*q*. 32.21). Salts readily sol. in water are prepd. by converting diarylaminoalkylcarbinols into salts of mono- or polyhydroxy monocarboxylic acids. The carbinols and acids may be fused together in the presence of a little water to produce the salts. Thus, (dimethylaminomethyl)di-2,5-xylylcarbinol is fused with lactic acid to give a sol. lactate. Other examples are given.

The growth of populations of Protista and the allelocatalytic effect. Wilhelm Ludwig and Charlotte Boost. *Arch. Protistenk.* 92, 453–84(1939); cf. L., *Biol. Generalis* 4, 351–76(1928).—From an analysis of the population curves (sp. growth velocity plotted against increase in population) it follows that populations of *Protista* in media, which have not been changed, behave as if, firstly, the initial amt. of nutrient is gradually consumed and, secondly, the conditions for increase become more and more favorable through accumulation of the auto-excretion products in the surrounding medium, until the optimal

concn. is exceeded. Allelocatalytic effects in *Protista* are widely distributed. In most cases, at least, the allelocatalytic effect presumably depends upon an action of the auto-excretion products which favors the population increase, perhaps through a change in the pH or the oxidation-reduction potential of the medium. The biol. basis for this is seen in the fact that most *Protista* in nature live in dense populations, so that the optimal concn. of auto-excretion products is not small. Ruth Berggren

Organisms in time. Theodore W. Torrey. *Quart. Rev. Biol.* **14**, 275–88(1939).—A review, including a section on comparative biochemistry. J. B. Brown

Alkali fibrinate and caseinate as catalases. Martin H. Fischer and Werner J. Suer. *Kolloid-Z.* **89**, 13–20 (1939).—See *C. A.* **33**, 6886[2]. S. A. Corson

Use of isolated radiation in experiments with the rat. II. Effects of darkness and of visible and infrared radiation on three successive generations of rats. (*a*). **Growth and storage of vitamin A.** Ethel M. Luce-Clausen and Elizabeth F. Brown. *J. Nutrition* **18**, 537–49(1939); cf. *C. A.* **23**, 4498; **24**, 1889.—Radiation in the visible region of the spectrum promotes growth in rats fed the Sherman B diet as compared with rats fed the same diet but kept in darkness. This effect is more pronounced in the third generation, and is more marked in males than in females. Radiations in the near and far infrared regions have a growth-promoting effect which is lesser in degree than that of visible light. Rats kept in darkness and fed the Sherman B diet, and also groups fed a diet contaminated with F store more vitamin A in livers at a more rapid rate for wt. at given ages than do comparable groups exposed for 12 hrs. a day to visible light. Lack of retinal stimulation by light may play a part in this result. III. (*b*) **Reproduction.** *Ibid.* 551–62.—Age of onset of 1st estrus and also of opening of the vagina are delayed in rats kept in darkness. Radiations in the visible region of the spectrum speed up these physiol. functions in rats. Radiation plays a definite part in promoting the normal survival of young born in succeeding generations reared under controlled conditions of light. The most effective radiations are in the visible, but near and far infrared radiations are also of some value. Radiation plays a part in rat reproduction. In the near and far infrared equal results were demonstrated, with equal energy equivs. in these 2 regions. By using in the visible region $^1/_3$ the energy of that used in the infrared, the best results were obtained. C. R. Fellers

Tyrosinase in feather germs. Donald R. Charles and Mary E. Rawles. *Proc. Soc. Exptl. Biol. Med.* **43**, 55–8 (1940).—Exts. of black chicken feather germs show a cyanide-sensitive, heat-labile tyrosinase activity, forming melanin from tyrosine without added peroxide, in about 80% of trials when 1 cc. of the reaction mixt. contains ext. of 50–750 mg. of young barb tissue. Exts. of red feathers show a similar activity in about 60% of cases, forming black rather than red pigment. Exts. of White Leghorn germs do not contain tyrosinase and do not inhibit the tyrosinase of black feather germs. L. E. Gilson

Histological demonstration of vitamin A in rats by means of fluorescence microscopy. Hans Popper. *Proc. Soc. Exptl. Biol. Med.* **43**, 133–6(1940).—Vitamin A shows a green fluorescence in ultraviolet light which disappears rapidly during the irradiation. Fluorescent green droplets can be seen in tissue sections, especially in the Kupffer cells of the liver, if the animal has not been deprived of vitamin A. L. E. Gilson

Changes of cholinesterase at end plates of voluntary muscle following section of sciatic nerve. R. Couteaux and D. Nachmansohn. *Proc. Soc. Exptl. Biol. Med.* **43**, 177–81(1940).—The main bulk of the enzyme at the end plates is located outside the nerve endings. With their removal only a small amt. disappears. Later the enzyme concn. decreases but still remains high. Regeneration of the muscle fibers leads to an increase in both concn. and total amt. of cholinesterase. L. E. Gilson

Relation of calcium proteinate and colloidal tricalcium phosphate to the partition of calcium in the blood stream. David M. Greenberg and Clarence E. Larson. *J. Phys. Chem.* **43**, 1139–50(1939).—The partition of the Ca and inorg. phosphate is detd. by ultrafiltration of the blood serum through collodion membranes. Ca is varied by injection of Ca salts, of parathyroid hormone and of large doses of vitamin D. Variation in the serum protein is produced by plasmapheresis. Evidence is presented for the formation of a colloidal $Ca_3(PO_4)_2$ in serum. A linear equation based on the law of mass action governing the relations between Ca and total serum protein is derived. The dissocn. const. of the Ca proteinate and the max. Ca-combining power of the protein of the serum are evaluated. Plasmapheresis expts. are used to obtain data from which the Ca-combining power of albumin and globulin is derived for normal blood Ca levels. L. Kolodny

Seasonal variations in the chemical composition of vertebrate tissues. V. V. Koval'skiĭ. *Biochem. J.* (Ukraine) **12**(in Russian, 355–61; in English, 362–8) (1938).—An outline of the biol. importance of the problem of seasonal variations in the animal organism is followed by a review of research in this field from 1916 to the present time. A. H. Krappe

The reaction between iodoacetic acid and denatured egg albumin. Lawrence Rosner. *J. Biol. Chem.* **132**, 657–62(1940).—The denatured egg albumin used in the work was not permitted to coagulate by adjusting the reaction to pH 7.3 and placing the mixt. for 10 min. in H_2O which had been brought to a boil. Iodoacetic acid reacts much more rapidly with such a soln. than with a coagulum. There is an initial rapid production of iodide lasting no longer than 10 min., and then the reaction slackens and after 40 min. proceeds at a steady, much slower pace. The initial sharp rise in iodide is undoubtedly mainly a result of the interaction between the iodoacetate and the —SH groups of the protein. The slower steady yield is due to some other group or groups as yet unidentified. Extrapolation of this non-sulfhydryl iodide to zero time yields a value for available cysteine of 0.55% in heat-denatured and 0.87% in urea-denatured egg albumin. With solns. of native albumin no iodide was found at the end of 5 hrs. in the presence of iodoacetate. The —SH groups in a soln. of denatured albumin are quite labile, their disappearance probably indicating their oxidation. On the other hand, the non-sulfhydryl groups are apparently not susceptible to destruction, since their rate of iodide production is not diminished after standing. A. P. Lothrop

An esterase from muscular tissue. M. B. Matlack and I. W. Tucker. *J. Biol. Chem.* **132**, 663–7(1940).—An enzyme is present in beef and other muscular tissues which has the characteristics of an esterase and shows marked activity at temps. below 0°. The enzyme is so firmly attached to the muscle protein that even autolysis does not liberate it and it appears, therefore, to be a true muscle enzyme. It can be prepd. from well-washed tissue by the use of dil. alkali, digitonin, digitalin or saponin. It shows its best activity at pH 6 in the presence of phosphate and is considerably inhibited by bile. A. P. L.

Phosphatase studies: the hydrolysis of aminoethyl phosphate and β-glycerophosphate by fecal and kidney phosphatase. Russell V. Bowers, Edgar L. Outhouse and J. C. Forbes. *J. Biol. Chem.* **132**, 675–80(1940); cf. *C. A.* **30**, 3510[7].—The optimum pH for fecal and kidney phosphatases acting on both Na aminoethylphosphate (I) and β-glycerophosphate (II) are 8.8 and 9.2, resp. The optimum Mg concns. for the activation of fecal phosphatase are different for the 2 substrates, being 0.08 to 0.1 *M* for I and 0.005 *M* for II. Kidney phosphatase on the other hand requires 0.005 *M* for both. This is a hitherto unknown characteristic of fecal phosphatase and, since there is no apparent difference in the Mg requirement when kidney phosphatase is used, it definitely indicates a fundamental difference between the 2 enzymes. The results suggest that the use of aminoethyl phosphate as substrate might be of value in distinguishing between phosphatases from different sources. The rate of hydrolysis of I by both enzymes is only approx. $^2/_3$ that of II. A. P. Lothrop

The ultraviolet absorption spectrum of prolactin.

Abraham White and G. I. Lavin. *J. Biol. Chem.* **132**, 717-21(1940); cf. *C. A.* **31**, 7075⁷.—The ultraviolet absorption spectrum of cryst. prolactin has a band with the max. absorption at about 2800 A. Narrow bands appear in photographs taken with the continuous light source of the H discharge tube and suggest the presence of tryptophan, tyrosine and phenylalanine. A. P. L.

Stimulation of growth in Aspergillus niger under exposure to low-velocity cathode rays. C. E. Buchwald and R. M. Whelden. *Am. J. Botany* **26**, 778-84(1939).—Growth of *Aspergillus niger* was stimulated by irradiation with cathode rays of 1.5-3.0 kv. No explanation of the effect is known. Nelson McKaig, Jr.

The action of benzyl alcohol on peptides and proteins. J. Overhoff. *Atti X° congr. intern. chim.* **3**, 263-7(1939) (in German).—In attempting to degrade proteins by means of org. reagents it was found that gelatin and casein dissolve easily in benzyl alc. when heated to 200°. Under these conditions glycine, alanine, glycine anhydride, and aspartic acid remain unchanged. Glutamic acid forms an oil; benzoylglycylglycine is converted to the *benzyl ester*, m. 125°, and the benzyl ester of hippuric acid, m. 91°. The latter can be formed directly from the constituents. Com. gelatin was heated 1 hr. at 210° with 3 parts benzyl alc., filtered, and most of the product was pptd. by ether. The benzyl ester of proline remained in soln. and was recovered by evapn. During the reaction 2% of the total N was evolved as NH_3. No free amino groups were formed, but the ether-insol. product contained one benzyl group for each 7 N atoms. It was partly sol. in H_2O or alc. and sol. in 50% alc. It contained 13.9% N and gave a pos. biuret reaction. The benzyl groups were removed by acid hydrolysis, leaving a weakly acid substance which became strongly acid on benzoylation. R. E. Reeves

Properties of the steady state compared to those of equilibrium as shown in characteristic biological behavior. Alan C. Burton. *J. Cellular Comp. Physiol.* **14**, 327-49 (1939).—The steady state is the common basis of constitution of biol. systems which explains many of the common characteristics of their behavior. Felix Saunders

Ion exchanges in accumulation and loss of certain ions by the living protoplasm of Nitella. S. C. Brooks. *J. Cellular Comp. Physiol.* **14**, 383-401(1939); cf. *C. A.* **33**, 8645².—Three processes occur during the absorption of the ions. (*a*) Induced accumulation takes place rapidly, even in 1 min., but may possibly continue 1-3 hrs. The measured amts. of absorbed ions greatly exceed the amt. susceptible to combination with the plasma membrane and correspond approx. with the salt-combining groups of the constituents present in *Nitella* protoplasm. (*b*) Primary accumulation appears noticeably after 1-3 hrs. of immersion of *Nitella* in these salt solns. This process is intermittent, reaching several successive max. which greatly exceed the permissible amts. of ions calcd. to be combined with the protoplasmic constituents. These ions seem to be accumulated by exchange for metabolic products (org. ions). These org. ions may include many so-called waste products. Alternating with these periods of absorption occur periods during which the radioactive ions are lost from the cells. This loss is due in part to the displacement of these ions from combination with the protoplasm, as well as to replacement of these ions from the protoplasmic matrix. The first of these loss phases is conspicuous. All of these processes can be formulated as ion exchanges and are believed to take place between the water phase and the condensed phases of proteins, fats, etc. In these condensed phases ions move from 1 reactive group to another, exchanging positions with the previously present ions at the other groups. By this means ions pass rapidly through the plasma membrane, provided that easily movable ions are present for exchange. The permeabilities involving 2 univalent inorg. ions are of the order of 10^{-7} g. mols. cm.$^{-2}$ hr.$^{-1}$, a rate closely comparable with those observed for water and for small nonelectrolyte mols. Felix Saunders

Effect of radiation from radioactive indicators on the penetration of ions into Nitella. Lorin J. Mullins. *J. Cellular Comp. Physiol.* **14**, 403-5(1939).—Radiation from radioactive Na decreased the amt. of penetration of ions where the concn. of radioactive ion is greater than 1.0 mc. per l. This decrease in the case of induced accumulation is presumably due to a decrease in the no. of exchange positions in the protoplasm. If any "isotope effect" exists it must be masked by the radiation effects of these radioactive indicators. Felix Saunders

The bilichrysins. A new type of bile pigment. Rudolf Lemberg and Wm. Hutton Lockwood. *J. Proc. Roy. Soc. N. S. Wales* **72**, 69-74(1939).—Two new types of bile pigment, differing from all other known types, and yellow in color, have been prepd. from biliverdin (I) and mesobiliverdin (II) by oxidation with alc. I soln. *Mesobilichrysin* (III) is obtained by adding 10.24 ml. 0.1 *N* alc. I soln. slowly, with shaking, to a soln. of 300 mg. II and 200 mg. $Zn(OAc)_2$ in 40 ml. MeOH contg. 0.2 ml. concd. NH_4OH. The soln. now shows the band of *mesobiliviolin* at 622 mμ. The soln. is a pure blue and shows intense red fluorescence. The soln. is poured into $CHCl_3$, washed with 2% HOAc to remove Zn, and then washed to neutrality. An unstable *mesobiliviolin II* (IV) can be extd. from the $CHCl_3$ soln. with 1% HCl. The $CHCl_3$ soln. is dried overnight with Na_2SO_4. On concg. the brown-violet soln. crystals of III are obtained. Left in the soln. is a violet violin, *mesobiliviolin III*, which cannot be extd. from $CHCl_3$ with 1% HCl, and which shows bands at 544 and 501 mμ. The crystals are filtered off, washed with very little $CHCl_3$, and recrystd. from pyridine. The pyridine soln. is dild. with H_2O and poured into $CHCl_3$. The aq. layer contains the pigment. Cautious addn. of HCl drives it into $CHCl_3$. The $CHCl_3$ soln. is extd. several times with 10% HCl to remove pyridine and the violin, then washed to neutrality, concd. till crystn. starts, and allowed to cool. Yield after 2 recrystns., is about 40 mg. The analysis fits the formula $C_{33}H_{38}N_4O_7$, m. (rapid heating) 240° (d.). III is easily sol. in pyridine, sparingly so in EtOH, $CHCl_3$, Me_2CO, EtOAc and Et_2O, and insol. in petr. ether and H_2O. III is likewise obtained from II in the absence of air, and so seems to be an isomerization product of IV. III cannot be extd. from $CHCl_3$ with 25% HCl, but goes into 50% H_2SO_4, returning to $CHCl_3$ on dilu. In ammoniacal soln. there is a band at 416 mμ. NaHg added to an alk. soln. of III destroys the yellow color, and a leuco compd. (V) can be extd. from the soln. by $CHCl_3$ after acidifying with HOAc. V quickly oxidizes in air, yielding a compd. which shows a band in the blue-green and intense green fluorescence with $Zn(OAc)_2$. To prep. *bilichrysin* (VI), 2.07 ml. alc. I soln. is added slowly, as above, to 62 mg. I in a soln. of 50 mg. $Zn(OAc)_2$, 30 ml. MeOH and 0.1 ml. concd. NH_4OH. The soln. of the *violin* (VII) Zn compd. is greenish and shows intense red fluorescence. The VII is extd. with $CHCl_3$ and allowed to stand for 3 days. The pigments are then extd. with 1% Na_2CO_3 and brought into Et_2O with tartaric acid. Use of 10% HCl removes the violins and leaves a yellow pigment in the Et_2O layer. The Et_2O layer is washed with H_2O, concd. and the residue recrystd. from MeOH, giving yellow needles. When $Zn(OAc)_2$ is added to a soln. of VI in the air, the bands of *biliviolin* Zn appear, with the stronger at 637.8 mμ, characteristic of protoviolins. This shows that the vinyl groups have not been affected during the prepn. A table differentiates the bile pigments and gives their characteristics. Conclusion: The chrysins contain one atom of O more than the verdins. Marcelle Schubert

The oxidation of pyrocatechol and 1,2,4-trihydroxybenzene by polyphenoloxidase. Harold Jackson. *Biochem. J.* **33**, 1452-9(1939); cf. Wagreich and Nelson, *C. A.* **30**, 8256⁷.—The oxidation of pyrocatechol (I) by polyphenoloxidase in the presence of $PhNH_2$ was reëxamd. The amt. of dianilino-*o*-quinone (II) formed diminished as the introduction of $PhNH_2$ into the oxidizing I was delayed; the total O absorbed remained const. at 3 atoms per mol. of I. The oxidation of 1,2,4-trihydroxybenzene (III) at pH 5.9 was catalyzed by polyphenoloxidase. In the presence

of $PhNH_2$, 2 atoms of O per mol. of III was absorbed; autoxidation under the same conditions required 4 atoms of O. The only product which could be isolated in both cases was a hydroxymonoanilinoquinone. These results do not support the theory that enzymic oxidation of I proceeds to hydroxyquinone, or that the formation of II takes place by the interaction of $PhNH_2$ with hydroxyquinone or any higher oxidation product of I than *o*-quinone. E. W. Scott 1

Factors preventing oxidation of ascorbic acid in blood serum. E. M. Mystkowski and D. Lasocka. *Biochem. J.* **33**, 1460–4(1939).—Natural protein-Cu complexes, such as are obtained from serum, acted as feeble catalysts in the oxidation of ascorbic acid by air, but since they also bind a certain amt. of Cu or Fe, they also protected the ascorbic acid from oxidation. Amino acids, and chlorides regardless of the cation, in addn. to serum proteins had an inhibitory action on the oxidation. E. W. Scott 2

Transamination in pigeon-breast muscle. Philip P. Cohen. *Biochem. J.* **33**, 1478–87(1939); cf. *C. A.* **33**, 7835[5].—Of 21 amino acids studied, *l*(−)aspartic acid (I) and *l*(+)alanine (II) were the most active in the formation of glutamic acid (III) from α-ketoglutaric acid (IV); *d,l*-α-aminobutyric acid and valine were slightly active, but none of the others was. Of a series of ketonic acids tested, oxaloacetic (V) and pyruvic (VI) acids showed the greatest activity in causing the disappearance of III. The results can be explained by assuming the existence of 3 enzyme systems which are concerned with the following reactions: III ⇌ IV, I ⇌ V, II ⇌ VI. By combining these systems the following may be brought about: IV + II ⇌ III + VI, IV + I ⇌ III + V, V + II ⇌ I + VI. The occurrence of the last reaction in pigeon breast muscle has not yet been conclusively demonstrated. Transamination in this tissue was inhibited by high concns. of cyanide. NaF, As_2O_3 and octyl alc. had slight inhibitory effects. Pyrophosphate, malonate, iodoacetate and bromoacetate had no effect. A no. of other amino compds. which were tested had no effect in transamination. The differences in these results from those reported by Braunstein and Kritzmann (*C. A.* **33**, 2916[5]) were explained by the failure of the latter to use a suitable control in their expts. E. W. Scott 3

The polysaccharide complex present in serum proteins and the effect of pepsin on serum protein fractions. L. F. Hewitt. *Biochem. J.* **33**, 1496–1505(1939); cf. *C. A.* **32**, 9122[1].—A series of digestions with pepsin and trypsin followed by acid acetone pptns. provided a simple method of isolating the carbohydrate complex. The properties of the polysaccharides present in seroglycoid and globoglycoid were studied. The results were all compatible with the view that these carbohydrates contain galactose-mannose-acetylhexosamine. Some nitrogenous material was present in the prepns. Very brief treatment of seroglycoid with pepsin gave a breakdown product similar to "serum mucoid." The latter which is never found in normal serum is possibly produced by disintegration of seroglycoid. E. W. Scott 4

Detoxication. III. The use of the glucuronic detoxication mechanism of the rabbit for the resolution of *d,l*-menthol. Richard T. Williams. *Biochem. J.* **33**, 1519–24(1939); cf. *C. A.* **33**, 2550[2].—The resolution was effected in 2 ways: (1) the NH_4 salts of the menthylglucuronides excreted in the urine after feeding *d,l*-menthol were fractionally crystd. and (2) the *l*-menthol was nearly all eliminated by refeeding the menthol excreted since the *l*-form was more easily oxidized in the rabbit and the remaining *d*-menthylglucuronide was easily purified by crystn. *d*-Menthol was obtained in about 10% yield. The excretion of conjugated menthol was complete in about 30 hrs. after a dose of 3 g. was given *d-Menthyl-β-d-gluconide* m. 120–2°, $[\alpha]_D^{25}$ 6.4° (*c* = 2 in abs. alc.) (*NH_4 salt* m. 200–2°, $[\alpha]_D^{25}$ 8.1° (*c* = 1 in H_2O)); *d-menthylphenylurethan* m. 112–13°, $[\alpha]_D^{25}$ 75.7° (*c* = 1 in $CHCl_3$); *d-menthyl-3,5-dinitrobenzoate* m. 153–4°, $[\alpha]_D^{25}$ 77.1 (*c* = 0.8 in $CHCl_3$). E. W. Scott 5

Metabolism of sulfur. VIII. Oxidation of the sulfur-containing amino acids by enzymes from the liver of the albino rat. Grace Medes and N. Gulezian. *Biochem. J.* **33**, 1559–69(1939); cf. *C. A.* **33**, 8251[6].—The enzymes (4) which were extd. from the livers were: cytochrome oxidase which oxidized cysteine to cystine and had no effect on methionine or cysteinesulfinic acid (I); an enzyme which oxidized the S of cysteine to inorg. sulfate (possibly only to the sulfinic acid stage); an enzyme which oxidized the S of I to inorg. sulfate; and an enzyme which oxidized cysteine to cysteic acid (according to iodometric titration). This last oxidation probably was the 1st step in the production of taurine. I was possibly an intermediate. **IX. The nonproduction of glycogen from cystine, cysteine and methionine and their partially oxidized derivatives.** Grace Medes and Italia Vitanza. *Ibid.* 1570–2.—Cystine, cysteine and methionine, fed to rats starved for 24 or 36 hrs. before receiving 0.0178 mol. equiv. of the compd. per sq. cm. body surface in 4 hourly portions, did not give rise to glycogen in the liver, as shown by analysis 1 hr. after the final feeding. Methionine sulfoxide, cysteinesulfinic acid and cysteic acid also did not cause glycogen deposition in the liver when they were fed. E. W. Scott 6

Cytochrome c as a carrier with the glucose-dehydrogenase system. John R. Hawthorne and Douglas C. Harrison. *Biochem. J.* **33**, 1573–9(1939).—Cytochrome c (I) in the presence of cytochrome oxidase prepns. acted as a carrier to bring about the aerobic oxidation of glucose by the glucose–dehydrogenase system. The cytochrome oxidase prepns. by themselves induced some oxidation of glucose in the presence of the dehydrogenase system, possibly because of cytochrome a and b present in the oxidase prepns. In acting as a carrier in this oxidation I was not directly reduced by the dehydrogenase–coenzyme systems but required for its reduction an addnl. factor which was present in heart muscle and in the cytochrome oxidase prepns. made from heart muscle. E. W. Scott 7

The hydrolysis of glucosaminides by an enzyme in Helix pomatia. A. Neuberger and Rosalind V. Pitt Rivers. *Biochem. J.* **33**, 1580–90(1939).—An enzyme ext. was prepd. from *Helix pomatia* which hydrolyzed specifically β-glucosaminides. It showed its greatest activity at 37.5° and pH 3.6. It hydrolyzed *N*-formyl and *N*-acetylglucosaminides, but had no action on the *N*-propionyl, *N*-butyryl and *N*-*p*-toluenesulfonyl derivs. or on nonacylated glucosaminides or glucosaminides which were completely O-substituted. It was possible to sep. the β-glucosidase and β-glucosaminidase in the *Helix pomatia* ext. E. W. Scott 8

The interaction between porphyrins and lipoid and protein monolayers. E. Stenhagen and E. K. Rideal. *Biochem. J.* **33**, 1591–8(1939).—It was shown that bilirubin and the capillary-active porphyrins strongly penetrate lipoid monolayers and that this penetration involved a weak polar interaction and was largely influenced by the interaction of the hydrophobic portions of the mols. Specific interaction was found to occur with amine monolayers, the strength of the interaction being independent of the capillary activity of the reactant. Protein films interacted and were tanned by the more active capillary-active porphyrins, but in some cases no adsorption of the porphyrins occurred in spite of strong reaction with amine films. This was due, in part at least, to polar interaction within the protein monolayer itself, as the reactivity of the amine group was negligible in mixed amino acid films, where strong polar attraction between the basic and acidic groups occurs. Electrophoresis expts. with human serum albumin and hemato- and proto-porphyrin indicated the absorption observed in these cases parallelled the absorption noted in films, suggesting that the same forces were operating. E. W. Scott 9

Hydrolysis of hyalurinic acid by bacterial enzymes. Karl Meyer, Gladys L. Hobby, Eleanor Chaffee and Martin H. Dawson. *J. Exptl. Med.* **71**, 137–46(1940).—An improved method is described for prepg. the enzyme which hydrolyzes the polysaccharide acid contained in vitreous humor, umbilical cord, synovial fluid and the mucoid phase

of group A hemolytic streptococci. Prepns. have been obtained from pneumococci, group A hemolytic streptococci, *Clostridium welchii* and from splenic tissue, which display the same sp. activity. The hydrolytic enzyme is not the same as that responsible for the lysis of pneumococci. In pneumococci and hemolytic streptococci, the major portion of the enzyme is bound to the cell structure; the enzyme from *Clostridium welchii* is assocd. with other carbohydrate-splitting enzymes in the culture medium and not with the bacterial cells. It is suggested that the disappearance of the mucoid capsules of group A hemolytic streptococci is due to enzymic hydrolysis of the acid polysaccharide. The relation between enzyme activity and the virulence and invasiveness of group A hemolytic streptococci is briefly considered. C. J. West

Serological tests for homologous serum proteins in tissue cultures maintained on a foreign medium. Karl Landsteiner and Raymond C. Parker. *J. Exptl. Med.* 71, 231–6(1940).—Connective tissue cells (fibroblasts) derived from skeletal muscle of 12-day-old chick embryos were cultivated for almost 8 months (35 weekly passages) in rabbit plasma and rabbit embryo tissue juice dild. with Tyrode soln. When fluids sepd. from these cultures were tested with immune precipitins developed against chicken serum, they gave pos. reactions which showed no tendency to diminish with an increasing no. of culture generations. Barring the intervention of unknown precipitable substances, these results indicate that connective tissue can produce proteins which are identical with, or closely related to, serum proteins. The expts. further demonstrated that tissues cultivated in a foreign plasma do not lose their species specificity. C. J. West

Practical model of the animal cell membranes. Harry N. Holmes. *J. Phys. Chem.* 43, 1151–3(1939).—It is shown how working models of animal cell membranes of double permeability can be prepd. A membrane permeable to water-sol. and also to fat-sol. substances is made by dissolving lecithin (1%) in common collodion solns. of cellulose nitrate. Good membranes of double permeability can also be formed by the addn. to collodion solns. of 1% of oleic acid, stearic acid, cholesterol, a 5 to 1 mixt. of lecithin and cholesterol, rosin, and similar substances. A collodion-lecithin sac contg. an emulsion of toluene in water contg. Na oleate as emulsifying agent is shown to be permeable to the toluene. L. Kolodny

Role of desoxyribosenucleic acid in cell division. T. Caspersson. *Chromosoma* 1, 147–56(1939).—Desoxyribosenucleic acid (I) appears necessary for cell division. An increase of nucleic acid occurred in acid nuclei deficient in nucleic acid during the prophase. Further study of the local synthesis of this high-polymeric material by ultraviolet absorption measurement in the single living cell was made to det. the quantity of nucleic acid during the various stages of mitotic prophase in the *Gomphocerus*. The results were against a direct correlation between nucleic acid synthesis and chromatid contraction. Since I was found localized in the reproductive cellular elements and to be present in large amt. before cell division, C. concludes that there is a correlation between these 2 phenomena. M. M. R.

Experiments on the enzymic splitting of *O*-acetylaneurin by cholinesterase. H. Süllmann and H. Birkhaüser. *Schweiz. med. Wochschr.* 69, 648–50(1939).—Acetylaneurin was split by exts. of human brain, but with less speed than was acetylcholine. Hydrolysis did not occur when acetylaneurin was subjected to horse serum rich in cholinesterase. Maurice M. Rath

Lipase action in mixts. of raw and pasteurized homogenized milk (Gould, Trout) 12. Review of org. and physiol. chemistry (Felix) 10.

Brimble, L. J. F.: A School Course of Biology: with Suggestions for Practical and Field Work. London: Macmillan and Co., Ltd. 470 pp. 6s.

Charles, (Brother H.): Biology. Milwaukee: Bruce Publishing Co. 408 pp. $1.72.

Szent-Györgyi, Albert v.: On Oxidation, Fermentation, Vitamins, Health and Disease. Baltimore: Williams & Wilkins Co. 109 pp. $2.00.

B—METHODS AND APPARATUS

GLENN E. CULLEN

Use of the glass electrode in the biological laboratory. Henry Francis Holden. *Australian J. Exptl. Biol. Med. Sci.* 16, 193–204(1938).—Suitable equipment is described for H-ion concn. detns. with the glass electrode when only small amts. of material are available. Methods of making small glass electrodes are described, and also an electrode chamber suitable for detns. on blood. B. C. P. A.

The isolation of α-phylloquinone (vitamin K from alfalfa) and the history of its discovery. P. Karrer, A. Geiger, R. Legler, A. Rüegger and R. Salomon. *Helv. Chim. Acta* 22, 1464–70(1939)(in German); cf. *C. A.* 33, 8191[6] —*Isolation of α-phylloquinone* (I): 30 kg. dried alfalfa powder is extd. with 40 l. boiling petr. ether (b. 40–60°). The ext., contg. about 400–600 g. solids, is evapd. to 20 l. Portions of 5 l. are dild. with 5 l. petr. ether. Finely powd. $ZnCO_3$ (total = 20 times the wt. of dry matter in the ext.) is added in small amts. with stirring and the mixt. is agitated for 2 hrs. If the supernatant liquid is still green, more $ZnCO_3$ is added until the soln. becomes reddish brown. An excess of $ZnCO_3$ results in a loss of I. After the $ZnCO_3$ has settled, the clear supernatant liquid is poured off, 5 l. petr. ether is added to the $ZnCO_3$ residue, the mixt. is stirred and the supernatant fluid is again poured off. The residue is filtered and washed with petr. ether until the washings are colorless. All the petr. ether solns. are combined, evapd. to 500 cc. and allowed to stand for 2 days at −10°. The colorless residue is filtered off and washed with petr. ether. The solvent in the filtrate is removed *in vacuo* on a water bath. The residue, a dark brownish red waxy substance, contg. 100,000–150,000 K units (Dam) per g., is subjected to mol. distn.; the portion coming off up to 150° contains practically all the vitamin K. The mol. distillate (II) usually contains about 200,000 units/g. It is liquefied by warming slightly and poured, with stirring, into 3–4 times the amt. of Me_2CO. The solid portion is filtered off; the filtrate is placed in an ice-box and filtered after 12 hrs. Evapn. of the filtrate to ⅓ its vol. results in a small crop of crystals which are removed. The Me_2CO is evapd. *in vacuo* and the remaining reddish brown oil (III) is taken up in 9 parts of petr. ether. A layer of dehydrated $MgSO_4$, 35 cm. high, is placed in adsorption tubes, 60 cm. high and 8 cm. in diam. First 350 cc. petr. ether is drawn into each tube and then 120 cc. of the petr. ether soln. of III dild. with an equal vol. of petr. ether. The column is washed with 800 cc. petr. ether and then with about 1500 cc. petr. ether contg. 10% benzene. This filtration through $MgSO_4$ removes 30% impurities. The solvent is evapd. and the residue (IV) is subjected to a chromatographic sepn. Layers of $ZnCO_3$, 40 cm. high, are placed in 27 tubes, 60 cm. high and 3 cm. in diam. Into each tube is drawn 50 cc. petr. ether and then a soln. of 1.5 g. IV in 50 cc. petr. ether. After washing with 150 cc. petr. ether and then 100 cc. petr. ether contg. 10% benzene, the chromatogram is developed. The portions of the columns having high extinction coeffs. ($E^{1\%}/1$ cm. at 248 mμ) are combined and subjected again to chromatographic sepn. on $ZnCO_3$. A prepn. of I which is chromatographically uniform is obtained after 7–8 such adsorptions. About 0.5 g. pure I can be isolated from 200 g. II, i. e., about 15–20% of its vitamin K content. Vitamin K from alfalfa (*C. A.* 33, 5448[5]) was the first pure prepn. of vitamin K isolated. Ruth Berggren

A new method for the determination of mucin in saliva. Lóránd Kesztyüs and Katalin Piribauer. *Magyar Orvosi Arch.* 40, 363(1939).—Mucin is removed from saliva with 20% HOAc. The N content of whole and mucin-free saliva is then detd. E. Borek

A micromethod for the determination of total, acid-soluble and lipin phosphorus contents of blood. Pál Dömösi. *Magyar Orvosi Arch.* 40, 287(1939).—The splitting of org. phosphates by dry fusion with KNO_3 and $CaCl_2$ is the new procedure. E. Borek

Estimation of blood sugar by the practitioner. H. R. Millar. *Brit. Med. J.* 1939, II, 1035–6.—A modification

of Folin and Wu's blood sugar method is described, whereby the use of the colorimeter is avoided. Simple dilution of the final colors in specially calibrated tubes and comparison with the naked eye gives results within ±10 mg. %. J. B. Brown

Blood preservation. The serum potassium of cadaver blood. John Scudder, Dorothy R. Corcoran and Charles R. Drew. *Surg. Gynecol. Obstet.* **70**, 48–50(1940); cf. *C. A.* **33**, 8653[3].—The av. concn. of human serum K, 35 hrs. after death, is 101 mg. % as compared to 17.2 in normal venous blood and 29.7 in the plasma of cardiac blood taken at the time of death. The increase is more rapid in cadaver blood than in blood stored in a refrigerator at 4°. J. B. Brown

Studies of liver function by means of Quick's hippuric acid test. J. G. Probstein and Sol Londe. *Ann. Surg.* **111**, 30–45(1940).—For Quick's liver function test (cf. *C. A.* **30**, 3493[8]) 4 g. of BzONa is superior to the recommended 6-g. dose. Estn. of the hourly output of hippuric acid for 4 hrs. permits an evaluation of the degree of impairment of the liver function. If the hippuric acid excreted in 2 hrs. represents 50% or more of the ingested BzONa, normal liver function is indicated. Rachel Brown

Metabolism of the isolated perfused cat brain. A. L. Chute and D. H. Smyth. *Quart. J. Exptl. Physiol.* **29**, 379–94 (1940).—A method of perfusing the isolated cat brain and an app. for recording continuously the O consumption of such a prepn. are described. Blood flows were 60–90 cc./100 g./min. at pressures of 120–150 mm. Hg. Flows of 45 cc./100 g./min. were incapable of maintaining cerebral function as judged by the presence of the corneal reflex. Oxygen consumption was 200–300 cc./100 g./hr. Oxygen usage was always in excess of that required for the complete oxidative removal of carbohydrate. Usage of both glucose and lactate were observed. The brain showed a predilection for the former. 32 references. Rachel Brown

A micromethod for the determination of alkapton in urine. V. Figura. *Atti accad. Lincei, Classe sci. fis., mat. nat.* **29**, 329–32(1939).—Alkapton in alk. soln. reduces $AgNO_3$ to AgO, which is redissolved in HNO_3 and titrated with NH_4SCN with ferric ammonium alum as indicator. To 1 cc. urine in a centrifuge tube add 5 cc. of a soln. made up of 50 cc. 20% $AgNO_3$ soln., 40 cc. concd. NH_4OH, and 10 cc. oxalic acid. After 5 min., add 5 drops of 10% $CaCl_2$ soln. In the presence of alkapton AgO is formed, which is carried down by the Ca oxalate also formed. Centrifuge the soln., carefully remove the liquid with a pipet, redissolve the AgO and titrate the soln. with 0.1 *N* NH_4SCN soln. Analyses of aliquot portions of a soln. indicate that results to within 0.5% are obtained on 1- 2-cc. samples of urine. A. W. C.

Isolation of desired qualities of radiant energy for biological experimentation. Loyd A. Jones and Clifton Tuttle. *J. Nutrition* **18**, 611–18(1939); cf. *C. A.* **24**, 1889.—Radiation chambers equipped with thermopiles and other equipment are described. C. R. Fellers

Comparison of the methods of Bang and of Rückert for the determination of fat. Mihály Kaszab. *Közlemények az Összehasonlító Élet- Kórtan Köréből* **27**, 182–8(1940).—Bang's method gave for blood serums of domestic animals free fat acids and lipoids 144.85- 212.34 mg. %; Rückert's method, 156.06–221.81 mg. %. The content of protein-bound fat was 37%, and that of lipoids 24% of the content of free fat acids, detd. by means of digestion by pepsin in the blood serums of horses and oxen. The greatest deviations of Rückert's method were observed in analyzing pig serums. The av. errors of the method were ±7.29% in detns. of total fats, ±3.91% for neutral fats and cholesterol and ±8.76% for phosphatides. For large nos. of detns., Rückert's method seems to be suitable. S. S. de Finály

Refractometric protein determinations in the blood serums of poultry. Mihály Szücs. *Közlemények az Összehasonlító Élet- Kórtan Köréből* **27**, 188–94(1940).—Detns. of total protein of blood serums of hen, duck, goose and turkey by the refractometric method were 5–15% higher than the detns. by the Kjeldahl method. Total proteins detd. by the Kjeldahl, the gravimetric and the refractometric methods, resp., were: for hen 4.13, 4.45, 4.89; for turkey 4.97, 5.13, 5.13; for goose 4.50, 4.73, —; for duck 3.84, 4.88, 5.12. The gravimetric and the refractometric methods, resp., gave for globulin: hen 2.12, 2.53; turkey 1.87, 2.18; goose 1.79, —; duck 1.62, 2.00; for albumin: hen 2.04, 2.36; turkey 2.76, 2.94; goose 2.85, —; duck 2.73, 3.13. S. S. de Finály

Experimental study of the stability of the Nessler reaction and its application to the photometric determination of nitrogen. Léon Gillo. *Bull. soc. chim. biol.* **21**, 1117–38(1939).—The Nessler reaction as used in biochem. detns. is discussed. The final mixt. should be at least 0.1 *N* in free NaOH to obtain the max. color. The presence of various salts, especially Na_2SO_4, promotes turbidity. The addn. of 1% of purified gum Senegal prevents turbidity, even in the presence of high concns. of Na_2SO_4. A method of purifying the gum is described. Extinction coeff. curves are given for photometric detns. with different light filters. L. E. Gilson

Submicrodetermination of phosphate ion. Christian Dumazert and Marcel Mourgue. *Bull. soc. chim. biol.* **21**, 1151–62(1939).—The prepd. sample contg. 10–180 γ P as phosphate is treated under specified conditions with acidified NH_4 molybdate soln. to ppt. the P as NH_4 phosphomolybdate. The ppt. is distd. with NaOH and the NH_3 in the distillate detd., by use of the microapp. and method previously described (*C. A.* **33**, 2845[1]). L. E. Gilson

Stabilization and determination of bilirubin in duodenal fluid. G. Barac. *Bull. soc. chim. biol.* **21**, 1163–70 (1939).—The addn. of 7.5 mg. % of ascorbic acid to an alk. soln. of bilirubin prevents destruction by the alkali and stabilizes the color, thus facilitating the colorimetric or photometric detn. HCHO, $Na_2S_2O_4$ and $Na_2S_2O_3$, used in the same manner, had no protective action. L. E. Gilson

Spectrum of bilirubin in alkaline media. A. Lambrechts and G. Barac. *Bull. soc. chim. biol.* **21**, 1171–80(1939).—The addn. of 200 mg. of ascorbic acid to a soln. of 5 mg. or more of bilirubin in 1 l. of 0.01 *N* NaOH stabilizes the color. The soln. shows a single strong absorption band at 430 mμ. L. E. Gilson

Analysis of biological compounds containing deuterium by interferometric refractometry. R. Jonnard. *Bull. soc. chim. biol.* **21**, 1185–93(1939).—A proposed method for estg. the relative amt. of the D isomer in an org. compd. utilizes the difference in *n* of solns. of known concn. of the compd. in pure H_2O and in heavy water of known D_2O content (20–40%). The interferometric refractometer of J. is used. L. E. Gilson

Simplified method of obtaining acid-precipitable lipide-protein combinations (cenapses) from serum. Michel A. Macheboeuf and L. Dizerbo. *Compt. rend. soc. biol.* **132**, 268–71(1939).—The serum albumin was sepd. into 6 fractions. All contained considerable lipides. **Precipitation of serum albumins and the lipides which accompany them by ammonium sulfate at different pH values.** M. A. Macheboeuf and J. Duboy. *Ibid.* 272–4.—With the $(NH_4)_2SO_4$ concn. at 400 g./l. the albumin pptd. at pH 5.2 contained 1.4% or less of lipide, that pptd. at pH 3.6 contained 19% and that pptd. at pH 2.6 contained 30% lipides. L. E. Gilson

A rapid micromethod for determining diodrast and inorganic iodide iodine in blood and urine. H. L. White and Doris Rolf. *Proc. Soc. Exptl. Biol. Med.* **43**, 1–7(1940).—The sample is digested in an acid soln. of $KMnO_4$ to oxidize all I to iodate and destroy org. matter. The excess $KMnO_4$ is then reduced by $NaNO_2$ and the excess $NaNO_2$ destroyed by urea. The iodate is titrated with a 0.0004715 *N* $Na_2S_2O_3$ soln. in presence of an excess of KI. Complete details are given. L. E. Gilson

Photoelectric study of the Liebermann-Burchard reaction and its significance in the determination of cholesterol. Wm. S. Hoffman. *Proc. Soc. Exptl. Biol. Med.* **43**, 38–42(1940).—The color changes that take place

during the reaction and the influence of time, temp. and type of color filter used on the accuracy of the detn. are discussed. L. E. Gilson

Urinary excretion of vitamin B_6 in the rat. John V. Scudi, Harold F. Koones and John C. Keresztesy. *Proc. Soc. Exptl. Biol. Med.* **43**, 118–22(1940).—A colorimetric method for detg. vitamin B_6 in urine is described. At high dose levels (10 mg. or more per kg.) 50–70% is excreted by both normal and deficient rats. L. E. G.

Production of renin by constricting the renal artery of an isolated kidney perfused by blood. K. G. Kohlstaedt and Irvine H. Page. *Proc. Soc. Exptl. Biol. Med.* **43**, 136–40(1940). L. E. Gilson

Clinical detection of barbiturates in urine. F. Servanton. *Bull. trav. soc. pharm. Bordeaux* **77**, 221–8 (1939).—A crit. review of methods. S. W. G.

The determination of the pH of human milk with alizarin. M. E. Kayser. *Deut. med. Wochschr.* **65**, 1476–7(1939).—In prepg. human milk powder it is necessary to know its pH in order to avoid the use of milk with an abnormal degree of acidity. Alizarin offers a convenient colorimetric procedure for this purpose. Arthur Grollman

The diagnostic value of carcinoma reactions. VI. Reexamination of the albumin A reaction of Kahn. K. Hinsberg, R. Merten and K. Mucke. *Z. Krebsforsch.* **49**, 371–4(1939); cf. *C. A.* **33**, 2974[2].—It is maintained by Kahn (*Verh. intern. Krebs-Kongr., Madrid* **1933**, II) that by means of a nephelometric method a decrease in albumin A (the albumin fraction most difficult to ppt.) can be demonstrated in the serum of carcinoma patients. Reëxamn. of the work makes it seem improbable that the nephelometric method is a suitable method to indicate albumin shifting, even if such shifting were specific for cancer. Nephelometric measurements are only reliable when dealing with ppts. of particles of equal size, and with albumin solns. this is not the case. **VII. The diagnostic value of the ether test for the differentiation of icteric carcinoma and noncarcinoma serums.** D. Albers and R. Merten. *Ibid.* 375–8.—Ascoli (*C. A.* **30**, 3059[2]) has maintained that serums made artificially icteric by the addn. of bilirubin or bile after drying on filter paper do not give up the bilirubin when treated in the cold with ether if the serums are normal or pathologic but noncarcinomatous, while serums from carcinoma cases give up the bilirubin readily. While checking up on the various carcinoma reactions, all icteric serums have been tested with the ether test to see if carcinomatous icteric serums could be differentiated from noncarcinomatous icteric serums. Twenty of the 22 carcinomatous icteric serums gave pos. tests, while all 9 noncarcinomatous icteric serums gave neg. tests. Harriet F. Holmes

The influence of light on the determination of alcohol in blood according to the method of Widmark. Ludv. Hallén-Paulsen. *Tids. Kjemi Bergvesen* **19**, 61–2(1939). —The influence of ultraviolet (quartz-mercury lamp) light on $N/20$ $K_2Cr_2O_7$ in H_2SO_4 as used for the alc. detns. is shown to cause reduction which increases with intensity of radiation. Irradiation by sunlight in 228 min. caused a reduction which was equiv. to 2.89% alc. in blood. It is pointed out that care must be taken in alc. detns. in blood to avoid too strong irradiation of the soln. H. Kringstad

Interfering substances in the alcohol determination in blood according to Widmark's method. Ottar Dybing, Klaus Hansen and G. Rasch. *Tids. Kjemi Bergvesen* **19**, 114–17(1939).—By statistical analysis a law is derived by which the error of alc. detns. in blood can be calcd. H. Kringstad

Estimation of purified papilloma virus protein by infectivity measurements. W. Ray Bryan and J. W. Beard. *J. Infectious Diseases* **65**, 306–21(1939).—A procedure for turbidity measurements of the purified papilloma virus protein by means of the photoelec. colorimeter and the correlation of the results with protein detd. directly by N analyses are described. An accurate method for the estn. of infectivity assocd. with the virus protein was found in the statistical study of the relation of protein inoculated to the incubation period of induced lesions. The inoculation of decreasing amts. of protein resulted in the appearance of lesions after proportionately long incubation periods. The high degree of correlation of protein and incubation period was shown by the high value of the correlation coeff. and its small standard error. Julian H. Lewis

The effect of iodine and mercury on amino nitrogen values with nitrous acid. A. B. Kendrick and Martin E. Hanke. *J. Biol. Chem.* **132**, 739–51(1940); cf. *C. A.* **31**, 1836[5].—By the addn. of iodide, the HNO_2 amino N values of cystine and glycine become theoretical by the volumetric as well as the manometric method in the absence as well as in the presence of Hg. $(AcO)_2Hg$ lowers the amino N value of glycine to the theoretical, while Hg lowers it from 106 to 103%. With cystine both cause marked increases from 108 to 140% or more. Cystine and glycine form considerable CO_2 during the HNO_2 reaction, the amt. from glycine being slightly lowered and that from cystine considerably increased by addn. of iodide. CO_2 formation from glutamic acid is nearly zero The authors prefer the interpretation that added I oxidizes some abnormal reducing groups in deaminizing cystine and glycine and this prevents the reduction of HNO_2 by these groups which otherwise cause formation of extra N_2 (cf. Dunn and Porush, *C. A.* **33**, 3406[1]). In both the volumetric and manometric methods the KI should be dissolved in, and added with, the nitrite instead of the glacial AcOH. A. P. Lothrop

The spectral analytical determination of metals in microscopic preparations. Walther Gerlach. *Spectrochim. Acta* **1**, 168–72(1939).—The use of high-frequency excitation for the analysis of biol. prepns. has certain advantages but is not sufficiently sensitive for the detection of minute traces of heavy metals. Minute samples, scraped from microscope slides into a small cavity on a carbon electrode impregnated with pure NaCl, when excited in an interrupted arc and photographed with a quartz spectrograph will disclose traces of metals. The sensitivity appears to be 100 times that of high-frequency excitation. Analyses of liver sections and gum tissue are given as examples. W. F. Meggers

The diazo reaction. I, II, III. Maffo Vialli and Vittorio Erspamer. *Arch. fisiol.* **39**, 1–19, 20–32, 33–41(1939).—The diazo reaction was applied in acid and alk. mediums to a large no. of substances and the color reactions obtained were tabulated. The tests included a variety of aliphatic and aromatic compds. and exts. from animal tissues. Besides sulfanilic acid, reagents contg. *p*-nitroaniline, *p*-toluidine and benzidine were used, making use of org. solvents such as BuOH. The modification introduced by Hanke and Koessler, of adding H_2NOH, was also investigated. This latter method stabilized the color with glucose, carbosil and adrenaline. A. E. M.

A one-hour renal condition test. Wm. G. Exton and Anton R. Rose. *Am. J. Clin. Path.* **10**, 73–96(1940).—For 15 hrs. preceding the test take no medicine or alc. and keep the water intake as low as possible. For the preceding 3 hrs. take no liquid at all. Empty the bladder and one hr. later empty the bladder again and preserve the urine for examn. On this sample det. sp. gr., vol. or rate of excretion, rate of excretion of albumin, urea, chloride, formed elements, casts, etc. 17 references. John T. Myers

Double pipet for nonprotein nitrogen and sugar determinations. Thaddeus J. Domanski. *Am. J. Clin. Path., Tech. Suppl.* **4**, 16–18(1940).—The pipet delivers 2 cc. between the 2 upper calibration marks and a remaining 5 cc. is delivered when the pipet is blown out. John T. Myers

A modified Folin-Malmros micro blood glucose determination. Jonas Kamlet. *Am. J. Clin. Path., Tech. Suppl.* **4**, 20–4(1940). Cf. *C. A.* **23**, 4492. J. T. Myers

Some new methods of investigation applied in biological sciences. R. Sterckx. *Ann. zymol.* **6**, 337–54(1939).—Attention is drawn to the electronic microscope, to recent developments in radiophysiology and to work on D and

heavy water, from the standpoint of their value in biol. investigations. A. Papineau-Couture

Determination of ascorbic acid in the presence of hemoglobin. Rudolf Lemberg and John W. Legge. *J. Proc. Roy. Soc. N. S. Wales* **72**, 62–8(1938).—The rapid loss of ascorbic acid (I) occurring in a soln. of oxyhemoglobin (II) during pptn. of proteins is due neither to a reaction between I and II, nor to an oxidation by O_2 catalyzed by the pptn. of the acid hematin-denatured protein. It is caused by the O set free at the moment II is pptd. by HPO_3 in the presence of I. The oxidation can be prevented by forming a CO-hemoglobin or by reducing the II and carrying out the pptn. under anaerobic conditions. A small amt. of I is adsorbed on denatured protein in a concd. soln; however, this varies up to 10% of the total I oxidized. H. J. Prebluda

Peroxidase reaction. CXVIII. Relation between peroxidase-positive granules and Giemsa-stained granules of leucocytes after the administration of morphine hydrochloride. Akira Sato and Saburo Kuribayasi. *Tôhoku J. Exptl. Med.* **36**, 583-9(1939); cf. *C. A.* **34**, 2050[9].—The percentage of cells with strongly peroxidase-pos. granules among pseudoeosinophile leucocytes increased rapidly and reached the max. 2 days after the first administration of morphine-HCl. Then it showed a decrease and approached the initial on the 5th day of expt. The percentage of the cells with Giemsa-stained granules among pseudoeosinophile leucocytes increased in no. and reached the max. 5–6 days after the first injection of morphine-HCl. It decreased and approached the initial on the 10th day of expt. The increase of peroxidase-pos. granules has nothing to do with the increase of the Giemsa-stained granules. The former is the result of the effect of morphine on cerebral hemispheres, while the latter is the manifestation of the effect of the alkaloid on the organism. **CXIX. Arakawa's reaction and vitamin C content of human milk. 3. Are the methods for determination of vitamin C reliable?** Siroku Isono. *Ibid.* 590–602; cf. *C. A.* **33**, 8275[7].—Expts. were performed to test the accuracy of Harris and Ray's method for vitamin C detn. No definite conclusions were reached. From this work the question whether the difference of the vitamin C-like substance between Arakawa-pos. and -neg. milk is the difference of vitamin C itself or vitamin C plus some other substance remains unsolved. The author believes that it is not altogether satisfactory to rely on animal experimentation for the purpose of assaying the vitamin C which may remain undetd. by Harris and Ray's method. (*C A.* **27**, 4280, 4564). B. Prescott

Application of the enzymic method of ascorbic acid determination. E. R. Kratinova. *Biokhimiya* **4**, 220–8 (1939).—The enzymic method, which excludes all reducing substances other than ascorbic acid, agrees with the direct titration method for the ascorbic acid content in the adrenals, testes and skin of rats and guinea pigs. During the months of May, Sept. and Oct., the liver and spleen of these animals contain non-ascorbic acid-reducing substances. At this period, it is preferable to employ the enzymic method for the detn. of ascorbic acid. H. Priestley

The methods for vitamin B_2 determination in vegetable materials. K. L. Povolotskaya. *Biokhimiya* **4**, 327–35 (1939).—The best method at present available is that of Emmerie (*C. A.* **30**, 6403[2], 7193[8]), slightly modified by using 3 successive adsorptions on PbS and elution of each portion of the ppt. with 3 portions of aq. pyridine. H. Priestley

Photocolorimetric determination of vitamin D. V. L. Solyanikova. *Biokhimiya* **4**, 483–91(1939).—The Tortelli-Jaffé reaction, which is the most sp. one for vitamin D, yields an absorption spectrum with bands at 545–550 and 590–600 mμ. The reaction obeys Beer's law, and may, therefore, be used for the quant. photocolorimetric vitamin D detn. H. Priestley

Phenol granulation of the leucocytes and its staining with specific lipoid stains (Sudan). P. P. H. de Bruijn. *Acta Neerland. Morphol.* **2**, 321–44(1939).—**Granulation was formed in the neutrophile leucocytes and monocytes** of human blood by the action of phenol compds. as α- and β-naphthol, resorcinol and carbolic acid. The phenol granulation is stained with specific lipoid stains and basic dyes. The phenol action is based on a splitting of a previously invisible, protein-lipoid complex present in granular form. This splitting results in a change in the refraction of light of this complex which makes the granulation visible and also makes the granulation specific for staining. Maurice M. Rath

Urinary excretion of calcium acetylsalicylate. F. Dellamartina. *Schweiz. med. Wochschr.* **69**, 742–4(1939).—In normal subjects 0.5 g. Ca acetylsalicylate, taken orally, was completely excreted in the urine within 12 hrs. When excretion is delayed, a pathol. process is indicated. Maurice M. Rath

Reducing substances in the blood plasma of rheumatisants. Rene Dandurand, C. Wesler Scull and Ralph Pemberton. *J. Lab. Clin. Med.* **25**, 348–53(1940).—Details are given of a slightly modified procedure of the method of Polonovski and Warembourg (*C. A.* **28**, 2742[5]) for the estn. of substances in blood plasma that reduce chromic acid. The index chromic total (I. C. T.), the index chromic glucose (I. C. G.) and the index chromic residue (I. C. R.) were detd. on the fasting blood plasma of 55 patients with chronic arthritis of various types and on a few normal individuals. Further detns. of these levels were made on the plasma of 17 subjects in this series following the administration of glucose by mouth. The subjects were classified into atrophic, hypertrophic, mixed arthritis, fibrositis and miscellaneous rheumatoid groups. The blood plasma of rheumatisants presents deviations from normal in the direction of an excess of reducing substances other than glucose. The distribution of reducing materials in the blood of these patients following administration of glucose supports the view that when the rate of removal is delayed the disturbance is not one of specific interference with the metabolism of glucose, but is probably referable to a circulatory mechanism. Howard W. Robinson

The determination of pH values of biologic fluids. I. Albert Glaubiger and K. Geo. Falk. *J. Lab. Clin. Med.* **25**, 369–76(1940).—The pH values (25°) of buffer solns., bacteriol. media and biol. products were detd. by routine colorimetric procedures (Hellige color disk comparator method, cf. U. S. 2,050,608 (*C. A.* **30**, 6611[7]), and the method employing a comparator block with Sörensen's standard buffer solns. and indicators (Clark, Detn. of H Ions, *C. A.* **21**, 3328) and the electrometric method (MacInnes-Belcher glass electrode, *C. A.* **27**, 2848, and sat. calomel electrode in conjunction with the Young electron ray meter). For most of the test solns. the colorimetric values agree well within ±0.3 pH units with the electrometric values. The effects of diln. with water or saline on the pH values of the various specimens are given. Howard W. Robinson

The determination of acetylsulfapyridine. I. John V. Scudi and Harry J. Robinson. *J. Lab. Clin. Med.* **25**, 404–8(1940).—Acid hydrolysis of acetylsulfapyridine produces cleavage of both the Ac and the sulfonamide groupings. The liberated sulfanilic acid after diazotization couples much more slowly with dimethylnaphthylamine than sulfapyridine. This retardation causes variable results when the method of Marshall (*C. A.* **32**, 8466[7]) for the detn. of acetylsulfanilamide is applied to the estn. of acetylsulfapyridine. Alk. hydrolysis does not cleave the sulfonamide grouping; therefore the retardation in the coupling rate is eliminated. Acetylsulfapyridine in known amts. was added to 25 normal urine specimens and subjected to alk. hydrolysis. An av. recovery of 103% (±2, max. deviation 5%) was obtained. For blood acid hydrolysis was employed since some filtrates developed a yellow color during alk. hydrolysis. In applying the method of Marshall, it was found that 0.5 cc. of 8 *N* HCl added to 10 cc. of blood filtrate contg. a known amt. of acetylsulfapyridine produced complete coupling within 60 to 70 min. The excess acid was neutralized with 0.7 cc. of 4 *N* NaOH before replacing water of evapn. The hydrolysis was incomplete when 4 *N*

HCl was used. In blood a recovery of 92% (±2%) was obtained by using acid hydrolysis. II. *Ibid.* 409–10.— The detn. of acetylsulfanilamide, with *N*-(1-naphthyl)-ethylenediamine dihydrochloride (*C. A.* **33**, 5017[4]) as the coupling component, has been applied to the detn. of acetylsulfapyridine. Two variations in the method of Marshall were introduced: an increase of acid (8 *N* HCl) for the hydrolysis of blood filtrates, and an alk. hydrolysis for urine. An av. recovery of 96% was obtained in a series of 13 blood filtrates in which concns. of 4, 6, 10 and 16 mg. % of acetylsulfapyridine were present. An av. recovery of 100% was obtained from 16 normal urine samples to which acetylsulfapyridine had been added in concns. of 20, 25, 30 and 40 mg. %. H. W. Robinson

A method for rapid determination of magnesium in body fluids and some preliminary results on clinical material. Benedict Cassen. *J. Lab. Clin. Med.* **25**, 411–13(1940).—A spectrographic procedure that is more suitable for routine detns. than the method of Thomson and Lee (*C. A.* **31**, 4688[4]) is developed. The dild. body fluid soln. is atomized by a fine glass spray jet directed into and on the surface of C spark electrodes. The pressure for the operation is supplied by an O tank. An exposure is made on an Eastman O-III ultraviolet plate in a small quartz spectrograph; the density of the 2795.5 line is detd. with a Hartmann Comparator. The method of calibration is described. The normal whole blood values are 6 to 7 mg. per 100 cc., the plasma values 3 to 4 mg., and the cerebrospinal fluid av. value is 3 mg. The values show a tendency to be slightly higher than those reported as detd. by chem. methods. Satisfactory results were obtained on oxalated blood, and on plasma without removal of protein. Howard W. Robinson

A microdiffusion method for the estimation of acetone. S. C. Werch. *J. Lab. Clin. Med.* **25**, 414–20(1940).— The method employs the "Conway unit" (*C. A.* **27**, 3857) and the acetone is estd. by observing the time necessary to cause pptn. of Nessler's soln. From expt'l. results the relationship of concn., temp. and time is incorporated in the formula: $D = 179\ t^2/(24° - \Theta)^2$ where D = diln., t = time and Θ = temp., and for convenience a monographic chart is constructed. The method is applied to specimens of urine and blood. Howard W. Robinson

The use of honey as a levulose-tolerance test. J. B. Greco. *J. Lab. Clin. Med.* **25**, 420–3(1940).—Levulosemia curves were obtained on 10 normal persons, each of whom had received 100 g. of honey (equal to 40 g. of levulose) after fasting for at least 8 hrs. Levulose values in the blood (Roe method, *C. A.* **29**, 1126[9]) were zero when honey was given, 6 to 11 mg. % one hr. later, 4.0 to 9.5 mg. % 2 hrs. later, 2 to 4 mg. % 3 hrs. later. The use of honey is recommended as a levulose-tolerance test for the examn. of hepatic function because the results agree with those of Scott (*C. A.* **29**, 5874[2]) who used pure levulose; honey in the dose administered is well tolerated and there is no evidence of vomiting, nausea or diarrhea which is customary in the use of levulose; and also it is much cheaper than pure levulose. In 5 cases the total sugar concn. was detd. (Hagedorn-Jensen method, *C. A.* **17**, 2721) on blood secured at intervals so that the glucemic curve could be calcd. from the difference of the 2 curves. Howard W. Robinson

Determination of nicotinic acid in urine. Leo Schindel. *J. Lab. Clin. Med.* **25**, 515–16(1940).—Creatinine yields a red color with dinitrochlorobenzene in alk. soln. which is proportional to creatinine concn. On diln. of the soln. the shade changes from purple to orange. This substance may cause an error in the detn. of nicotinic acid in urine with 2,4-$(O_2N)_2C_6H_3Cl$. Cf. Vilter, Spies and Mathews, *C. A.* **33**, 5426[8]. Howard W. Robinson

An improved method for the iodometric determination of pyruvic acid. G. A. Schrader. *J. Lab. Clin. Med.* **25**, 520–6(1940).—The essential improvements are the addn. of an excess of 0.01 *N* I prior to liberation of pyruvate-bound bisulfite with $NaHCO_3$, a decrease in the amt. of bisulfite with a consequent decrease in amt. of 0.1 *N* I and in total vol. of soln., and the use of 0.01 *N* $Na_2S_2O_3$ which permitted a more accurate adjustment of the end point prior to and after the liberation of pyruvate-bound bisulfite. By the method 0.10 to 5.0 mg. of the acid can be accurately detd. The method was applied to rat urine and intestinal contents after the administration of pyruvate (nearly neutralized Na salt) to the animal. Cf. Clift and Cook, *C. A.* **27**, 2466. H. W. R.

Prothrombin time determination. Orville R. Kelley and W. E. Bray. *J. Lab. Clin. Med.* **25**, 527–30(1940).— The method is essentially that described by Quick (*Am. J. Med. Sci.* **190**, 501(1935)) with modifications designed to make it more suitable as a routine clinical lab. procedure. The prepn. of the thromboplastin, the prepn. of blood and the technique of the prothrombin time detn. are given in detail. The av. prothrombin time of the blood of 100 normal adults was 23 sec. which is the same as that reported by Quick. Howard W. Robinson

Purification of mare gonadotropic hormone. Harold Goss and H. H. Cole. *Endocrinology* **26**, 244–9(1940).— Expts. are given on the purification of the gonadotropic hormone of mare serum. The very potent serum of ponies and also the less potent horse serum were used. If the first 70% Me_2CO ppt. obtained by the Cartland-Nelson procedure (*C. A.* **31**, 6310[8]) is redissolved in 50% Me_2CO, pH 6–7, there is a 2-fold purification. When this 50% Me_2CO soln. of the hormone is further fractionated, by increasing the acidity in steps, a very potent fraction comes out between pH 5.5 and 4.5, which contains 4000–7000 rat units/mg. solids. At pH 6.0 the hormone begins to ppt. at 52.5% Me_2CO concn. (by vol.) and is completely removed at 60% concn. Cf. *C. A.* **27**, 763; **29**, 8082[9]. F. S.

The quantitative separation of the skeleton of small animals. V. Subrahmanyan, J. Duckworth and W. Godden. *Biochem. J.* **33**, 1421–4(1939).—A proteolytic method, employing papain or trypsin, is described for sepg. the entire skeleton of the rat for the estn. of Ca, Mg and P. E. W. Scott

Biological synthesis of hippuric acid in vitro. Henry Borsook and Jacob W. Dubnoff. *J. Biol. Chem.* **132**, 307–24(1940).—A tissue slice technique for the study of the synthesis of hippuric acid (I) and a micromethod for detg. 3 γ of I in 1–4 cc. of soln. are described. Guinea pig, rabbit and rat kidney and liver tissues synthesize I from BzOH and glycine. Dog kidney, but not liver, tissue forms I. Of 23 amino acids and amides only glycine formed I in the presence of BzOH and rat liver slices. I is not formed by macerated tissue or by intact tissue poisoned by toluene or KCN. Intact rat liver slices poisoned by KCN do not hydrolyze I. These results are in accord with deductions from the thermodynamic data which indicate that the synthesis of I is attended by a gain in free energy, and that it must be coupled with an energy-donating reaction, and cannot be simply the reverse of hydrolysis. The equil. consts. at 25° and 38° for the reaction I + H_2O = BzOH + NH_2CH_2COOH were calcd. The results are discussed with reference to the hydrolysis and synthesis of I in the whole animal (dog). D. S. S.

Use of the Feulgen reaction in cytology. I. Effect of fixatives on the reaction. B. B. Hillary. *Botan. Gaz.* **101**, 276–300(1939).— Expts. *in vitro* with agar blocks impregnated with nucleic acid show that the Feulgen nuclear stain gives 2 types of time curves depending on the presence or absence of chromic acid in the fixative. Chromic acid produces the type of staining curve with the prolonged max. Tannins have the same effect as chromic acid except in the presence of formalin. For a satisfactory stain hydrolysis for 5 min. with any of the regularly used cytological fixatives is sufficient. J. T. Sullivan

A method and apparatus for perfusing gastrocnemius muscle, with spinal roots, gangliated cord and blood vessels intact, and its applications. Syotin Haku. *J. Chosen Med. Assoc.* **29**, 2075–102 (German abstr. 132–5) (1939). S. Tashiro

Mounting-media with a high index of refraction. Lucien Perruche. *Bull. soc. franç. microscop.* **7**, 142–4 (1938).—The properties of a no. of media for biol. and mineralogical use are described. W. C. Tobie

Quantitative test for biotin and observations regarding its occurrence and properties. Esmond E. Snell, Robert E. Eakin and Roger J. Williams. *J. Am. Chem. Soc.* 62, 175–8(1940); cf. *C. A.* 34, 1050³.—A sensitive and accurate assay for biotin (I) is described which involves the growth of a strain of *Saccharomyces cerevisiae* from a small seedling. Under the test conditions the response of this organism to I is quant. within a concn. range from 0.00002 to about 0.001 γ of I. Assay results on crude exts. agree well at different levels within this range and the curves obtained are very similar to those obtained with pure I. The following I contents are reported (γ per g.): cane molasses, Hawaiian 2.7, Cuban 1.7, beet molasses 0.06–0.9, liquid urine 0.09, urine solids 2, liquid whey 0.12, whey solids 2.5, egg white 0.05, egg yolk 0.37 (autolyzed 24 hrs. 0.35), yeast (moist, autolyzed) 0.13, Beacon dog meal 0.53, casein, tech. 0.125, casein, purified 0.002, potato 0.010, autolyzed liver 3.89. The effectiveness of I under the conditions of assay depends to a large extent on the presence of vitamin B_6 (and of β-alanine) in the medium. I in liver concentrates is destroyed by HNO_2 at a rate which indicates that it may be an α-NH_2 acid. C. J. West

Detn. of CH_2O in protein solns. (Alcock, Otto) 7. Resazurin test for detecting mastitis (Russell, *et al.*) 12.

Osgood, Edwin E.: A Textbook of Laboratory Diagnosis with Clinical Applications for Practitioners and Students. 3rd ed. Philadelphia: P. Blakiston's Son and Co. 676 pp. $6.00.

C—MICROBIOLOGY

LAWRENCE H. JAMES

The filtrable tubercle bacilli. Yosio Miyazima. *Oriental J. Diseases Infants* 24, 25-9(1938)(in English).—The effects of treating guinea pigs with filtrable tubercle bacilli and with the nonacid-fast tuberculins (I) prepd. from them were compared with those produced by the regular tuberculin (II). I was markedly resistant to ultraviolet light. Pepsin and trypsin destroyed the active material in I in 8 hrs.; the activity of II was destroyed in 12 hrs. by pepsin and in 8 hrs. by trypsin. The active material of both I and II was adsorbed by animal charcoal in 3 hrs. Ruth Berggren

The effect of some fungi upon each other. E. Rennerfelt. *Svensk Botan. Tid.* 32, 332–45(1938)(in German).—*Penicillium rugulosum* (I) was cultured in nutrient solns. (salts + agar) contg. 20 g. carbohydrate/l. The color of the underside of the mycelium varied with different nutrients. The radial growth of I was fastest in media contg. malt ext. Since both the source of C and the inorg. salts influence the effect of one fungus culture upon another, the salts were kept as const. as possible. A suspension of *Cadophora fastigiata* (II) in agar was inoculated with a piece of the mycelium of I (cultured in glucose + agar). The color of the underside of the mycelium of I grown in the presence of II varied with different carbohydrates and the amount of inoculum. The growth of I was strongly inhibited and the color intensified in the presence of II. The agar surrounding I showed a "free zone," in which the growth of both fungi was suppressed except for a few stunted red mycelia of II. This zone was most distinct after 6–8 days of growth; at the end of 10 days it was 2–3 mm. wide in media contg. glucose, levulose or maltose, indistinct in media contg. sucrose, lactose or galactose and, due to the rapid growth of I, absent in media contg. malt ext. The effect of I on some Torulopsideae (*Rhodotorula glutinis* (III), *Torulopsis candida* (IV) and *Geotrichoides* No. 103 (V)) in cultures contg. tech. glucose was also studied. The observed phenomena depend on the ability of I to form bios growth substances and perhaps also A-growth substances. The differences in the effects of these growth substances upon the other fungi depend partly upon the extent to which these fungi can grow in synthetic nutrients. II and IV, which develop poorly in synthetic nutrients, are markedly influenced by the bios growth substances, while III and V, which grow fairly well in artificial nutrients, show no acceleration in development. The growth of the II mycelium was markedly inhibited; of the Torulopsideae, a faint inhibition was noted only in IV. The colors which appeared in mixed cultures were striking. In II and usually also in I the colors became darker, but in III the carotene pigment was destroyed. After varying intervals I overgrew the other fungi. II could inhibit the growth of I to a greater extent than the Torulopsideae. R. B.

The action of radium emanation on Brucella. M. Azzariti. *Pathologica* 31, 534–5(1939).—Ra emanation shows a germicidal action and dissociate microorganisms of the *Brucella* group, and particularly *B. abortus*. G. A. Bravo

Mercuric chloride, potassium mercuric iodide and Harrington's solution in skin disinfection. Behavior and uses. Philip B. Price. *Surg. Gynecol. Obstet.* 69, 594–601(1939).—$HgCl_2$, K_2HgI_4 and Harrington's solution behave similarly as skin disinfectants, each acting only as a skin antiseptic. In each case a film forms on the skin which is resistant to further disinfection and under which bacteria multiply. Ammonium sulfide removes this film, allowing subsequent disinfection in the underlying layers of skin. J. B. Brown

Studies on the chemical sterilization of surgical instruments. I. A bacteriological evaluation. E. H. Spaulding. *Surg. Gynecol. Obstet.* 69, 738–44(1939).—The bactericidal action of 7 common chem. sterilizing solns. was detd. on 8 species of sporulating bacilli. J. B. Brown

Action of sulfanilamide on mastitis streptococci in vitro. J. O. Heishman and W. T. Miller. *J. Am. Vet. Med. Assoc.* 96, 176–9(1940).—Some strains of Lancefield group B streptococci survived concns. of sulfanilamide of 800 mg. per 100 cc. for 14 hrs. and 200 mg. for 72 hrs. at 38.5°. The results were influenced by the type of medium used. The bactericidal action was enhanced as the temp. was raised. No correlation was noted between the *in vivo* and *in vitro* action of sulfanilamide. R. Brown

The proteolytic enzymes of Vibrio cholera and Vibrio El Tor. H. Beeuwkes. *A. van Leeuwenhoek J. Microbiol. Serol.* 6, 48–55(1939–40).—See *C. A.* 33, 4288⁹. A. D.

Silicosis and type III pneumococcus pneumonia; an experimental study. Arthur J. Vorwald, Anthony B. Delahant and Morris Dworski. *J. Ind. Hyg. Toxicol.* 22, 64–78(1940).—Silica added to blood-broth culture has no effect on growth of type III pneumococci. Silicotic rabbits showed no unusual susceptibility to type III pneumococcus infections; the disease runs its normal course; from the few cases observed, silicosis may actually enhance the resistance of the rabbit to type III pneumococcus infection. A. L. Elder

Resistance of Endamoeba histolytica cysts to chlorine in aqueous solutions. William S. Stone. *Am. J. Trop. Med.* 17, No. 4(1937); *U. S. Pub. Health Eng. Abstracts* 18, W, 97(Aug. 13, 1938).—When a sufficient concn. of Cl in distd. water was present to destroy *Escherichia coli* and *Streptococcus fecalis*, cysts of the ameba were also killed. Practical aspects of these lab. results are pointed out. C. R. Fellers

Anaerobic technique; a modified deep agar shake. Norman J. Miller, Orville W. Garrett and Paul S. Prickett. *Food Research* 4, 447–51(1939).—Specially designed oval glass tubes are used for the nutrient agar. After solidification of the agar and inoculation of the tubes, the latter are filled about ⅔ full with reduced methylene blue agar contg. 1:20,000 parts of dye and 2% dextrose at pH 8.2 in order to det. the rate and depth of O_2 absorption. The depth to which O_2 penetrated into the medium never exceeded 15 mm. C. R. Fellers

Improved technique for isolating typhoid bacilli. Charles R. Tyler and Carolyn Oldenbusch. *Quart. Bull., City N. Y. Dept. Health* 6, No. 1, 12–16(1938); *U. S. Pub. Health Eng. Abstracts* 18, PHA, 22(Nov. 5, 1938).—The conclusion is reached after examg. 2800 specimens using Brilliant-Green agar media, Endo media, and a slightly modified Hajna Bi-sulfite media, that the greatest no. of positives were obtained in 48 hrs. by the last-named media.

It is recommended that both surface-inoculated and poured plates be used for the isolation of colonies. C. R. Fellers

Simple media for distinguishing the three types of Corynebacterium diphtheriae. Maurice Welsch and J. Thibaut. *Compt. rend. soc. biol.* **132**, 319-22(1939).—The use of K tellurite in media is discussed. **Morphological and biochemical properties of human Corynebacteria.** *Ibid.* 322-6.—The fermentation of different sugars by various strains is discussed. **Value of agar medium containing potassium tellurite and extract of blood clot for the bacteriological diagnosis of diphtheria.** Maurice Welsch, G. Demelenne-Jaminon and J. Thibaut. *Ibid.* 326-9. L. E. Gilson

Effect of temperature on bacteriostatic action of sulfanilamide on members of the Enterococcus group. Erwin Neter. *Proc. Soc. Exptl. Biol. Med.* **43**, 52-5 (1940); cf. *C. A.* **34**, 1047[9].—A 1% concn. of sulfanilamide in the culture medium retarded growth somewhat at 37° but usually completely checked growth at 43° without killing the organisms. L. E. Gilson

Action of sulfanilamide in vitro on aerobic sporogenic bacilli. L. Rosenthal. *Proc. Soc. Exptl. Biol. Med.* **43**, 78-80(1940).—Sulfanilamide, 1:1000 in the nutrient media, inhibits spore formation and induces degenerative changes in the bacilli of the subtilis-mesentericus-mycoides group. L. E. Gilson

Bacteriostatic actions of three thiazole derivatives of sulfanilamide on bacteria in broth cultures. C. A. Lawrence. *Proc. Soc. Exptl. Biol. Med.* **43**, 92-7(1940).—2-Sulfanilamido-4-phenylthiazole (sulfaphenylthiazole), 2-sulfanilamido-4-methylthiazole (sulfamethylthiazole) and 2-sulfanilamidothiazole (sulfathiazole) were much superior to sulfanilamide and sulfapyridine in their inhibitory actions on pneumococci types I, II and III and β-hemolytic streptococcus A. Concns. as low as 5 mg. % were bacteriostatic. Concns. of 1 mg. % were bacteriostatic for gonococcus. The first 2 were also markedly bacteriostatic for *Staphylococcus aureus*. L. E. Gilson

[Stimulating] effects of culture filtrates and old medium on growth of the ciliate, Colpidium campylum. R. P. Hall and J. B. Loefer. *Proc. Soc. Exptl. Biol. Med.* **43**, 128-33(1940); cf. *C. A.* **33**, 9350[9]. L. E. Gilson

Carbohydrate metabolism of Oidium lactis and Bacillus subtilis in a complex carbohydrate-rich medium. Theodore E. Friedemann. *Proc. Soc. Exptl. Biol. Med.* **43**, 148-51(1940); cf. *C. A.* **33**, 9354[2].—Both organisms produced about 70% of lactic acid on the basis of glucose consumed. About 20% of the C_3 intermediates from the sugar was further metabolized into 2 mols. of HCO_2H and 1 mol. each of EtOH and AcOH. No succinic acid was produced. L. E. Gilson

Pantothenic acid and nicotinic acid as essential growth substances for Morgan's bacillus, Proteus morganii. Michael J. Pelczar, Jr., and J. R. Porter. *Proc. Soc. Exptl. Biol. Med.* **43**, 151-4(1940).—Both compds. are necessary for growth of the organism. L. E. Gilson

Urea-treated virus as a vaccine against rabies. Anson Hoyt and Douglas Warner. *Proc. Soc. Exptl. Biol. Med.* **43**, 154-6(1940).—Rabies virus fixed in rabbit brain maintained its antigenicity and sometimes its infectivity in the presence of concns. of urea sufficient to liquefy most of the brain tissue. L. E. Gilson

In vitro conversion of prontosil soluble to sulfanilamide by various types of organisms. Wesley W. Spink, Frank W. Hurd and Jean Jermsta. *Proc. Soc. Exptl. Biol. Med.* **43**, 172-5(1940).—Different species of bacteria, and different strains of the same species, differed greatly in their ability to decolorize prontosil soluble. It was less easily decolorized than methylene blue under the same conditions. Sulfanilamide was one of the products formed. L. E. Gilson

Toxicity of basic fuchsin for certain bacteria. Cassandra Ritter. *Am. J. Pub. Health* **30**, 59-65(1940).—The dyes tested against 10 strains of bacteria which might be found in water are the homologs Pararosaniline or Magenta O, Rosaniline or Magenta I, Magenta II, new fuchsin or Magenta III, and 2 com. dyes—Pararosaniline and Rosaniline. The results for all organisms bear a relative titer corresponding to the no. of CH_3 groups in the dye radical, the bacteriostatic titer increasing with the larger no. of CH_3 groups. The 2 com. dyes showed bacteriostatic titers only slightly higher than those of the pure salts of which they are largely composed. This suggests the presence in these dye batches of small amts. of the higher homologs. The results of tests of a series of com. samples of basic fuchsin, composed of both acetate and chloride salts, suggest that the anion has small part in detg. the bacteriostatic titer. Basic fuchsin is used in fuchsin lactose broth for water analysis in a concn. of 0.0015%. This concn. of Pararosaniline or of Rosaniline would eliminate unwanted spore bearers but would not inhibit the coliform group, according to the expt. here reported. Either Pararosaniline or Rosaniline dyes can be used in fuchsin lactose broth where bacteriostatic action is desired. The former are preferable as the other homologs at times exhibit an erratic inhibitory effect on the *Escherichia coli* members of the coliform group. Magenta II and III are not suitable. All samples of basic fuchsin submitted for certification up to this time have been found satisfactory in accordance with the results of these expts. New batches of the dye can be tested by detg. the bacteriostatic titer, in comparison with the titer of the standard dye, for one coliform group organism and one aerobic spore-forming organism. Nine references. J. A. Kennedy

A biochemical study of the fermentation of rare sugars by members of the colon and aerogenes groups of bacteria. III. *d*-Fucose. J. Thomas Field and Charles F. Poe. *J. Biol. Chem.* **132**, 473-6(1940); cf. *C. A.* **29**, 4403[8].—Some 42 organisms of the *Escherichia* and *Aerobacter* groups of bacteria were used in detg. gas formation in media contg. fucose. Gas production took place very slowly and in 96 hrs. the colon cultures averaged 8% and the *aerogenes* cultures 11% of gas. The pH values with both groups of organisms in media contg. 0.1% of fucose reached a min. in about 7 hrs. (5 to 5.25) and then gradually increased to a max. of about 8.7. The min. was considerably lower (4.6) with 0.5 and 1.0% of fucose, and the acidity which developed killed the organisms in about 30 hrs. After 72 hrs., incubation the *aerogenes* group produced on the av. about twice as much lactic acid and 4 times as much succinic acid as the colon group and the ratio for the volatile to nonvolatile acids and for the acetic to succinic acid were more than twice as large as for the colon group. All members of the *aerogenes* group also formed acetylmethylcarbinol. The colon group produced more gases and alc. A. P. Lothrop

Fractionation of the bactericidal agent from cultures of a soil bacillus. Rollin D. Hotchkiss and René Dubos. *J. Biol. Chem.* **132**, 791-2(1940); cf. *C. A.* **33**, 8678[7].—Three cryst. substances have been isolated from cultures of a spore-bearing soil bacillus which are highly bactericidal for Gram-pos. microorganisms. Two acid substances are isolated by soln. of the crude material in alc., pptn. with 15 vols. of Et_2O and fractional crystn. of the dried ppt. from hot abs. alc. The one least sol. has been designated *graminic acid*, m. 232-4° (uncor.), $[\alpha]_D^{25}$ 115°. The more sol. is called *gramidinic acid*, m. about 230°, $[\alpha]_D^{25}$ −100°. The substance which remains sol. in the alc.-Et_2O mixt. but which is insol. in abs. Et_2O and crystallizes from Me_2CO is named *gramicidin*, m. 228-30°, $[\alpha]_D^{25}$ 5°. An actively growing type I pneumococcus is sterilized within 1 hr. by addn. of 10 γ of the acids or by 5 γ of gramicidin. Even 1 γ of this latter substance injected intraperitoneally will protect a large percentage of mice infected intraperitoneally with 10,000 fatal doses of virulent pneumococci. Gram-neg. organisms are unaffected either *in vitro* or *in vivo*. Gramicidin is highly toxic and 0.3 mg. will kill mice when given intraperitoneally. The nonprotective graminic and gramidinic acids are considerably less toxic. **Chemical properties of bactericidal substances isolated from cultures of a soil bacillus.** *Ibid.* 793-4.—Gramicidin has a mol. wt. of approx. 1400 and may be represented by the provisional formula, $C_{74}H_{108}N_{14}O_{14}$. It contains neither free basic nor acidic groups and is apparently a polypeptide contg. 10

mols. of α-amino acids of which 2 or 3 are tryptophan residues, these and a 14-16-C satd. aliphatic acid accounting for about 85–90% of the wt. of the substance. Gramicidin contains neither —OMe nor AcO— groups and histidine, arginine, tyrosine and NH_3 have not been found in the hydrolyzate. Graminic and gramidinic acids are similarly built up from amino acids but contain 1 free CO_2H group per mol. and apparently only 1 tryptophan group. Both contain tyrosine also. Graminic acid has a mol. wt. of approx. 900 ($C_{44}H_{63}N_9O_{11}$) and gramidinic acid of 1000 but reliable analyses have not yet been obtained on this compd. On acid hydrolysis gramicidin and gramidinic acid yield nearly 1/2 of their amino acids in the form of *d*- (the so-called unnatural) amino acids and this may possibly have some significance in their biol. activity.
A. P. Lothrop

Growth substances in agar. Wm. J. Robbins. *Am. J. Botany* **26**, 772–8(1939).—Spore formation, growth and the formation of gametes and zygotes by *Phycomyces blakesleeanus* were benefited by Difco agar. The beneficial materials could be partially extd. with MeOH, more completely with 5% aq. pyridine and are believed to be unknown growth substances. The development of *Phycomyces* was similarly benefited by potato, brown sugar, oatmeal and corn meal in the presence of thiamine; this indicates that these materials contain the same unknown growth substances. The presence of such substances is a factor to be considered in expts. with agar cultures. Nelson McKaig, Jr.

An improved method for the detection of bacterial urease. Justina H. Hill and E. C. White. *J. Bact.* **39**, 6(1940).—Organisms grown on a solid medium are washed free from NH_4 salts, suspended in a buffered urea soln. and incubated for 24 hrs. The suspension is satd. with NH_3-free Na_2CO_3. Any NH_3 produced by ureolysis is detected by its action of a small piece of indicator paper suspended above the emulsion. John T. Myers

A quantitative method for testing the bactericidal efficiency of volatile compounds. Milton J. Foter and Earnest R. Kline. *J. Bact.* **39**, 6–7(1940).—A standard amt. of the test organism is streaked on an agar plate and placed in a vacuum jar. Definite amts. of air were removed with an open-end manometer and replaced with air satd. with allyl isothiocyanate. Thus exact air and vapor mixts. could be prepd. John T. Myers

A clear liquid medium for the "aerobic" cultivation of anaerobes. John H. Brewer, *J. Bact.* **39**, 10(1940).—The base of the medium is glucose infusion broth, contg. 0.05% of agar. To this is added 0.1% of Na thioglycollate to insure the proper oxidation-reduction potential.
John T. Myers

The rough colony phase of Chromobacterium violaceum. W. G. Hutchinson. *J. Bact.* **39**, 13–14(1940).—Repeated cultures in broth contg. 0.5% LiCl produced rough forms. They differed biochemically only in fermenting glucose much more slowly. John T. Myers

The effect of certain cultural procedures on the rate of lactose utilization by slow lactose-fermenting bacteria. J. O. Mundt and E. R. Hitchner. *J. Bact.* **39**, 14(1940).
John T. Myers

The inhibiting effect of acetic acid with sodium chloride and sucrose on microörganisms. A. S. Levine and C. R. Fellers. *J. Bact.* **39**, 17(1940).—At equiv. pH values, greater toxicity was observed in those tubes contg. the greater amt. of acid. The toxic effect of acetic acid was only slightly enhanced by the presence of 5% NaCl and 20% sucrose. John T. Myers

Gradient of E_H and its significance in bacteriological media and body tissues. John W. Williams. *J. Bact.* **39**, 19(1940).—Since skin has more oxidized tissue than muscle, hydrolyzates of skin, muscle and hair are indicated for the growth of pathogenic fungi. Growth of fungi on hair is subsurface, on skin intermediate and on muscle superficial. John T. Myers

The incorporation of radioactive phosphorus in the nucleoprotein and phospholipide of Escherichia coli. Clara H. Williams, Leslie A. Sandholzer and Stanley N. Van Voorhis. *J. Bact.* **39**, 19–20(1940).—Radioactive P in the culture medium was incorporated in the nucleoprotein and phospholipide fractions. The ratio of radioactive P to total P was const. in each fraction and in the medium. John T. Myers

The inactivity of colchicine for bacteria. Marshall W. Jennison. *J. Bact.* **39**, 20–1(1940). John T. Myers

The relation of hydrogen-ion concentration to pigmentation of Actinomycetes. Jean E. Conn and H. J. Conn. *J. Bact.* **39**, 21(1940); cf. *C. A.* **34**, 1049⁸.—Some species produce pigments which are virtually H-ion indicators and the color observed in the medium varies with the final H-ion concn. The color can be changed by varying the amt. of glucose in the medium, thus changing the amt. of acid produced. John T. Myers

The production of hydrogen peroxide by type 3 strains of group A β-hemolytic streptococci. Faith P. Hadley and Philip Hadley. *J. Bact.* **39**, 21–2; *Proc. Soc. Exptl. Biol. Med.* **43**, 102–4(1940).—The amt. of peroxide produced may vary with different strains, with different colonies of the same strain and even with different parts of the same colony. John T. Myers

Studies in vitro on the stability of ascorbic acid toward intestinal microörganisms. Raymond M. Young and L. H. James. *J. Bact.* **39**, 23–4(1940).—Stock cultures of *Es. coli* and *A. aerogenes* oxidized ascorbic acid within 15 to 24 hrs. under both aerobic and anaerobic conditions. Sugars spared the oxidation of ascorbic acid. *Proteus*, *Alcaligenes* and *Lactobacillus* strains showed varying degrees of protection of ascorbic acid against atm. oxidation.
John T. Myers

The demonstration of phosphatase in Neisseria. Harold W. Leahy, Herbert E. Stokinger and Charles M. Carpenter. *J. Bact.* **39**, 24(1940).—*Neisseria* were grown for 6 days in ascites fluid-veal broth, centrifuged, washed in saline, lyophilized and stored at 5°. Phosphatase was present in the cells but in none of the supernatant liquids.
John T. Myers

The present status and problems of bacterial chemotherapy. E. K. Marshall, Jr. *J. Bact.* **39**, 25–6(1940); cf. *C. A.* **33**, 8821⁴. John T. Myers

The effect of sulfanilamide on the growth of Escherichia coli in certain synthetic media. R. H. Broh-Kahn. *J. Bact.* **39**, 26(1940).—Sulfanilamide may be bacteriostatic in the absence of mol. O. No correlation was discovered between its action and the accumulation of H_2O_2. It blocks enzymic reactions catalyzed by *Es. coli*, thus preventing the accumulation of foodstuffs either essential or beneficial to the growth of bacteria. John T. Myers

The biological significance of morphological changes in the pneumococcus induced by sulfapyridine. Ralph R. Mellon and Ruth A. McKinney. *J. Bact.* **39**, 26–7 (1940); cf. *C. A.* **34**, 1347⁴.—The variational effects of the drug on the pneumococcus *in vivo* may be viewed as the biol. counterpart of the action of H_2O_2 *in vitro*.
J. T. Myers

The mode of action of sulfanilamide. The effect of varying the medium upon bacteriostasis. Eleanor A. Bliss. *J. Bact.* **39**, 27(1940).—A strain of Lancefield A streptococcus is less susceptible to the drug in beef infusion broth contg. neopeptone than in broth contg. proteose peptone. A group G strain was very susceptible in broth contg. 25 of neopeptone but not affected in peptone glucose water contg. 0.7% each of neopeptone, proteose peptone and Pfansteil peptone. The nutritive value of the medium was not entirely responsible for these differences.
John T. Myers

The action of sulfanilamide in vitro on various species of Lactobacillus and Propionibacterium. Keith H. Lewis and Joseph E. Snyder. *J. Bact.* **39**, 28–9(1940).—Lactobacilli usually grew well in broth contg. 0.5% of sulfanilamide while *Propionibacterium* failed to grow. However, a no. of factors including amt. of inoculum and compn. of medium may cause wide variations in the results.
John T. Myers

The effectiveness of sulfanilamide in vitro and in vivo toward anaerobic hemolytic streptococci. E. H. Spaulding and Amedeo Bondi, Jr. *J. Bact.* **39**, 29–30(1940).—Permanently anaerobic hemolytic streptococci of Lance-

field's group A may be resistant to sulfanilamide in mice, but this resistance is not manifest in studies *in vitro*. John T. Myers

The nucleic acid-pneumococcal horse serum reaction. D. B. Lackman, M. G. Sevag and S. Mudd. *J. Bact.* **39**, 32–3(1940).—Nucleic acids from streptococci, pneumococci, bull spermatozoa, yeast cells, tobacco mosaic virus and thymus gland give a ppt. with serums from horses injected with pneumococci over a period of 3–5 yrs. The reaction is due to the nonspecific combination of some part of the globulin in hyperimmune pneumococcal horse serums with nucleic acid to form an insol. salt at pH values higher than those at which the proteins in normal and immune serums form insol. salts with nucleic acid. John T. Myers

Some chemical properties of normal serum globulins. Forrest E. Kendall. *J. Bact.* **39**, 34(1940).—The globulin fraction of normal human serum contains at least 5 serologically different proteins. Some have been isolated in a sufficiently pure form to permit study of their chem. properties. One of them reacts with other proteins and with certain bacterial proteins to give compds. insol. in water, but sol. in dil. salt solns., but the reaction is not specific. John T. Myers

Immunochemistry of the type-specific substance of meningococcus type II. A. E. O. Menzel and Geoffrey Rake. *J. Bact.* **39**, 34(1940).—The type-specific substance of type II meningococcus (Kappa) corresponding to the protective antibody is closely connected with certain protein fractions. It constitutes a prosthetic group firmly attached to meningococcal protein. J. T. M.

The anaphylactogenic property of Salmonella pullorum agglutinins. J. C. Foster, M. Scherago and R. H. Weaver. *J. Bact.* **39**, 35(1940).—Agglutinins for *S. pullorum* in immune rabbit serum are capable of sensitizing guinea pigs; hence they are antigenic. John T. Myers

Anti-egg albumin horse antibody. Alwin M. Pappenheimer, Jr. *J. Bact.* **39**, 36–7(1940).—The flocculation reaction between egg albumin and anti-egg albumin horse serum is analogous in almost every respect to the Ramon diphtheria toxin-antitoxin reaction. The antibody is concd. in the water-sol. pseudoglobulin fraction of the immune serum. There is evidence that the mol. compn. of the specific floccules is the same. John T. Myers

Inhibition of antibodies by degraded soluble antigens of vaccinia. Joseph E. Smadel and Thomas M. Rivers. *J. Bact.* **39**, 39–40(1940).—The heat-labile and heat-stable antigens of vaccinia can be degraded so that they no longer ppt. with sp. antibodies but still inhibit them. John T. Myers

The reaction of measles virus to ether. Geoffrey Rake and Morris F. Shaffer. *J. Bact.* **39**, 40(1940).—The agent of measles resists treatment with ether. J. T. M.

Studies on the effects in vitro of new sulfanilamide derivatives upon microörganisms. Carl A. Lawrence. *J. Bact.* **39**, 46(1940).—Thiazole derivs. are superior to sulfanilamide and sulfapyridine. John T. Myers

The development of sulfapyridine-fast strains of the gonococcus. Louise Westphal, Ruth L. Charles and Charles M. Carpenter. *J. Bact.* **39**, 47(1940). John T. Myers

Influence of carotenoids on the growth and acid resistance of the paratubercle bacillus. E. Darzino. *Ann. inst. Pasteur* **63**, 455-61(1939).—Carotene added to the glycerol gelatin media produces greater acid resistance in bacteria than a culture on gelatin without carotene. The increase in the no. of bacteria in carotene dets. the increase of their acid resistance and the progressive disappearance of their pigments involves the attenuation of their acid resistance. This increase in acid resistance is due to the elevation of the melting point of their fatty material. This increase confers on these bacilli a greater resistance toward heat, acids and dil. alkalies. The carotene is not essential for the life of these acid-resistant bacilli. Benjamin Prescott

Distribution of nitrogen and nitrogen metabolism in tetanus toxin. A. R. Prévot and H. J. Boorsma. *Ann. inst. Pasteur* **63**, 600–10(1939).—Tetanus toxin is dependent on a state of equil. of the nitrogenous constituents of the culture media, a ratio expressing the stage of the digestion of polypeptides. The titer of the toxin is a function of the ratio of polypeptide carboxyl to total carboxyl. This ratio is not the only factor inherent in the culture media which acts on the toxin. The normal content of vitamins in the media is very important. Deficiencies in these factors can be corrected by adding org. exts. or synthetic vitamins B_1,B_2 and P-P. Benjamin Prescott

Mandelic acid as a urinary disinfectant. R. von Werz. *Münch. med. Wochschr.* **86**, 1080–3(1939).—See *C. A.* **33**, 6961[5]. Maurice M. Rath

The specific nutritive requirements of Clostridium acetobutylicum (Weizmann). II. Ch. Weizmann and Bruno Rosenfeld. *Biochem. J.* **33**, 1376–89(1939); cf. *C. A.* **31**, 5505[3].—This organism belongs to those heterotrophic bacteria whose synthetic power is very restricted; it cannot synthesize the factors required for growth. Even in the presence of asparagine, combinations of aneurin, nicotinic acid and β-alanine, or uracil cannot replace the growth factors present in maize or yeast. Biotin is one of the active growth factors required. In order to bring the nutritive level of a synthetic medium up to 70% of the nutritional level represented by a maize mash both asparagine and biotin must be present. The missing 30% of the full requirements is due to a "third factor" which is present in the first dialyzates of autolyzed yeast. E. W. Scott

The biochemistry of microörganisms. LXIII. Itaconic acid, a metabolic product of a strain of Aspergillus terreus Thom. Christopher T. Calam, Albert E. Oxford and Harold Raistrick. *Biochem. J.* **33**, 1488–95(1939); cf. *C. A.* **33**, 9358[9].—Itaconic acid was isolated as a metabolic product of a strain of *Aspergillus terreus* Thom, isolated from American cotton yarn and positively identified as this mold, when it was grown on Czapek-Dox 5% glucose soln. The results obtained did not support the view that, with this mold, citric acid is an intermediate stage in the formation of itaconic acid from glucose. Five other strains of this mold produced no itaconic acid; 3 gave succinic acid, one formed fumaric acid and one gave oxalic acid. E. W. Scott

The production and utilization of lactic acid by certain propionic acid bacteria. Allen S. Phelps, Marvin J. Johnson and Wm. H. Peterson. *Biochem. J.* **33**, 1606–10(1939); cf. *C. A.* **33**, 2166[9].—*P. pentosaceum* produced only *l* (+) lactic acid (I) from glucose and arabinose and *P. technicum* only I from glucose. These 2 organisms and *P. shermanii* failed to racemize optically active lactic acid. The growth rates on the optical isomers of lactic acid varied in the order $d(-) < l(+) < dl$. The ultimate level of growth was the same in each case. The presence of both $d(-)$ and $l(+)$ lactic dehydrogenases in these organisms was shown. The latter had the greater activity. E. W. Scott

Antigenic property of monocytogenetic substance in blood. Itio Sato. *J. Chosen Med. Assoc.* **29**, 2326–70 (German abstr. 146–7)(1939).—The stimulation of the reticulo-endothelial system by India ink causes appearance of a large amt. of monocytogenetic substance in blood. This substance is a saponifiable lipide and possesses antigenic power. S. Tashiro

Antigen specificity of various pure proteins and their digestive products. M. Hasimoto and S. Kitamura. *J. Oriental Med.* **31**, 721–39(German abstr., 49)(1939). S. Tashiro

Soluble antigen of lymphocytic choriomeningitis. II. Characteristics of the antigen and its use in precipitin reactions. J. E. Smadel, M. J. Wall and R. D. Baird. *J. Exptl. Med.* **71**, 43–53(1940); cf. *C. A.* **33**, 6950[6].—The sol. antigen of lymphocytic choriomeningitis which is readily separable from the virus is a relatively stable substance and appears to be of a protein nature. A specific precipitin reaction can be demonstrated when immune serum is added to solns. of antigen which have been freed by certain serologically inactive substances. C. J. West

Protein fractions of a strain of group A hemolytic streptococci. III. Michael Heidelberger and Henry W. Scherp. *J. Immunol.* **37**, 563–70(1939).—Further studies

(*C. A.* **25**, 5909) are reported of the protein fractions of a strain of hemolytic streptococci of group A, which furnish new evidence that much of the nucleic acid present in a neutral-extractable nucleoprotein is bound more firmly than in dissociable salt linkage. This nucleoprotein and the proteins derived from it by alk. degradation have similar serological properties. Charles A. Zittle

Antonie van Leeuwenhoek Journal of Microbiology and Serology (*New journal*). Published quarterly by the Nederlandsche Vereeniging voor Microbiology. T. Folpmers, Secy., 245 Honingerdijk, Rotterdam-O., Holland. Subscriptions should be sent to N. V. Swets & Zeitlinger, 471 Keizersgracht, Amsterdam, Holland. Vol. 1, No. 1 appeared in 1934 but an English edition began with Vol. 6, No. 1 (Jan. 1940). Fl 10.60 per yr.

THOMAS G. PHILLIPS

Applicability of the preheating treatment in the extraction of tissue fluid from cotton leaves. Noboru Yamada. *J. Coll. Agr., Tokyo Imp. Univ.* **14**, 417–28(1939).—Comparisons were made of the vol., the osmotic value and the pH value of the sap obtained by the preheating and prefreezing methods of treating cotton leaves prior to sap extn. In some cases the osmotic value of the sap expressed from heated samples was slightly higher than that from frozen samples, which difference, however, is practically negligible. The amt. of sap obtained by either of these treatments is apparently the same. It is notable that the heat method alters the pH value of the tissue fluid during treatment, while with the freezing method the sap shows a pH value similar to that expressed from untreated leaves. The most suitable length of time for heating was found to be from 15 to 30 min. The heat method is quite reliable in studying the osmotic value of the tissue fluid from cotton leaves, causing no serious changes in the osmotic concn. of cell sap. This method, moreover, is simple, time-saving, economical and suitable for extended collections, its only drawback being that it is inapplicable in studying the H-ion concn. of the sap. 27 references. Edward A. Ackermann

The chemotaxis of algae gametes. Franz Moewus. *Arch. Protistenk.* **92**, 485–526(1939); cf. *C. A.* **32**, 8457[2]; **33**, 4030[4,8]; **34**, 469[7].—Under aerobic conditions the sugars (1% solns.) most favorable for motility are gentiobiose for *Chlamydomonas eugametos* (I), cellobiose for *Chl. dresdensis* (II) and cellotriose for *Chl. braunii* (III); *l*-arabinose, *d*-ribose, *d*-xylose, *d*-mannose, *d*-galactose, *d*-fructose and *l*-sorbose have no effect. I formed and excreted crocin, while the other species formed and excreted motility substances probably related to crocin but not to derivs. of *cis*- and *trans*-crocetin esterified with gentiobiose. The no. of crocin mols. required to make a cell of I, II or III motile are 1, 10^6 and 10^6, resp. Crocin dark cells (IV), young gametes (V) and reactive gametes (VI) are chemotactic toward sugars which affect the motility. The sugar with the lowest stimulation threshold is also the one with the most favorable action on the motility. The stimulation threshold of the most favorable sugar is $M/10^4$ for all 3 species. With I, II and III the crocin solns. which act as chemotactic agents must be 10^4, 10^5 and 10^6 times more concd., resp., than the crocin solns. in which the cells occur. IV, V and VI behave differently toward *cis*- and *trans*-crocetin di-Me ester. IV in a soln. contg. neither *cis*- nor *trans*-crocetin di-Me ester are chemotactic toward all cis/trans mixts. of 100/0 to 0/100. V, in a concd. aq. soln. of *cis*-crocetin di-Me ester, do not become chemotactic until the mixt. contains 80 parts by vol. of the cis and 20 parts by vol. of the trans ester; they are not chemotactic toward cis/trans mixts. of 100/0 to 85/15. VI, in a definite cis/trans mixt., are chemotactic toward cis/trans mixts., if the difference between the solns. amounts to at least 19/19; they are not chemotactic at differences of 0/0 to 18/18. VI are also chemotactic toward natural gamete filtrates; here the cis/trans difference must be at least 20/20; at differences of 0/0 and 10/10 no chemotactic attraction results. The seeking of gametes for copulation is a chemotactic process, in which only the sex substances act as chemotactic agents. All phenomena of chemotaxis, as well as the speed of the chemotactic reaction, agree wholly with the phenomena of group formation and the ideas developed from the theory of the relative sexuality. Ruth Berggren

The size of the tobacco mosaic particle from x-ray determinations. John W. Gowen. *Proc. Natl. Acad. Sci. U. S.* **26**, 8–10(1940); cf. *C. A.* **31**, 3959[1], 7073[6].—Ordinary tobacco mosaic and several of its derivs. were irradiated with x-rays from Cr, Cu and Ag, the effective wave lengths being 2.1, 1.5 and 0.7 A. The survival curves show that the inactivation rates of tobacco mosaic and its derivs. are essentially alike. The av. size of the vital vol. of the mosaic particle is 7.5×10^{-18} cc. The mol. wt. of the tobacco mosaic virus, confirmed by x-ray expts., is 16–20 million. The large portion of this mol. is important to its reproduction, a smaller portion being capable of change without affecting this power to reproduce. The virus entity may be a repeat mol. with a mol. wt. of 40–100 million; this conclusion gives added significance to the relative strengths of the bonds between the different mol. elements. Ruth Berggren

The nature of absorption of radioactive isotopes by living tissues as illustrated by experiments with barley plants. R. Overstreet and T. C. Broyer. *Proc. Natl. Acad. Sci. U. S.* **26**, 16–24(1940); cf. *C. A.* **32**, 9177[1]; **33**, 9516[7].—Equil. studies indicate that plant roots may absorb radioactive ions by simple exchange of radioactive isotopes of the surrounding culture medium for nonradioactive isotopes initially present within the plant. Barley plants with low K levels absorb radioactive and nonradioactive isotopes of K in nearly const. proportions from dil. KCl solns. in which the radioactivity of the dry salt is of the order of 1 microcurie/l. Under similar conditions barley plants with moderately high K levels favor the radioactive isotopes in absorption. Under the exptl. conditions, plants with high K levels or plants maintained at low temps. do not show a net absorption of K but do absorb radioactive K, indicating a process of exchange of radioactive isotopes in the culture medium for nonradioactive isotopes in the roots. The fraction of K in the root capable of rapid exchange for isotopes in the culture medium has been calcd. and is believed to be assocd. with the colloidal phases of the protoplasm and the cell wall; it may have a special significance for the study of certain aspects of the ionic interrelations of the root and culture medium. Ruth Berggren

Adsorption of metallic colloids on protein bodies. I. The reaction of colloidal gold-tobacco mosaic virus. G. A. Kausche and H. Ruska. *Kolloid-Z.* **89**, 21–6(1939).—The addn. of colloidal gold to tobacco mosaic virus led to the formation of a red flaky ppt. upon acidification (as viewed under the ultramicroscope). In this it differed from the X-potato virus which forms the ppt. even in neutral solns. This red ppt. is considered to be the result of adsorption of gold-sol particles on the tobacco mosaic virus protein mols. Addn. of NaCl to neutral solns. of gold sol and tobacco mosaic virus protein led to a blue ppt., this being an aggregate of gold particles only without any interaction between the colloidal gold and the protein. Alkalinization dissolves the red gold sol-protein combination and denatures the protein. S. A. Corson

Chemical studies on the quality of inbred lines of sweet corn. J. T. Sullivan and J. R. Roach. *Purdue* (*Ind.*) *Agr. Expt. Sta., Rept. of the Director* **1937**, 9; cf. *C. A.* **33**, 8242[6].—Sol. polysaccharides were detd. on 18 inbred lines of sweet corn, stored at const. temp. and sampled periodically for analysis. The sol. polysaccharides at first increase during storage and then decrease. Starch decreases and then increases. In the 1st 25 hrs. of storage respiration accounts for more than $^1/_2$ of the loss in sugars, the range in the different samples being from 0.3 to 1.1% of the initial sugar content. During the next 50 hrs. of storage the amt. of sugar lost by respiration was usually

less than during the 1st period. At the end of 75 hrs. of storage the corn differed from its original condition by having less moisture, less sugar, less total carbohydrate and a greater proportion of the more complex and less sol. carbohydrates. The kernels have a greater water absorbing capacity. Golden Bantam No. 1409 showed the highest sugar content at all times except at harvest and the lowest rate of sugar loss during storage. Golden Standard had the highest initial sugar content but lost sugar more rapidly than any other variety. Its polysaccharide content was the lowest at all times. C. R. Fellers

The role of manganese in the assimilation of nitrate. Hans Burström. *Planta* **30**, 129–50(1939).—Continued (cf. *C. A.* **33**, 4628[4], 5444[8]) expts. with roots of wheat seedlings confirmed the assimilation of nitrate only in the presence of Mn. All other neutral salts tried hindered assimilation (conversion to protein), i. e., Li, Na, K, Mg, Ca, Sr and Ba, besides heavy metals, as sulfates, carbonates or phosphates. It was established that this effect depended solely upon the cation. The interference was such as to suggest that it was due to an exchange of cations. The expts. support the hypothesis that the Mn that effects the assimilation is adsorptively bound in the cell plasma and the other cations obstruct assimilation by displacing the Mn from this attachment. Mn participates in the reduction of both nitrate and nitrite. Support is found for the belief that a single oxidation reduction reaction accomplishes the whole reduction process of nitrates to (NH_3 or RNH_2). The interdependence of the basal respiration of the roots and the assimilation of nitrate is discussed thermodynamically, with the emphasis upon the fact that Mn catalyzes both processes. Twenty-two references. E. L. Green

The effect of β-indolylacetic acid upon the size of starch grains of potato (Solanum tuberosum). M. Zika. *Planta* **30**, 151–9(1939).—After treatment of the seed pieces with β-indolylacetic acid (I), the yield of tubers was considerably increased and the starch granules were larger than usual. Likewise a subsequent effect of the more vigorous development could be observed in the following vegetative period. Varieties differed in their sensitivity to added I. Even leaf cuttings demonstrated the effect of the concn. of I upon the size of the starch granules. Preliminary trials with other plants indicated a general application of this relationship. E. L. Green

The retardation of cell elongation by naturally occurring ether-soluble substances. Poul Larsen. *Planta* **30**, 160–7 (1939).—Three different ether-sol. growth-retarding substances were found in ripe tomatoes. Two of these were water-sol., and of these one might be identical with "blastokolin" and is acid; the other is neutral. In maize grains a growth-substance inhibitor sol. in ether and not acid was found. The existence of these substances was proved by the paste method of Laibach (cf. *C. A.* **28**, 3443[1]) and by their ability to retard growth initiated by a soln. of auxin. E. L. Green

The analysis of permeability measurements. Fr. Bachmann. *Planta* **30**, 224–51(1939).—The processes of the gain and loss of water during plasmolysis and deplasmolysis are regarded as diffusion phenomena more or less disturbed by turbulence. The velocity of inward and outward movement of water depends principally upon the velocity of diffusion of the materials dissolved in the interior plasma. If undisturbed diffusion takes place also in the wall or in the cell sap, then this applies to those regions and their solutes as well. Even if the water permeability of the total plasma is obviously high, with few exceptions the possibility still remains that in the boundary layers it is decidedly less. The permeability of the boundary layer may not vary if only the diffusion coeffs. of the solutes of the interior plasma and ratio of total plasma depth to boundary-layer depth fluctuate. E. L. G.

Discovery of inactive growth substance, of antigrowth substance, and of their significance in the regulation of growth. Hans Voss. *Planta* **30**, 252–85(1939).—Embryos of maize sepd. from endosperm and scutellum require the reserve growth substance of the grain for their normal and original development. Heteroauxin cannot replace the natural growth substance in the germination stage. In this case the 2 hormones for elongation have different effects. The scutellum of maize contains inactive growth substance which can be demonstrated by freshly decapitated oat coleoptiles. This inactive growth substance of the scutellum is sol. in alc., ether, chloroform, and water and is heat-stable, but in contrast with active growth substance it is not destroyed by treatment with perhydrol. The auxin of the endosperm migrates to the scutellum as a result of swelling, is inactivated there, and can then be transported acropetally into the embryo. A slower apical transport of active natural growth substance was shown for higher concns. The cells of the coleoptile store the inactive growth substance of the scutellum, and the apical cell activates a definite quantity in a unit time. This limited activating power of the apical cell is an important factor in the regulation of the extension of the coleoptile. The activation is affected by the quantity of active growth substance already present in the coleoptile; the age of the cells also has an effect. All the cells of the coleoptile can activate the growth substance of the scutellum up to a certain degree of differentiation. There must be a dominant polarity in the coleoptile that prevents all except the apical cell from constantly exercising this function. As the cells age, they lose not only their activating power but also their responsiveness to added growth substance. Both factors contribute to the limitation of the growth of the coleoptile. Especial importance for the regulation of the growth of the young maize seedling attaches to a substance that can be extd. from the endosperm and scutellum which is to be regarded as an antigrowth substance (Hemmstoff). This reduces the responsiveness of the cells to growth substance and thus retards the elongation of the mesocotyl and coleoptile, but promotes or initiates root growth. The Hemmstoff diffuses through the coleoptile without regard to polarity. Its effect follows a probability curve. It is probably formed under the influence of light. One hundred and twenty-seven references.
E. L. Green

Analysis of positive and negative phototropic bendings. Marga Wilden. *Planta* **30**, 286–8(1939).—The 2 sides of oat coleoptiles were tested upon decapitated coleoptiles (1) after dividing into illuminated and shaded halves, (2) by attaching the illuminated or shaded side of the undivided tip to the stump of another coleoptile. The results differ from those of Asana (*C. A.* **33**, 1781[6]). For both methods the ratio of growth substance on the illuminated side to that on the shaded side is less than 1 for pos. bendings and more than 1 for neg. E. L. Green

The importance of carotenoids in the utilization of light in photosynthesis. K. Mothes, I. Baatz and H. Sagromsky. *Planta* **30**, 289–93(1939).—Expts. on marine diatoms and brown algae are reported in which no direct effect of illumination upon respiration could be found. The utilization of various spectral regions was studied, and the type of response (mitosis, injury, respiration, photosynthesis, etc.) recorded. The refinements of technique have disclosed responses that remove support for certain concepts and make it appear that the living forms of the pigments absorb light differently from their exts.
E. L. Green

The influence of the neutral salts of alkali and alkaline earth metals on plant growth. Heinrich Borriss. *Ernähr. Pflanze* **35**, 289–97(1939).—A method of investigating the action of K, Na, Rb, Li and Ca ions on the growth of seedlings of *Spergula arvensis*, caryophyllaceous *Gypsophila elegans*, *Silene coeli-rosa*, *Agrostemma githago* and *Nicotiana rustica* is described which consists in placing the seedlings in contact with blotting paper, which is supported on a glass plate, and extending into the neutral salt soln. The salts used in 0.01 *M* solns. were all in the form of chlorides to eliminate the influence due to different anions. The temp. was maintained at 20°, light was excluded and the surrounding air was satd. with H_2O during the period of 160 hrs. required for measuring the rate of elongation of the hypocotyl. K produced best results in all cases and was followed closely by Na in *Spergula arvensis*. Rb caused a rapid rate of growth for the first 40 to 60 hrs.

The use of KNO_3 soln., as compared with either KCl soln. or distd. H_2O, greatly increased the K content of the hypocotyl and cotyledon of *Agrostemma githago*. Other methods of measuring the effect of nutrients on plant growth are discussed. John O. Hardesty

The chemical composition and possible effects of Carpobrotus edulis N. E. Br. Florence V. Stephen-Lewis. *S. African J. Med. Sci.* **4**, No. 1–2, 7–9(1939).—Water extd. 39.56%, and 90% alc. extd. 32.48%, of material from the dried leaves and stems. The ash from these was 26.4% and gave pos. reactions for K, Na and Ca. An ext. made with Prollius fluid was neg. to tests for alkaloids. The alc. ext. was dark red and gave a brownish red brittle residue on evapn. This was sol. in NaOH and a ppt. appeared on acidifying. The ppt. gave pos. reactions for phlobaphenes to Ware's formaldehyde test and the $FeCl_3$ test. A brownish decoction made by heating the dried material with water on a water bath gave a deposit on cooling. This dissolved on heating and on adding alc. It was acid in reaction and formed a heavy froth on shaking. Molisch's test for carbohydrates and tests for tannin with $FeCl_3$ and Fe alum were pos. A small portion of this ext. was evapd. to dryness and gave a crimson color with concd. H_2SO_4, an indication of the presence of saponin or of catechol tannins. No saponins were found by various methods of extn. The presence of tannin was confirmed by its complete pptn. by boiling the ext. with formaldehyde and HCl and by its pptn. with Br water. Hydrolysis of the ext. by boiling with 10% HCl gave a red ppt. and the filtrate on suitable treatment yielded a glucosazone, m. 202°. The ppt. gave a pos. Ware's reaction for phlobaphenes. The hide-powder method gave 8.052% of tannin. A portion of the decoction was treated with Pb acetate, the Pb ppt. treated with 50% alc. and ammonia according to Fleischer's method (*Arch. Pharm.* **205**, 97 (1874)). The final Pb-free filtrate showed the presence of malic and citric acids. Six references are given. W. R. Henn

The culture behavior of a species of Rosellinia. I. Inhibitory effect of certain chemicals on the production of perithecia. S. N. Das Gupta. *J. Indian Botan. Soc.* **16**, 359–70(1937).—In proportions given for the standard medium, glucose, asparagin, $MgSO_4$ and K_2PO_4 individually have no inhibitory effect. Asparagin and K_2PO_4 exert a strong inhibitory effect when used together. The effect is accentuated by the addn. of glucose and starch and lessened by the addn. of $MgSO_4$. Glucose completely inhibits the formation of perithecia at concns. of 0.4% and higher, but the growth rate of the fungus is not affected. K_2PO_4 inhibits the formation of perithecia at about 0.6% concn., an amt. considerably higher than that used in standard synthetic media. K. D. Jacob

March of transpiration of a leaf from its measurable stage to its fall. P. Parija and B. Samantarai. *J. Indian Botan. Soc.* **18**, 65 77(1939).—Expts. were carried out on attached leaves of *Helianthus annuus*, *Datura alba* and *Ixora undulata*. From the time the leaf is large enough for experimentation, the transpiration first increases and then falls to a steady value, after which it decreases. With evergreen leaves the steady phase of transpiration is much longer. The transpiration of the exptl. leaf is affected by the environmental humidity of the plant. K. D. J.

Synthetic growth substances. L. C. Chadwick and D. C. Kiplinger. *Trans. Iowa State Hort. Soc.* **73**, 171–5 (1938); *Proc. Am. Soc. Hort. Sci.* **36**, 809–16(1939); cf. *C. A.* **33**, 9362[7].—Softwood cuttings of 89 species of ornamental plants responded favorably to treatment for 24 hrs. with solns. of indolebutyric acid (0.5–2.0 mg./100 cc.). Only 1 plant, *Cornus florida rubra*, showed no rooting of untreated cuttings but good rooting when treated. In general, the rooting percentage between untreated and treated cuttings was not changed by the use of indolebutyric acid if the untreated cuttings were allowed to remain in the bench the normal length of time. By treating the cuttings, the time required to reach the normal rooting percentage was decreased. With plants that produce roots with a definite arrangement in regard to the node and position of cut, treatment with indolebutyric acid failed to change the relationship. Narrowleaf evergreens difficult to propagate by cuttings were not benefited by treatment. With softwood cuttings the quality of the root systems was greatly improved by treatment with growth substances. K. D. Jacob

The distribution of chemical substances in tobacco. II. Protein substances. I. D. Vladescu and N. Dimofte. *Bul. cultivarii fermentarii Tutunului* **28**, 330–43(in French, 343)(1939).—An examn. of the variation of the protein elements in tobacco leaves of different levels and within each leaf, the stem, the root, and the flower led to the following results. In percentage of dry substance the protein substance increases continuously from the first base to the last top leaf (358% for the Molovata variety, 182% for the Ghimpatzi variety). The protein substance increases in the stem from the base to the top (241%). The secondary roots are richer in protein than the main root; the flower is richest in protein elements. The quantity of protein substances in 100 leaves of various levels differs with their wt. and the protein percentage of the dry substance of these leaves. The distribution of the protein substance throughout the various plant organs varies with the development of the plant. At the time of flowering the following distribution was found in the Ghimpatzi variety: leaves 51%, stem 27%, flower 13%, root 9% of the protein content of the entire plant. Cf. *C. A.* **32**, 8472[4]. A. H. K.

Effects of alkali salts on germination of seeds. B. T. Mulwani and A. G. Pollard. *Agr. Live-stock India* **9**, 548–55(1939).—Seeds were germinated in 50 g. of soil or sand in Petri dishes to which varying concns. of NaCl were added. The smallest concns. of NaCl stimulated germination. When this was exceeded, the seeds were injured. The order of decreasing sensitivity of seeds to NaCl injury was corn, oats, wheat, barley, peas, sugar beet, red clover, mangold, mustard, lucerne and paddy. Delay in time of germination and injury to barley was in the following order of decreasing severity: Na_2CO_3, $MgCl_2$, NaCl, Na_2SO_4. The presence of 0.5% $CaSO_4$ decreased injury caused by Na_2CO_3 and $MgCl_2$. Nelson McKaig, Jr.

Respiration and fermentation in the carrot, Daucus carota. II. Fermentation and the Pasteur effect. Paul B. Marsh and David R. Goddard. *Am. J. Botany* **26**, 767–72(1939); cf. *C. A.* **34**, 469[1].—Respiration expts. with thin slices of carrot tissue produced a ratio of anaerobic to aerobic CO_2 of 1.15 indicating the existence of the Pasteur effect. No measurable amts. of org. acids were produced by respiration in N_2. Fermentation occurred and the R. Q. was increased from 0.8 to 3.3 when respiration was inhibited by O pressures of 5 to 1%, resp. By sepg. the respiration and fermentation mechanism through use of CO, CN^- and NaN_3, it was found that the results were not consistent with the Lipmann theory (*C. A.* **28**, 188[9]) of oxidation of a fermentation enzyme unless the oxidation is catalyzed by cytochrome oxidase. The results were consistent with, but did not prove, the Meyerhof (*C. A.* **20**, 1817) oxidative resynthesis theory. The Pasteur effect is not poisoned by Et isocyanide, KCN or low O pressure. NaN_3 and CO induce aerobic fermentation; the effect of the latter is reversed by light. Nelson McKaig, Jr.

Differential growth in plant tissues. II. A modified auxin test of high sensitivity. Kenneth V. Thimann and Charles L. Schneider. *Am. J. Botany* **26**, 792–7(1939); cf. *C. A.* **33**, 1009[7], 6908[3].—Concns. of indoleacetic acid as low as 0.01 γ per l. can be detected by the curvature of *Avena* coleoptiles slit into 4 parts longitudinally. This is 30 times the sensitivity of the usual *Avena* coleoptile test. The increased sensitivity of the test is caused by mech. factors affecting the curving sections. A *tool*, consisting of a brass holder with a slit 1.5 mm. wide to hold the coleoptile and a cutter which slides along the slit and cuts the coleoptile with an inserted piece of safety razor blade, is described. Nelson McKaig, Jr.

Factors influencing the efficiency of photosynthesis. Robert Emerson and Charlton M. Lewis. *Am. J. Botany* **26**, 808–22(1939); cf. Warburg and Negelein, *C. A.* **16**, 1316.—The efficiency of photosynthesis (I) in *Chlorella pyrenoidosa* depends on a no. of factors. Traces of heavy

metals usually present as impurities in the water or Fe salt used in the culture soln. and which were independently added as stock solns. of microelements (*C. A.* **32**, 7517[8]) increased the efficiency. A light intensity of about 900 lux followed by a reduction for a few days before harvesting appeared optimum. The age of the culture affects the efficiency by the amt. of growth and light absorption due to mat thickness and the exhaustion of nutrients from the medium, which are interdependent. The quantum yield depends upon the wave length of light used. Cultures grown at 10° were 7% less efficient than those grown at 20°. Optimal adjustment for one factor depends upon the other factors. Conditions during measurement of I were best at 10°, and under a light intensity of about 300 lux. Yields with Na light from a. c. sources were similar to those obtained from d. c. The efficiency of I depends on CO_2 concn. It was 25% lower at 0.5% and somewhat lower at 12% than at 5% CO_2 at 10° with 10 min. light and dark periods, with thick suspensions and low light intensities. Higher light intensity diminished the dependence of yield on CO_2 concn. By suitable control of the above factors, quantum yields of 0.33 were obtained with a probability that higher values could be obtained by further adjustment of conditions. Hence the earlier assumed max. of 4 light quanta per mol. of CO_2 is not correct, and either methods of measurement or the postulated chem. mechanism of I is in error. Manometric measurements of respiration were made at 30–60-sec. intervals with an improved cathetometer reading to 0.01 mm. Light and dark periods of less than 10 min. each did not reduce errors in respiration measurement because of large temporary deviations from the steady pressure values. Quantum yields are highly dependent upon the portion of the respiration curve measured, the incident illumination, the calibration of the bolometer and deviations of the CO_2/O_2 ratio (γ) from unity, possibly by formation of intermediate products. The exptl. technique is described in detail. Nelson McKaig, Jr.

Nature of growth differences in two sorghum varieties. I. Influences of preliminary soaking on early growth and auxin content. Robertson Pratt and Harry G. Albaum. *Am. J. Botany* **26**, 822–6(1939).—Standard Yellow Milo (I) and Dawn Kafir (II) seed were soaked in distd. water for different lengths of time, germinated on cork floats and the rate of root and shoot growth measured. The rate of shoot growth of I was decreased by increased time of soaking but the rate of root growth was increased for the first 24 hrs. of soaking and then decreased by longer immersion. II was unaffected by the treatment. Frequent changing of the water used for soaking increased the effect in the case of I. *Avena* tests showed I seed had 70–80% the auxin content of II, but after soaking I had 40–45% the auxin content of II. Nelson McKaig, Jr.

The effect of boron in the substrate on calcium accumulation by soybean plants. C. E. Minarik and J. W. Shive. *Am. J. Botany* **26**, 827–31(1939).—B was added at 14 concns. to soybeans grown in sand cultures with B-free nutrient solns. B injury occurred in 18 days at 10 p. p. m. and necrotic spots caused by Fe toxicity were caused by B at lower concns. B-deficiency symptoms occurred at B concns. of less than 0.025 p. p. m., plants receiving 0.025–1.0 p. p. m. were healthy, above 2.5 p. p. m. B toxicity occurred. Max. amts. of Ca calcd. on both the ash and tissue bases were found in leaves of plants receiving optimum B. No effect of B on total ash occurred. Except for the 2.5 p. p. m. concn. of B, the total leaf tissue produced was closely proportional to the percentage of Ca found in the leaves; this indicates that tissue production and Ca content were affected by B in the same way and to the same degree. The fact that increasing concns. of B decreased the moisture content of the leaves indicates that B exerts some control over the swelling of plasma colloids. Nelson McKaig, Jr.

Hydrogen-ion concentration of leaf juice in relation to environment and plant species. Annie M. Hurd-Karrer. *Am. J. Botany* **26**, 834–46(1939).—The acidity of the juice from normal wheat leaves during the vegetative period ranged from pH 5.85 to 6.38. pH decreased to about 5.5–5.3 during maturation. Unhealthy plants became prematurely acid, none having a pH lower than 5.3. Temps. above 20° and light periods of 17 hrs. increased the acidity; this explains the abnormal acidity of spring-sown winter wheat. Acidity was decreased by 8-hr. light periods, which favored vigorous growth. The effect of temp. on acidity was dependent upon the temp. injury. There was no difference in the pH of different wheat varieties, or of wheat grown on soil to which varying amts. of lime had been added. Juice acidities reported for 59 crop plants are reviewed, in addn. to 52 references. Nelson McKaig, Jr.

The effects of magnesium and calcium on "white-tip" of rice. Alan L. Martin. *Am. J. Botany* **26**, 846–52 (1939).—Growth of rice plants in soil and water cultures deficient in Mg caused leaf chlorosis (I) similar to the "white-tip" observed in the field. I was eliminated by addn. of 81 p. p. m. Mg to the soil cultures and 27 p. p. m. to the water cultures, but the addns. were toxic unless Ca was also supplied. Ca concns. of 9 p. p. m. or more in Mg-free cultures caused stunting and brown leaf spots which were not present when Mg was added. The greatest benefit from the antagonistic action of Mg and Ca occurred with Mg:Ca ratios of 1:1 or 1:3 when Ca and Mg were present in concns. of 27, 81 or 243 p. p. m. Nelson McKaig, Jr.

Chemical structure of substances inducing polyploidy in plants. A. A. Shmuk and A. Guseva. *Compt. rend. acad. sci. U. R. S. S.* **24**, 441–6(1939)(in English).—The polyploidogenic action of over 100 carbocyclic and heterocyclic compds. was detd. by evapn. of the Et_2O soln. contg. 1 mg. of substance on a filter paper in a Petri dish, moistening the paper with water and sprouting wheat seed. The action was related to the structure of the acenaphthene and naphthalene derivs. tested, and in agreement with the action of similar derivs. of other compds. The following α-derivs. of naphthalene (I) were active: Cl (II), Br (III), I (IV), COOEt (V), OCH_3 (VI), CN, NO_2 (VII) and CH_3; the following were inactive, β-Cl, β-Br, β-I, α- and β-SO_3H and salts, and α- and β-NH_2, α-COOH and salts, β-OCH_3, α- and β-OH, β-CN and β-CH_3. I was weakly active. Acenaphthene (VIII) and its 5-Cl (IX) and 5-Br (X) derivs. and acenaphthylene (XI) were active. The following 5-derivs. of VIII were inactive: I; SO_3H and salts; NH_2; OH; COOH and salts; NO_2; also the 1,2-di-Br; 1,2-di-OH (*cis* and *trans*); 5,6-di-NO_2 and x-tetrabromoacenaphthene. p-Dibromobenzene (XIII) was feebly active. The effects of II to XI, 3,5-dibromopyridine (XII) and XIII, were tested on different plants. Of these, all were effective in inducing polyploidy in wheat and barley, all but II and XIII in tobacco and *N. rustica* and all but II, III, VI, VIII, X and XIII in flax. Peas, vetch and clover responded only to V, VII and XII. Similarities between the compds. studied and those inducing carcinoma in animals are discussed. Nelson McKaig, Jr.

Mechanism of auxin-formation in green plants. L. P. Zhdanova. *Compt. rend. acad. sci. U. R. S. S.* **24**, 505–8 (1939)(in English).—The place of auxin formation in *Hydrangea hortensis* (I) was detd. by removing the growth points of 1 shoot, stripping leaves from a second and using a third shoot as control. A second plant was stripped of leaves. The shoot tips were tested for auxin 5 to 6 days later by Went's method (cf. *C. A.* **33**, 5887[6]). None was found in stems lacking growth points or plants from which all leaves were removed but it was present in the tips of leafless shoots. Apparently auxin is produced in growth points from substances stored by leaves and which can move freely in the plant. All buds were removed from *Vicia faba* (II) plants 1 month old and 7–9 days later auxin was extd. from the leaves with Et_2O. The auxin content was much lower than that in leaves of normal plants. Leaves cut from whole and decapitated I and *Helianthus tuberosus* were kept in light and darkness. Under both conditions, leaves from decapitated plants gave no geotropic response but the response of leaves from normal plants was marked, an indication that auxin is developed in the buds and flows down the stems to the leaves. Covering whole plants or only the leaves of tobacco (III) or

chrysanthemum (IV) with varying amts. of gauze to influence the incident light showed that a decrease in auxin in the tips was decreased to a similar extent by decreased illumination of either the whole plant or only the leaves. Vacuum infiltration of 0.2 and 0.4 mol. glucose daily into III and IV kept for 10–15 days in the dark caused auxin production which was absent in plants receiving no glucose. Introduction of 2% glucose into stems of leafless I produced auxin in the growing tips which was absent from controls receiving distd. water. Auxin-free tips 2.5 cm. long of II were grown on glucose soln. for 5–6 days and tested for auxin. Its presence proved that plant leaves did not synthesize or store auxin precursors. It is concluded that the mechanism of auxin formation includes photosynthesis of sugars in the leaf and their transport to the growing buds where they are converted to auxin. From the buds, auxin flows to the lower stems and leaves. Nelson McKaig, Jr.

Qualitative variations of rubber in the roots of kok-sagyz at the second year of vegetation. S. M. Mashtakov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 509–12 (1939) (in English); cf. *C. A.* **33**, 6645[3].—The 2nd year's development of kok-sagyz differs from the first in the development of a root sheath during the spring growth of the 2nd yr. and its destruction by soil microörganisms during and after the summer dormant period. The rubber content increases during the spring period. The percentage of rubber in the whole root increases but the total amt. is unchanged as the sheath disappears. The η and mol. wt. of the rubber in the new tissue increased during spring growth, becoming similar at the beginning of the dormant period to that of autumn in 1-year-old roots. The indexes of the sheath rubber are highest in early spring and exceed those of the new root tissue until June, when depolymerization occurs as the sheath is destroyed. The acid no. of 2nd-year spring roots is 60% less than 1st-year autumn samples. Kok-sagyz can be harvested during the 1st 6 weeks of the 2nd yr. without loss of rubber quality. Nelson McKaig, Jr.

Biochemical features of alpine fodder plants. S. O. Grebinskiĭ. *Compt. rend. acad. sci. U. R. S. S.* **24**, 513–16 (1939) (in English).—*Geranium collinum* Steph. (I) and leaves of *Ligularia macrophylla* D. C. (II), used as forage, were collected at altitudes from about 1500 to 3100 m. and analyzed. The whole plant and leaves of I increased in ash, N and ratio of sol. sugars to total carbohydrates and decreased in reserve carbohydrates (sol. in 2% HCl), cellulose and total carbohydrates with increase in altitude. Similar results were obtained for II except that ash decreased with increase in altitude because of thickening of the leaves. Nelson McKaig, Jr.

The effect of estrone and thyroxine on resting buds. Clara Zollikofer. *Ber. deut. botan. Ges.* **57**, 67–74 (1939).—Placing severed twigs in solns. of estrone for about 20 hrs. resulted in some stimulation of buds in *Corylus avellana*, *Forsythia viridis* and *Aesculus hippocastanum*. A concn. of 50 ME (Schering units) per l. was optimum for the catkins and 500 ME for the leaf buds. The action of thyroxine in stimulating the unfolding of leaves, observed by Hykes (*C. A.* **27**, 4557), was confirmed. Lawrence P. Miller

The significance of growth substance for the formation of adventitious shoots and roots. O. Fischnich. *Ber. deut. botan. Ges.* **57**, 122–34 (1939).—Further expts. confirm previous conclusions (*C. A.* **32**, 8482[8]) that high concns. of growth substance lead to root production, but low concns. favor shoot formation. Callus tissue which ordinarily would form roots could be induced to form shoots through lowering of the growth substance content by inverting the cutting or by removing portions of the bark. L. P. M.

The disappearance of the germinative capacity of seeds, especially of cereals. Georg Lakon. *Ber. deut. botan. Ges.* **57**, 191–203 (1939).—Loss of germinative capacity is a gradual process and in wheat, rye, barley and oats it is first manifested by the death of the cells of the radicle. Living embryos and living portions of partly dead embryos reduce Se salts to red metallic Se, and this test is recommended for detg. the germinative capacity of these seeds. Conditions are also given for using the Se test with corn, the embryos of which are difficult to excise, and which differ from the other seeds studied in that the cells forming the shoot are the first to become nonviable. L. P. M.

Photoperiodism and flowering hormones. H. Ullrich. *Ber. deut. botan. Ges.* **57**, General Meeting No., 40–52 (1939).—A review. Lawrence P. Miller

The significance of hydrocyanic acid in seed germination. Josef Keil. *Jahrb. wiss. Botan.* **88**, 345–72 (1939); cf. Laibach and Keil, *C. A.* **32**, 2980[8].—HCN is the germination-inhibiting substance in seeds contg. it; for normal germination of such seeds the presence of some HCN is, however, essential. The transport of β-indoleacetic acid is unaffected by HCN, but the response of the cells to growth substance is reduced when HCN is present. The seed coats have a regulatory effect on the action of HCN; thus, the testa of apple seeds can resorb considerable free HCN as well as amygdalin. L. P. M.

The detection of small quantities of growth substance. Hildegard Funke. *Jahrb. wiss. Botan.* **88**, 373–88 (1939).—A modified oat coleoptile test is described which, with natural auxin is 6–7 times, and with heteroauxin, 1.5–3 times more sensitive than previous tests, when small amts. are involved. Lawrence P. Miller

Talc as a carrier of substances inducing root formation in softwood cuttings. V. T. Stoutemyer. *Proc. Am. Soc. Hort. Sci.* **36**, 817–22 (1939); cf. Grace, *C. A.* **32**, 7071[9].—Treatments with dusts contg. indolebutyric acid and naphthaleneacetic acid were, in general, as effective as soln. treatments. High concns. in dust form were less injurious to sensitive tissues than in aqueous solns. A concn. of 1 to 1000 is suggested as an all-purpose dust. The addn. of thiourea in preliminary tests induced increased heaviness of root systems. Lawrence P. Miller

Effect of growth substances and maturity on rooting of cuttings of certain shrubs. L. E. Longley. *Proc. Am. Soc. Hort. Sci.* **36**, 827–30 (1939).—Treating cuttings for 20 hrs. with a soln. of indolebutyric acid contg. 2.2 mg. per 100 cc. in general increased rooting, although certain species which are difficult to root did not respond. Lawrence P. Miller

Histology and physiology of rotenoids in some Papilionaceae. I. R. R. Le Geyt Worsley. *Ann. Applied Biol.* **26**, 649–83 (1939).—Rotenoids (rotenone, tephrosin, deguelin, toxicarol) are defined by W. as naturally occurring substances which give a blue or green color when treated with strong HNO_3 soln. followed by strong NH_4OH soln. Twenty-two species of this plant family were examd. for rotenoids; the compds. were found in 14 species, the rotenoid content varying from traces in the seeds of 1 species to appreciable quantities in nearly every organ of another species. The seeds and roots of most species contained rotenoids. The occurrence of rotenoids in the various cells and tissues of the plants is described, and their fate in the germinating seed and young plant is followed. Rotenoids disappear in the germinating seeds of all species examd. and in the lignifying pith of the stems of 2 species. Expts. indicated that rotenone is not available as a food reserve. Rotenoids are probably of some direct use to the germinating seed and the seedling; but appear to be waste products in all other tissues. These substances are apparently confined to 2 plant subtribes, Tephroseae and Lonchocarpeae of the tribes Galageae and Dalbergeae. C. H. Richardson

Calculations of bioelectrical potentials. VI. Some effects of guaiacol on Nitella. W. J. V. Osterhout. *J. Gen. Physiol.* **23**, 171–6 (1939); cf. *C. A.* **33**, 8642[1].—The apparent mobilities and partition coeffs. of the alk. metals in the outer nonaq. layer of the protoplasm of *Nitella flexilis* were calcd. The order of mobilities resembles that in water; the partition coeffs., except for Cs, increase with the ionic radius. With Cl^- as unity, the following mobility values were found before and after exposure to guaiacol: Li 2.04, 5.83; Na 2.33, 7.30; K 8.76, 8.76; Rb 8.76, 8.76; Cs 1.72, 3.38; NH_4 4.05, 4.91; 0.5 Mg 20.7, 20.7; 0.5 Ca 7.52, 14.46. The partition coeffs., with KCl as unity, before and after exposure to guaiacol are: Li 0.0133, 0.149; Na 0.0263, 0.426; Rb 1.0, 1.0; Cs 0.0152, 0.82; NH_4 0.0182, 0.935; Mg 0.0017,

0.0263; Ca 0.02, 0.323. K is unchanged. The effect of guaiacol on the mobilities of the Na and K ions in *Nitella* resembles that in *Halicystis;* but in *Valonia* guaiacol increases the mobility of the Na ion and decreases that of the K ion. C. H. Richardson

Life factors in molecule building. J. N. Rakshit. *Chem. Products* **3**, 5–6(1939).—For a study of the mechanism of photosynthesis and the influence of the "life factor" in the formation of mols., oil-bearing grasses and plants were examd. Monthly examns. of oils were made. Yield, moisture, sp. gr., acid value, phenol value, aldehyde and ester value are tabulated for one series of samples from *Ocimum*. Leopold Scheflan

The role of sorbitol in the carbon metabolism of the Kelsey plum. I. Changes in the composition during growth and storage. Izak Donen. *Biochem. J.* **33**, 1611–20(1939).—The mature fruit contain an av. of 2.8% sorbitol most of which was accumulated during the latter part of the growth cycle. During storage the sorbitol seems to be lost before there is any loss of sugar. E. W. Scott

Studies in tree physiology. I. Introduction; water contents of certain Canadian trees. R. Darnley Gibbs. *Can. J. Research* **17, C**, 460–82(1939). **II. Seasonal changes in the food reserve of field birch (Betula populifolia Marsh).** *Ibid.* **18, C**, 1–9(1940).—During the period January, 1936 to July, 1938, the upper parts of *Betula populifolia* Marsh were analyzed for water, reducing sugars, sucrose, total sol. sugars, ether-sol. material, polysaccharide hydrolyzable by taka-diastase, and residual polysaccharides extd. by dil. acid. From 38 to 63% of the taka-diastasé hydrolyzate from the wood is nonfermentable, presumably pentose. The residual acid ext. is 69–100% nonfermentable. Hexosan is low in winter, rises to a max. just before leaf-opening, decreases sharply during spring growth and accumulates in summer. Ether-sol. material is not stored in winter. Sucrose and to a lesser extent reducing sugars are high in winter. There is a significant correlation between reducing sugars and water content of the twigs. Food reserves of the cortex behave much as do those of wood. J. W. Shipley

Vegetative propagation of conifers. IV. Effects of cane sugar, ethyl mercuric phosphate and indolylacetic acid in talc dust on the rooting of Norway spruce. N. H. Grace. *Can. J. Research* **18, C**, 13–17(1940); cf. *C. A.* **34**, 472[4].—Norway spruce cuttings collected in Nov. from the upper part of the tree were treated with a series of talc dusts contg. indolylacetic and naphthylacetic acids, each at 0, 1000 and 5000 p. p. m., combined with cane sugar at 0 and 10%, and Et mercuric phosphate at 0 and 50 p. p. m., and propagated in a greenhouse. Indolylacetic acid at 1000 p. p. m. increased rooting by about 10% to 42.5%, 3 months after planting, but at 5000 p. p. m. reduced it significantly. Naphthylacetic acid reduced rooting at both concns. Indolylacetic acid increased the length of root per rooted cutting. Sugar in combination with indolylacetic acid inhibited the increase in root length caused by the hormone alone: org. Hg alone or in combination with indolylacetic acid reduced root length, but sugar and Hg in combination exerted no greater inhibition than either alone. Mean root length was affected only by indolylacetic acid, which increased it. J. W. Shipley

Distribution of boron in the organs of Nicotiana rustica. Gabriel Bertrand and Lazare Silberstein. *Compt. rend.* **210**, 70–3(1940); cf. *C. A.* **33**, 8244[1].—The B content of *Nicotiana rustica*, gathered when it began to flower, averaged 7.4 mg. per kg. of dried material, but is very unequally distributed, being least (4–7 mg./kg.) in the roots and lower stalk, and most (10.5–13.5 mg./kg.) in the youngest leaves and inflorescence, except the corolla which contains only 3.2 mg./kg. The distribution resembles that in the lily (*C. A.* **32**, 3789[5]). C. A. S.

Chemical determination of ethylene in the emanations from apples and pears. Elmer Hansen and Bert E. Christensen. *Botan. Gaz.* **101**, 403–9(1939); cf. *C. A.* **33**, 8694[4].—A new procedure for C_2H_4 (*C. A.* **33**, 2938[8]) was applied to the emanations from apples and pears. Soly. tests showed that C_2H_4 is the active gas. C_2H_2, propylene and butylene were not found in amts. that could be detected by the bromination procedure. The amts. of C_2H_4 produced during ripening were 0.001 to 0.280 ml. per kg.-hr. J. T. Sullivan

The periodic partial failure of American cotton in the Punjab. I. Early breakdown of the photosynthetic apparatus. R. H. Dastur. *Indian J. Agr. Sci.* **9**, 285–90(1939); cf. *C. A.* **30**, 6785[2].—Different stages of the disintegration of the chloroplasts in 4F Punjab-American cotton (*G. hirsutum*) are described. Disintegration occurs in two ways, produced by mech. and chem. causes. The mech. decompn. of chloroplasts is caused by the daily increase in the size of the starch grains. The chloroplasts bulge, form a network with the starch grains in the meshes and become ruptured. Substances giving reactions of tannins are formed later in the cells. The appearance of minute pores marks the starting point of the chem. type of disintegration. The chloroplasts first swell and large cavities appear, then fuse together forming a spongy mass in the cells. Tannins develop and cover the dissolving chloroplasts. Both types of disintegration are produced experimentally in normal leaves, mech. rupture by interfering with the normal transport of carbohydrates from the leaves by ringing the stem, chem. disintegration by application of NaCl to the soil. The breakdown of the photosynthetic app. is found to occur prematurely in the leaves of plants that develop the external symptoms of the "disease" under investigation while no such disintegration of chloroplasts is noticed in the leaves of normal plants. **II. Formation and accumulation of tannins in the leaves.** *Ibid.* 291–303.—The accumulation of tannins giving the osmic acid test occurs in the leaves of plants which later develop the external symptoms of the disease, viz., the reddening and shedding of the leaves and the poor opening of bolls. Such accumulation does not occur at any stage in normal plants. The accumulation of tannins at an early stage can be regarded as an index of an abnormal and unhealthy condition. J. T. S.

The comparative composition of double and normal flowers. Cécile Sosa-Bourdouil. *Bull. muséum natl. hist. nat.* (Paris) **10**, 308–10(1938).—Detns. of moisture, reducing sugars, total C, H, N and sol. and protein N were made on normal and double flowers at comparable stages of development. The only important difference was that the double flowers contained a lower percentage of total N than the normal flowers, but showed no changes in the ratio of sol. to protein N. The total N (parts per 100 of dry wt.) for the normal and double flowers, resp., were: *Leucoium vernum*, 3.84, 2.75; *Anemone coronaria*, var. *Capelan*, 2.85, 2.44; *Matthiola incana*, 3.91, 3.50. W. C. Tobie

The floridean starch of Furcellaria fastigiata. Its seasonal variations. Ed. Gueguen. *Bull. soc. sci. Bretagne* **14**, Extra No., 55–63(1937); cf. *C. A.* **24**, 3033, 4805.—As a reserve carbohydrate, *Rhodymenia palmata* contains only floridoside (I) (cf. *C. A.* **24**, 4803); *Furcellaria fastigiata* contains I and starch. The starch was demonstrated and detd. by pancreatin-hydrolysis of the plant (after extn. of I with alc.) to yield glucose. Quant. values obtained in monthly analyses are tabulated. The approx. amts. of starch and of I in *Furcellaria fastigiata* and of I in *Rhodymenia palmata* (as parts per 1000 of fresh plant) are: October, 22, 13, 25; March, 0, 5.2, 3.5; September, 26, 8, 54. Conclusion: For correct values of carbohydrates in seaweeds, detns. must be made throughout the year, not in the summer alone. W. C. Tobie

Isolation of a crystalline selenium-containing organic compound from plant material. M. J. Horn and D. Breese Jones. *J. Am. Chem. Soc.* **62**, 234(1940).—Announcement is made of the isolation from plants of an *amino acid*, $C_{21}H_{44}N_6Se_2SO_{12}$; it decomps. 263–5° and has equiv. wt. 130.5; the N is all in the form of NH_2; it gives a strong ninhydrin reaction. C. J. West

The distribution and role of cane sugar in plants. John Parkin. *Gardeners' Chronicle* [3], **103**, 12–13, 112–13, 167, 240(1938).—A review of the sucrose-hexose and glucose-fructose ratios in plant leaves, photosynthesis in plants,

movement of carbohydrates in plants, presence of maltose in leaves, sugar in fruits, carbohydrate and sucrose chemistry, etc. Colin W. Whittaker

Absorption of calcium and formation of oxalic acid in higher green plants. Carsten Olsen. *Compt. rend. trav. lab. Carlsberg*, Ser. chim. **23**, 101-24(1939).—CaC_2O_4 (I) is deposited in the tissues of plants abundantly producing $H_2C_2O_4$ (II), and the amt. of II formed is largely detd. by the amt. of I pptd. In *Picea excelsa* the amt. of non-oxalate Ca (III) is practically const. In other species III increases when the Ca absorbed exceeds a limiting value, i. e., acid production cannot parallel Ca absorption under conditions particularly favorable to the latter. In *Fagus silvatica* (IV), a producer of II, 62% of all the Ca in the leaves is present as I, 9% is in soln. in the sap; therefore the dissolved Ca is but 25% of III. *Tussilago farfarus* does not form II, and only 35% of the leaf Ca is in soln. Ca and II increase in the leaves of IV and of *Primula elatior* throughout the summer. Malic acid (V) in largest amt. is found in young beech leaves free from II. As summer advances the amt. of V diminishes while that of II increases, and the pH of the sap increases from 3.8–6.0. *Dianthus barbatus* (VI), which produces II, when grown in H_2O contg. some Ca shows an increasing dry-material production with a decreasing Ca concn. With *Sinapis alba*, a nonproducer of II, the growth phenomenon is a direct function of the Ca content of the solution. *Spinacia oleracea* and VI, producers of II, thrive when N is supplied as $(NH_4)_2SO_4$. When a nitrate is used, contrary to the literature, less II is formed. NH_4 ions inhibit Ca absorption more than do those of K. Five tables and 5 sets of graphs are presented G. Albert Hill

The vitamin C content of various rosebushes and related plants. E. Zariņš and C. Putniņa. *Acta Univ. Latviensis, Kim. Fakultat.* Ser. 4, No. 10(in Lettish, 431–8; in German, 439-40)(1939).—Rosebushes at the botanical gardens of the Latvian university were harvested in October and stored at 4°. The fruit was ground in quartz sand and a mixt. of 2% *m*-phosphoric acid + 8% Cl_3-AcOH, pptd. with Hg acetate, reduced with H_2S, neutralized with $MgCO_3$ and titrated with 0.01 *N* 2,6-dichlorophenolindophenol soln.; this gave the total ascorbic acid + the dehydroascorbic content. A direct titration of the grindings gave the ascorbic acid content. The ratio of the ascorbic acid to the dehydroascorbic acid in various plants in mg. per 100 g. of fruit was determined. Fruits from the rosebush stored at 4° in the dark did not lose any of their vitamin C for several weeks. Frank Maresh

Ultraviolet spectrophotometry of *Zea mays* pollen with quartz microscope (Uber) **3**.

E—NUTRITION

PHILIP B. HAWK

Does the silver fox need vitamin C in its feed? Erling Mathiesen. *Norsk Pelsdyrblad* **1939**, No. 13, 456–7.—Feeding expts. with 3 groups of silver foxes, each comprising 5 animals, were raised on a food contg.: Group (1) cabbage as a source of vitamin C, (2) ascorbic acid, (3) neg. control without any vitamin C. The lack of vitamin C in the control group was proved by feeding expts. on guinea pigs that died in the regular time with typical scurvy symptoms. After 3 months' feeding expt. no difference in wt. and appearance of the foxes could be observed. Silver fox does not seem to have any need of vitamin C in its feed. V. Aschehoug

Vitamin B_1 deficiency in silver foxes. H. Kringstad and G. Lunde. *Norsk Pelsdyrblad* **1940**, No. 14, 5–8, 19–20.—Silver-fox pups fed a vitamin B_1-free diet showed cessation of growth, and afterwards decrease in wt. accompanied by cramps or paralysis. The animals died when no vitamin B_1 was administered. The same basal diet with an adequate amt. of vitamin B_1 insured normal development of the animals. No cramps occurred. Growth curves and illustrations of sick animals were given. The amt. of vitamin B_1 used in the expt. was 0.2 mg. (corresponding to 70 I. U.) vitamin B_1 per day per animal. This dose proved to be sufficient to prevent beriberi. The vitamin B_1 contents of the most important feeds are summarized. V. Aschehoug

Vitamin D in diet. J. Lindsay and V. H. Mottram. *Brit. Med. J.* **1939**, I, 14–15.—Palatable sources are described. B. C. P. A.

Review: Dietetics. Arno Ed. Lampé. *Jahreskurse ärtzl. Fortbild.* **30**, No. 8, 1–19(1939).—A brief review of recent work on important components (vitamins, inorg. constituents, amino acids, etc.) of some foods and on the dietetic treatment of certain diseases. Ruth Berggren

Experimental renal insufficiency produced by partial nephrectomy. XI. Diets containing dried extracted liver. Alfred Chanutin and Stephan Ludewig. *Arch. Internal Med.* **64**, 513–25(1939); cf. *C. A.* **32**, 7080⁴.—Diets contg. 10, 20, 40, 60 and 80% dried extd. liver were fed to rats with intact kidneys and to unilaterally nephrectomized and partially nephrectomized rats. The intact and unilaterally nephrectomized rats showed no effect on blood pressure by the diet. The kidney wt./surface area increased with protein intake, except with the 80% diet which gave a low ratio. The urea ratio per g. kidney was fairly const., indicating a direct relation between the degree of renal hypertrophy and renal function. In the partially nephrectomized animals the frequency and degree of hypertension were not related to the diet, most marked hypertension appearing in the 20% diet, and the lowest incidence in the 80% diet. The total solids of the kidney increased with increased protein intake. The 40% diet showed the most renal insufficiency. Except in the 80% diet, the blood urea and urine concns. increased with the protein intake. **XII. Diets containing dried extracted meat.** *Ibid.* 526–41.—Expts. similar to those in the previous report were carried out with dried extd. meat. Total solids of the kidney per unit of surface area increased progressively with increased dietary protein. Urinary vols. during concn. tests also increased. Greatest incidence of urines with low sp. gr. appeared in the 40, 60 and 80% ext. of meat diets. Proteinuria was highest and also the most marked changes in renal function occurred in the 40% diet. Renal insufficiency was greatest in this diet and least in the 80% diet. **XIII. A summary of the effect of whole liver, whole meat, extracted liver and extracted meat diets on renal hypertrophy, renal function, blood pressure and cardiac hypertrophy.** *Ibid.* 747–55.—Diets contg. protein components varying from 10 to 80% of whole meat, extd. meat, whole liver and extd. liver were fed for periods of 75–175 days to intact and to partially nephrectomized rats. In the intact rat each increment of the protein component generally caused progressive renal hypertrophy and an increase in the urea clearance. Variations in the protein content did not affect the vol. or sp. gr. during a concn. test with a 24-hr. specimen. The blood pressures and the size of the hearts were not appreciably affected by augmenting the protein components. The main effect of the type of protein component was manifested by the larger amt. of heart muscle per unit of surface area required to maintain a given blood pressure in the animals on the whole meat and whole liver diets. In the partially nephrectomized animals the effect of increasing the protein component of the diet was similar to that in the intact animals. **XIV. Diets containing dried whole yeast.** *Ibid.* 756–66.—In the partially nephrectomized animals there was a progressive increase in the dry kidney wt./surface area ratios with increasing concn. of yeast in the diet. The incidence of hypertension was greatest in the 60% yeast diet. No marked renal insufficiency was observed. J. B. B.

Biophotometer test as an index of nutritional status for vitamin A. Grace Steininger and Lydia J. Roberts. *Arch. Internal Med.* **64**, 1170–86(1939).—Results are given of over 2000 biophotometer tests on 459 persons and

the significance of the data is discussed. Although some relation exists between the biophotometer readings and the state of vitamin A nutrition, the relation is not close enough to warrant the use of the test as a means of diagnosing subclinical deficiency. J. B. Brown

Treatment of multiple sclerosis with nicotinic acid and vitamin B_1. Matthew T. Moore. *Arch. Internal Med.* **65**, 1-20(1940).—Nicotinic acid produces vasodilatation of the skin, brain and spinal cord. No harmful effects followed parenteral administration of 120 mg. of nicotinic acid and 33.2 mg. thiamine chloride daily for prolonged periods. J. B. Brown

Vitamin A deficiency in diabetes mellitus. J. G. Brazer and A. C. Curtis. *Arch. Internal Med.* **65**, 90-105(1940). —All of a group of 20 patients with juvenile diabetes have poor light adaptation. Daily administration of 60,000 U. S. P. units of vitamin A as cryst. carotene for 14 days was ineffective in improving the light adaptation, but the same dosage of vitamin A in the form of concd. fish oils caused a return to normal of light adaptation in 3-21 days. In such patients there appears to be inability to convert carotene to vitamin A. J. B. Brown

The relation of the anterior pituitary gland to carbohydrate metabolism. F. G. Young. *Brit. Med. J.* **1939, II**, 393-6.—A review. J. B. Brown

The antirachitic value of human milk. J. C. Drummond, C. H. Gray and N. E. G. Richardson. *Brit. Med. J.* **1939, II**, 757-60.—Twenty-six samples of human milk showed an av. of 6 I. U. vitamin D per 100 cc. with little or no seasonal variation. The vitamin content is affected by the diet. The contents of Ca and P, both total and dialyzable, in a no. of samples of human milk are included. The authors discuss at length the interrelationships between vitamin D, Ca and P in infant nutrition. J. B. Brown

The vitamin K activity of 2-methyl-1,4-naphthoquinone and its clinical use in obstructive jaundice. James M. Macfie, A. L. Bacharach and M. R. A. Chance. *Brit. Med. J.* **1939, II**, 1220-3.—Intramuscular injection of natural vitamin K concentrate in jaundice is ineffective in controlling hemorrhage, but the substitution of 2-methyl-1,4-naphthoquinone is effective in raising the prothrombin index. This compd. may be of value in the treatment of postoperative bleeding in jaundice. J. B. Brown

The significance of cevitamic acid deficiency in surgical patients. John A. Wolfer and Frederick C. Hoebel. *Surg. Gynecol. Obstet.* **69**, 745-55(1939).—Although there is no proof that vitamin C deficiency is related to nonunion of wounds, there is considerable evidence that such a relationship exists. Methods and dosage for obtaining vitamin C satn. are described. J. B. Brown

The newer knowledge of vitamin C in health and disease. E. Neige Todhunter. *J. Am. Dietet. Assoc.* **16**, 1-11(1940).—A discussion. E. Curzon

Recent vitamin research. II. Vitamins C, B complex and the less well-known vitamin factors. J. Ernestine Becker. *J. Am. Dietet. Assoc.* **16**, 16-33(1940); cf. *C. A.* **34**, 1358[8].—A review. 33 references. E. Curzon

Diseases of sheep with special reference to feeding troubles. A. C. Rosenberger. *Bull. Dept. Agr., Calif.* **27**, 242-7(1938).—General. C. R. Fellers

Protein levels of rations in growing chicks. A. E. Tomhave. *Del. Agr. Expt. Sta., Bull.* **214**, 15(1938), *Ann. Rept.* **1938**.—Reducing the protein level of the ration from 18.2% protein to 16% at the 9th, 10th, 11th and 12th week did not result in material decrease in wt. for White Leghorn and for Barred Rock pullets. More feed was required, however, to produce 1 lb. of gain where the protein was reduced. There was a direct relationship between the no. of bare-breasted birds and the level of protein fed. C. R. Fellers

Adaptation to a low-calcium intake in reference to the calcium requirements of a tropical population. Lucius Nicholls and Ananda Nimalasuriya. *J. Nutrition* **18**, 563-77(1939); cf. Ceylon Govt. Press, *Sessional Paper XXIX*(1937).—Accepted standards for daily Ca intake in Europe and America are too high. A metabolic adaptation to a low-Ca diet is shown by, (1) the low amts. of Ca in the urines of those on low-Ca diets, when compared with the amts. in the urines of those on high-Ca intake; (2) the high percentage of Ca retention by growing children on about 0.2 g. of Ca daily. The Ca contents of many skeletons of children and adults were detd. Daily standard Ca allowances are suggested as follows: age 1-7 years, 0.5 g.; age 7-12 years, 0.75 g.; age 12-20 years, 1.0 g. A standard allowance of 0.5 g. Ca is sufficient for adults, excluding lactating women. C. R. Fellers

The role of the antidermatosis vitamin and a new water-soluble growth factor in the nutrition of the mature fowl. J. C. Bauernfeind and L. C. Norris. *J. Nutrition* **18**, 579-91(1939); cf. *C. A.* **33**, 6406[6].—An exptl. diet deficient in the vitamin was developed by subjecting the cereal portion and the liver ext. to prolonged dry heat-treatment and the casein to special purification (not given). The diet was adequate in vitamins A, B, B_4, B_6, D, E, G, K and the antiencephalomalacia factor. Nicotinic acid was found either to be present in the diet or else not needed in avian nutrition. This diet when supplemented with the antidermatosis vitamin (filtrate factor) was deficient in another new factor required for chick growth. This factor is not identical with any of the known vitamins. It is destroyed by prolonged dry heat-treatment, stable in yeast to autoclaving, water-sol., adsorbable upon fuller's earth and present in milk, liver, yeast and fresh green grass. Both the antidermatosis vitamin and the new factor were necessary for reproduction in the hen. Supplementing the deficient diet with both factors, however, failed to promote normal reproduction or to maintain the wt. of the hens, but egg production was satisfactory. 27 references. C. R. Fellers

Simplified rations for the chick. A. G. Hogan and L. R. Richardson. *J. Nutrition* **19**, 1-11(1940); cf. *C. A.* **30**, 750[7].—If vitamins A, B_1, B_2 and D are otherwise provided, then all the unrecognized vitamins required by the chick are present in aq. and alc. exts. of liver. Partial sepn. of the unidentified essential nutrients can be attained by extg. first with EtOH and then with H_2O. Both exts. must be present if the ration is to be adequate. Tikitiki contains an essential nutritive element but this same nutrient seems also to be present in the EtOH-sol. fraction of liver in even greater concn. C. R. Fellers

Adequacy of a milk diet for the rat. Luther R. Richardson and Albert G. Hogan. *J. Nutrition* **19**, 13-19(1940). —Milk is apparently deficient in some nutrient other than Fe, Cu, Mn or I, which is essential for normal reproduction in the rat. The exptl. rats produced only $1/2$ as many litters per female as did the controls. The reproductive performance of the 4th generation was not inferior to that of any of the preceding three. C. R. Fellers

Biological assay of thiamine with chicks. Thomas H. Jukes and Hubert Heitman, Jr. *J. Nutrition* **19**, 21-30 (1940); cf. *C. A.* **34**, 4775.—A method is described using a basal diet consisting principally of polished rice, fish meal and autoclaved yeast. A response curve was drawn in which the level of thiamine added to the diet is compared with the "polyneuritic mortality index," the latter value being expressive of the degree of protection afforded by a suboptimal level of thiamine fed during the assay period of 28 days. The thiamine requirement of the chick was estd. as between 130 and 150 γ of thiamine-HCl per 100 g. of diet for the prevention of polyneuritis. The thiamine content of the polished rice used in the basal diet was about 0.4 γ per g. A growth factor essential for the chick, absent from autoclaved yeast, was found to be present in polished rice. C. R. Fellers

Prevention of hyperplasia in the forestomach epithelium of rats fed white flour. George R. Sharpless. *J. Nutrition* **19**, 31-7(1940); cf. *Ann. Surg.* **106**, 502(1937). —Hyperplasia of the squamous epithelium in the forestomach of rats fed a diet of white flour is prevented by adding lactoflavin, nicotinic acid, cystine and rice polish concentrate to the diet. With a diet of white flour, protein or starvation is not an important factor in production of the lesions. The relation of local irritation to formation of the lesions and the relation of the nonspecific protective factors to sensitivity of epithelial cells to proliferative stimuli is discussed. C. R. Fellers

State of vitamin A in the liver of the rat after feeding various forms of the vitamin. E. LeB. Gray, K. C. D. Hickman and Elizabeth F. Brown. *J. Nutrition* 19, 39–46(1940).—Vitamin A, fed to rats in the following forms: U. S. P. Reference Oil, vitamin A caproate, distd. ester concentrate, vitamin A stearate, vitamin A alc. and β-carotene, was recovered in the livers as the esters, the percentage recovery being in the order of the substances listed. 55.6% of the vitamin fed as U. S. P. Reference Oil was recovered, as against 39.3% recovery from that fed as alc. and 9.7% recovery from β-carotene. A small amt. of the vitamin alc. was always present, the significance of which is at present unknown. The type of ester in each case was similar, which suggests a selective utilization of fat acids by the rat for the purpose of esterifying the vitamin. C. R. Fellers 1

Choline in the diet of chickens. O. D. Abbott and C. U. DeMasters. *J. Nutrition* 19, 47–55(1940).—The addn. of choline to the basal diet increased egg production, decreased mortality, inhibited abortion of egg yolks, and decreased the percentage of fat acids in the livers. The concn. of fat acids in the livers of the males fed diets with and without choline was considerably lower than that in the livers of pullets fed the same rations. C. R. F. 2

Quantitative requirements of the components of the vitamin B complex for lactation and growth of nursing young of the albino rat. Barnett Sure and Alethea Beach. *J. Nutrition* 19, 57–69(1940); cf. *C. A.* 24, 5339.—Following depletion of vitamin B reserves, the rearing of the young rat can proceed at a rate comparable with that secured on an optimum stock diet when the following supplements are furnished daily to the mother: 120 γ thiamine, 120 γ riboflavin, 50 γ vitamin B_6, 15 mg. choline chloride, 1 cc. of a soln. of "W" factor equiv. to 1 g. of liver ext., and 6 mg. nicotinic acid. It was not detd. whether the nicotinic acid is really essential for the lactating rat. 31 references. C. R. Fellers 3

Essential nature of choline for lactation and growth of the albino rat. Barnett Sure and Alethea Beach. *J. Nutrition* 19, 71–6(1940).—Choline was indispensable for growth and lactation. C. R. Fellers 4

Influence of the nitrogen content of the diet on the calorie balances of pre-school children. Jean E. Hawks, Jeanne M. Voorhees, Merle M. Bray and Marie Dye. *J. Nutrition* 19, 77–89(1940); cf. *C. A.* 32, 5450[1].—Five pre-school children served as subjects for 2 long-time balance expts., in each of which they received 2 diets, (1) contg. 3 and (2) contg. 4 g. of protein per kg. of body wt. The increase in protein content of the diets did not change the const. level of cal. utilization. Excretory values for both groups were remarkably const. and the retention figures varied in the same manner and to the same degree as the intake values. The change from the 3- to the 4-g. protein diet increased the N content of the excreta, thus increasing the actual no. of cal. eliminated. It also increased the av. proportion of the intake cal. eliminated from 7.3 to 12%. Thus, subtracting 10% from the intake values to care for excretory losses does not always give accurate results. The change also reduced the actual no., as well as the percentage, of the intake cal. available for body needs, but at the same time it produced greater wt. gains in the children. C. R. Fellers 5

Minimum vitamin A and carotene requirements of mammalian species. H. R. Guilbert, C. E. Howell and G. H. Hart. *J. Nutrition* 19, 91–103(1940); cf. *C. A.* 33, 8709[8].—In the horse the 1st detectable symptom of vitamin A deficiency is night blindness. The depletion time for the Percheron colts varied from 265 to 439 days. The horses at depletion were nervous and irritable. One I. U. of vitamin A from the U. S. P. Reference Oil was equiv. to 0.21 γ of carotene. Vitamin A and β-carotene requirements expressed in γ per kg. body wt. are for cattle 5.1–6.4 and 26–33; sheep 4.3–6.3 and 25–35; swine 4.4–6.3 and 25–39; horse 4.2–5.3 and 20–30; rat 4.6–5.3 and 15–20. The necessity for 2 standards for expressing requirements, 1 for vitamin A and 1 for carotene, is pointed out. C. R. Fellers 6

Vitamin A prevents "cottonseed meal injury." A. H. Kuhlman, Earl Weaver and W. D. Gallup. *Okla. Agr. Expt. Sta., Ann. Rept.* 1936–38, 67–8(1939); cf. *C. A.* 30, 2236[9].—The fact that cottonseed meal is not toxic when fed to dairy cattle is again verified. The supposed toxicity is really an avitaminosis A in the ration. Even when fed in amts. greatly in excess of the quantities usually fed, no injury to animals results. C. R. Fellers 7

Over ten percent fiber in chick rations is undesirable. Robert Penquite. *Okla. Agr. Expt. Sta., Ann. Rept.* 1936–38, 156–7(1939); cf. *C. A.* 30, 2236[7].—Various percentages of ground peanut hulls were used in chick rations for chicks up to 12 weeks old. The optimum amts. of fiber were from 4 to 10%. Decreased growth, higher mortality and retarded feather development were noted when the fiber content of the ration exceeded 10%. A chem. analysis of the amt. of crude fiber in a ration gives little information about its bulk. Nontoxic fiber fed to chicks in excessive amts. probably serves mainly as a diln. factor. C. R. Fellers 8

Turkey-nutrition investigations. T. T. Milby. *Okla. Agr. Expt. Sta., Ann. Rept.* 1936–38, 168–80(1939).—Turkeys require more protein than chicks. Approx. 22.4% protein in the ration gave as good growth and development as larger amts. When properly supplemented, frozen or dried *grasshoppers* are a valuable protein and fat component in the ration of turkeys. This is contrary to previous findings. Dried, ground grasshoppers substituted for a mixed protein supplement on an equal crude protein basis did not support normal growth, but frozen grasshoppers, supplemented with animal protein produced excellent wt. gains. Turkeys require more fiber than chickens, inasmuch as 20% ground peanut hulls in the ration gave best results (cf. preceding abstr.). C. R. Fellers 9

The vitamin A-suppressing factor in soybeans. S. M. Hauge, J. H. Hilton and J. W. Wilbur. *Purdue (Ind.) Agr. Expt. Sta., Rept. of the Director* 1937, 8–9, 40; cf. *C. A.* 31, 5466[9].—Soybeans contain a factor which interferes with the transference of vitamin A potency (carotene) of the ration to the milk fat secreted by the cows. The factor is present in the oil and is adsorbed by activated C (Nuchar). The vitamin A content of the butter was affected most. There was little or no effect on the carotene content of the butter. Extn. of soybeans with hexane, Et_2O or acetone did not remove the suppressing factor. C. R. Fellers 10

The composition of optimal and marginal diets. A. L. Bacharach and J. C. Drummond. *Chemistry & Industry* 1940, 37–40. G. G. 11

Comparative activity of vitamin H, curative of egg-white injury, administered orally and parenterally to rats. Paul György and Catharine S. Rose. *Proc. Soc. Exptl. Biol. Med.* 43, 73–4(1940).—The factor or vitamin (cf. *C. A.* 34, 480[7]) is 3–5 times more effective when given parenterally. L. E. Gilson 12

Negative effect of synthetic vitamin B_6 hydrochloride in nutritional deficiency in man. Robert Kark, Eugene L. Lozner and Arnold P. Meiklejohn. *Proc. Soc. Exptl. Biol. Med.* 43, 97–9(1940).—Report of 6 cases. L. E. Gilson 13

Identity of natural and synthetic crystalline vitamin B_6. E. J. Reedman, W. L. Sampson and K. Unna. *Proc. Soc. Exptl. Biol. Med.* 43, 112–15(1940); cf. *C. A.* 34, 477[8].—Rat curative and prophylactic tests show that natural and synthetic B_6 are identical in their physiol. action. A single dose of 50 γ cures severe symptoms of B_6 deficiency in 70–80% of the test rats within 14 days. Ten γ per rat per day insures normal growth. L. E. Gilson 14

Toxicity of vitamin B_6. Klaus Unna and Wm. Antopol. *Proc. Soc. Exptl. Biol. Med.* 43, 116–18(1940).—The toxicity for rats, dogs and monkeys is very low. The median subcutaneous lethal dose for rats was 3.1 g./kg. for the free base and 3.7 g./kg. for the hydrochloride. Death was preceded by tonic convulsions lasting 36–72 hrs. Dogs given 20 mg./kg. daily by mouth for 75 days were not injured in any way. L. E. Gilson 15

Antidermatitic effect of vitamin B_6 analogs. Klaus

Unna. *Proc. Soc. Exptl. Biol. Med.* **43**, 122–4(1940).— Ten derivs. were studied. The di- and triacetates of B_6 were as potent as B_6, on an equimol. basis. Probably they are hydrolyzed after absorption. Methylation or ethylation of one of the hydroxymethyl groups diminished the vitamin activity considerably but less than the methylation of the phenolic OH. Replacement of one or more hydroxymethyl groups by Me or NH_2 groups destroyed the vitamin activity. L. E. Gilson

Isolation, determination and synthesis of vitamin B_6 and vitamin K. C. R. Addinall. *Merck Rept.* **48**, No. 3, 8–11; No. 4, 16–20(1939).—Brief reviews. S. W. G.

Agranulocytosis and vitamin C. H. Kalk. *Deut. med. Wochschr.* **65**, 1624–9(1939).—Injection of ascorbic acid gave dramatic therapeutic effects in 6 patients suffering from agranulocytosis. This therapy was ineffective in the leucemias. Arthur Grollman

Hypovitaminosis B_1 and cardiopathies. III. The aggravating action of vitamin B_1 deficiency on the cardiac disturbances of hyperthyroidism and diabetics and on ordinary cardiopathies. Georges Bickel. *Arch. maladies coeur vaisseaux* **32**, 869–78(1939); cf. *C. A.* **34**, 1058[3].—A review with 31 references. Marion Horn

Pine disease in sheep. H. H. Corner. *Agr. Progress* **16**, 181–7(1939).—Administration of 1 mg. Co as $CoCl_2$ per day for 14 days was sufficient to maintain sheep in a healthy state for 6 months on land where the pine disease was prevalent. A similar quantity was effective as a cure. In practice, administration of Co to affected sheep resulted in a recovery rate of 97.6%. A mineral mixt. contg. sterilized steamed bone flour 1 cwt., NaCl 1 cwt. and $CoCl_2$ 1 oz. gives satisfactory results. K. D. Jacob

Milk corrects calcium deficiency. Charles F. Nelson. *Milk Plant Monthly* **28**, No. 11, 35 6(1939).—Clinical studies indicate that nearly 70% of human diets are deficient in Ca. Many diets are also low in P_2O_5. Milk corrects these deficiencies in the diet and reduces diseases due to them. A. H. Johnson

The effect of hot alcohol on purified animal proteins. Robert L. Harris and H. A. Matill. *J. Biol. Chem.* **132**, 477–85(1940); cf. *C. A.* **29**, 6929[2].—A lowered nutritive value of heat- or alcohol-treated proteins may be caused primarily by the formation of new enzyme-resistant configurations involving essential amino acids. The amt. of free amino N in liver and kidney globulins is decreased 50% by hot alc. extn., possibly because of the formation of new anhydride linkages involving the ε-amino group of lysine and available OH groups since there was no loss in total N. Both liver and kidney globulins lose much of their S as H_2S. Liver globulin II showed a marked decrease in digestibility by pancreatin *in vitro* and was the only protein fraction to show this effect. The proteins of the liver and kidney were fractionated according to the method of Luck (*C. A.* **30**, 8256[9]). A. P. Lothrop

Diphtherial intoxication and vitamin C content of the suprarenals of guinea pigs. Calvin C. Torrance. *J. Biol. Chem.* **132**, 575–84(1940); cf. *C. A.* **32**, 219[9]; **33**, 8284[3].—No significant differences were found between the vitamin C content of the suprarenal glands of guinea pigs injected with a sublethal dose of diphtheria toxin and that of the control animals. After injection of a small dose of toxin the ascorbic acid content of the suprarenals of both the control and exptl. animals on the same diet increased steadily for 8 days. In another expt. with a different group of animals a significant decrease in the vitamin C content of the suprarenals occurred 48 hrs. after the injection of the same dose of toxin. This dose, while not customarily fatal to animals weighing from 230 to 280 g., apparently caused the death of 2 of the 17 animals because of a seasonal increase in susceptibility. Amts. of toxin which are usually fatal were assocd. with significant decreases in the ascorbic acid content of the suprarenals. With those which are always fatal, the changes were even more marked. It appears, therefore, that the smallest amt. of toxin which will affect the vitamin C content of the suprarenal glands is the least dose which will prove fatal to some of the test animals and that this dose varies with the susceptibility. The problem of demonstrating beyond question that diphtheria toxin and vitamin C do not combine in the tissues is an extremely difficult one, but in these expts. no evidence of a direct combination was obtained. The burden of proof must rest with those who hold otherwise, since no evidence of such a combination *in vitro* has been obtained. A. P. Lothrop

Choline metabolism. II. The interrelationship of choline, cystine and methionine in the occurrence and prevention of hemorrhagic degeneration in young rats. Wendell H. Griffith and Nelson J. Wade. *J. Biol. Chem.* **132**, 627–37(1940); cf. *C. A.* **34**, 499[2].—The characteristic signs of hemorrhagic degeneration in rats produced by a low-choline basal diet are all intensified by the addn. of cystine and prevented by the addn. of methionine to the diet. It appears, therefore, that these 2 amino acids are concerned with this new dietary deficiency and that their amts. in proteins in part det. the requirement of the young rat for choline. The injurious effect of cystine is prevented by relatively small amts. of choline and this fact may be of importance in explaining many reports in the literature of the damaging action of cystine and of various proteins on the kidneys. **III. The effect of cystine, fat and cholesterol on hemorrhagic degeneration in young rats.** W. H. Griffith. *Ibid.* 639–44.—Supplements of cystine, fat or cholesterol increase the severity of the hemorrhagic degeneration occurring in young rats on a low-choline, low-fat and low-cholesterol diet. These toxic effects are prevented by choline. The results suggest that hemorrhagic degeneration is a manifestation of the same deficiency which results in fatty and cholesterol livers in older rats on a low-choline diet. However, the effect of choline deficiency in young rats is not limited to a relatively noninjurious deposition of liver lipides, but the kidney, particularly, undergoes an extremely rapid and acute hemorrhagic degeneration which may result in death within 10 days. It has not yet been detd. whether this new aspect of choline deficiency is another phase of abnormal lipide metabolism or whether a new role of choline in the body is involved. A. P. Lothrop

Vitamins and their analysis. P. Karrer. *Mitt. Lebensm. Hyg.* **30**, 131–47(1939).—A review. W. J. P.

The liver and carbohydrate metabolism. Samuel Soskin. *Endocrinology* **26**, 297–308(1940).—Carbohydrate metabolism represents a dynamic balance between blood-sugar formation in the liver and its utilization by the body tissues. Any disturbance in carbohydrate metabolism is likely to affect both sides of the equil., whether directly or by secondary compensatory changes. All problems concerned with carbohydrate metabolism must therefore be considered from both aspects. Felix Saunders

The adrenal cortex and carbohydrate metabolism. C. N. H. Long, B. Katzin and Edith G. Fry. *Endocrinology* **26**, 309–44(1940).—Adrenalectomized mice and rats maintained on Na salts retain practically normal carbohydrate levels when fed, but on fasting the levels decline more rapidly than in normal animals. Fasted adrenalectomized animals also excrete less urine N. The administration of cortical ext. or active cryst. adrenal steroids to either fasted normal or adrenalectomized mice and rats is followed by large increases in liver glycogen and slight hyperglucemia. The muscle glycogen is not affected. At the same time there occur increases in N excretion of sufficient magnitude to suggest that the increased protein catabolism is the source of this newly formed carbohydrate. In fed animals very large quantities of glycogen accumulate in the liver and under these circumstances the muscle glycogen may also increase. When the disposition of a known quantity of absorbed glucose is followed in rats it is found that the administration of cortical ext. apparently decreases the proportion of glucose oxidized while there is an increased proportion deposited as liver glycogen. In partially pancreatectomized rats adrenalectomy with subsequent maintenance on Na salts decreases glucose excretion and administration of cortical ext., corticosterone, etc., by mouth either exacerbates the glucosuria of animals with intact adrenals or causes its reappearance in adrenalectomized animals maintained on Na salts. Desoxycorticosterone has only a feeble effect. Not only is

the general condition of fasted hypophysectomized rats greatly improved by the injection of cortical ext., but also the liver glycogen and blood glucose of these animals are increased to supernormal levels. The urine N excretion is also increased. Cortical ext. is "diabetogenic" in fasted hypophysectomized-depancreatized rats in the sense that it increases the blood glucose and urine N. Expts. on the "diabetogenic" effect of anterior pituitary ext. in adrenalectomized-depancreatized animals indicate that not all this activity is mediated by the adrenal cortex, but rather that a synergism exists between the 2 hormones. It is suggested that 1 of the properties of the cortical hormone is a stimulation of protein catabolism, and that the increased carbohydrate levels, N and K excretion following its injection into animals is an expression of this effect.
Felix Saunders

The pituitary gland and carbohydrate metabolism. F. G. Young. *Endocrinology* **26**, 345–51(1940).—A review.
Felix Saunders

The V-factor content and oxygen consumption of tissues of the normal and blacktongue dog. Henry I. Kohn, James R. Klein and Wm. J. Dann. *Biochem. J.* **33**, 1432–42(1939).—The concn. of coenzyme-like substances (V-factor) was detd. in the brain, heart, striated muscle, liver, kidney, pancreas and blood of dogs (*a*) with acute blacktongue due to nicotinic acid (I) deficiency, (*b*) in normal health immediately after cure of blacktongue with small doses of I and (*c*) in normal health after receiving large amts. of I. The O consumption of brain, liver, kidney and striated muscle was studied *in vitro*. The concn. of V-factor was 70% lower in the liver and 35% lower in the muscle of the dogs in group (*a*) compared to these tissues from dogs in group (*c*). In dogs in group (*b*), the liver and muscle were 45% and 25% lower, resp. No differences were found in the other tissues examd. The decrease in coenzyme content of the liver was accompanied by an increase of 35% in the O consumption; in kidney the coenzyme content was unchanged, but ability to oxidize lactate was decreased by 50%. In blacktongue the percentage of coenzyme in the reduced form was increased in most tissues except brain and kidney. No evidence was found to indicate that blacktongue results from a generalized decrease of coenzyme level in the tissues.
E. W. Scott

The metabolism of pyruvic acid in normal and vitamin B_1-deficient states. IV. The accumulation of pyruvic acid and other carbonyl compounds in beriberi and the effect of vitamin B_1. B. S. Platt and G. D. Lu. *Biochem. J.* **33**, 1525–36(1939); cf. *C. A.* **33**, 8727[3].—The results of a comparative study of the bisulfite-binding substances and pyruvic acid in the blood, milk and urine, of normal and vitamin B_1-deficient human subjects were given. The pyruvate level in normal human blood was of the order of 0.5 mg./100 g. Maintained raised levels of blood pyruvate seemed to be specifically assocd. with vitamin B_1 deficiency. In the rapidly developing fulminatory types of beriberi the initial level of blood pyruvate was a definite indication of the degree of the deficiency.* Several hrs. were required for the removal of accumulated pyruvate after administration of vitamin B_1; about 5 mg. was necessary to restore the pyruvate to normal. **V. The effect of exercise on blood pyruvate in vitamin B_1 deficiency in man.** G. D. Lu and B. S. Platt. *Ibid.* 1538–43.—In subjects deficient in vitamin B_1 exercise caused an increase in the blood pyruvate. Values as high as those found in fulminating beriberi were sometimes obtained after heavy exercise. Even after light work, the pyruvate level was maintained for 30 min. In normal subjects there was no appreciable increase unless the subject was exhausted and then the return to normal was attained in less than an hr. **VI. The fate of injected pyruvate in the normal rabbit.** G. D. Lu and D. M. Needham. *Ibid.* 1544-8.—Estns. of carbohydrate changes in the blood of normal rabbits immediately after the injection of pyruvate indicated that the injection caused a sudden increase of nonglucose-reducing substance and also lactate which later gave rise to glucose. Only 2–3% was found in the muscles 8 min. after the injection of pyruvate. There was little or no change in the muscle lactate or glucose. When small amts. of pyruvate were injected, there were no changes in the phosphate partition in the blood or muscles. Lactic acid was formed *in vitro* by incubating blood with pyruvic acid if hexose diphosphate and adenylic acid were present. This suggests that pyruvate removal *in vivo* may be closely bound with this important energy-yielding oxidation-reduction.
E. W. Scott

Diffusion of radioactive sodium into the muscles of potassium-deprived rats. Leon A. Heppel. *Am. J. Physiol.* **128**, 449–54(1940); cf. *C. A.* **33**, 8728[7].—The penetration of Na into the muscles of K-deprived rats was studied by means of the radioactive isotope of Na. Both the extracellular and intracellular fractions of the muscle Na exchanged readily with the Na in the plasma. The membranes of the muscle cells were apparently permeable to Na. In K-deprived rats a decrease was found in the content of K in spleen, kidney and heart, but the changes were small compared to the loss incurred by skeletal muscle.
E. D. Walter

The relation of diet to the restitution of the gonadotropic hormone content of the discharged rabbit pituitary. Maurice H. Friedman and Gertrude S. Friedman. *Am. J. Physiol.* **128**, 493–9(1940); cf. *C. A.* **33**, 5475[1].—The rabbit pituitary is more responsive to seasonal influences than to changes in dietary protein. It appears that the protein requirements for the formation of the gonadotropic hormone can be fully met by nitrogenous products derived from the tissues of the rabbit even during the stress of serious N deficit.
E. D. Walter

The water content of various organs of the albino rat on a high-carbohydrate and a high-fat diet. John Haldi and Glenville Giddings. *Am. J. Physiol.* **128**, 537–43 (1940).—The effect of prolonged feeding of a high-carbohydrate and a high-fat diet on the H_2O content of the organs of the albino rat was detd. on both nonexercising and exercising animals. No sex difference was found in the percentage of H_2O in the various organs except in the case of the kidneys on both diets in the nonexercise series and on the fat diet in the exercise series. Exercise had no effect on the hydration of the organs. Neither diet had any effect on the hydration of the heart, lungs, gonads and pituitary. Both diets had a dehydrating effect on the brain, spleen and adrenals. The carbohydrate diet produced a slight increase in the H_2O content of the muscle, whereas the fat diet had a dehydrating effect on the liver, kidneys, thymus and thyroid. Ketosis played no part in the results of these expts. as the urinary excretion was within the normal range.
E. D. Walter

The relation of the anterior pituitary and the adrenal cortex in the metabolism of carbohydrate. Jane A. Russell. *Am. J. Physiol.* **128**, 552–61(1940); cf. *C. A.* **33**, 7860[4].
E. D. Walter

Rat bradycardia. D. G. H. MacDonald and E. W. McHenry. *Am. J. Physiol.* **128**, 608–14(1940).—From the effect of injections of various B vitamins to deficient rats, of daily injections of various B vitamins to paired-fed rats and from the equal effects of thiamine and yeast on paired and *ad lib.* diets it is apparent that thiamine alone of the members of the vitamin B complex studied is effective in reducing rat bradycardia. That bradycardia is not solely the result of inanition was shown in paired feeding expts.; animals receiving thiamine had a rate considerably above those of the basal group. The quantity of food consumed was shown to be a factor in causing bradycardia. Bradycardia is not relieved by administration of thiamine unless food is also given. A sparing action of dietary fat on thiamine requirement for the prevention of bradycardia has been shown.
E. D. Walter

Spectacled eye condition in rats. J. J. Oleson, C. A. Elvehjem and E. B. Hart. *Proc. Soc. Exptl. Biol. Med.* **43**, 161–4(1940); cf. *C. A.* **33**, 2564[7]; **34**, 477[6], 491[5].—Corn-germ oil healed the spectacled eye condition. α-Tocopherol did not, fuller's earth filtrate of liver ext. did, though slowly. The factor concerned is not identical with any of the common vitamins, pantothenic acid, factor W, or the factor which prevents nutritional achromotrichia.
L. E. Gilson

Optical activity of vitamin C (Jirgensons) 10. Effect of refining on digestibility [and vitamin content] of edible oils and fats (Menezes, Banerjee) 27.

The New York Hospital Handbook of Applied Nutrition. New York: New York Hospital. 130 pp. $2.00.

F—PHYSIOLOGY

HOMER W. SMITH

The action of estrogens in inducing mitoses in the muscle, connective tissue and epithelium of the prostate and seminal vesicle of mice as determined by the colchicine technique. Richard Tislowitz. *Anat. Record* **75**, 265–73(1939).—Diethylstilbestrol produces changes in the prostate and seminal vesicle similar to those induced by estrogens with the steroid structure. P. D. Adams

Biological activity of methyldihydrotestosterone, a synthetic male-sex hormone. III. Effect on castrated young male rats, with special reference to the histological structure of the hypophysis. Saburo Ugami. *Bull. Inst. Phys. Chem. Research* (Tokyo) **17**, 853–7(1938); cf. *C. A.* **32**, 7976⁹.—The effect is described of different daily doses of the hormone on the wt. of the seminal vesicles, prostate, penis, hypophysis, adrenals, thymus, kidneys and heart, and on the structure of the hypophysis. In general it counteracts the effect of castration. **IV. Effect on normal young male rats, with special reference to the effect on the testis.** Saburo Ugami and Syuhei Susuki. *Ibid.* 858–63.—The effect of different daily doses on the wt. of the testicles, epididymis, hypophysis, seminal vesicles and adrenals is described. In the first two cases large doses have less effect than smaller ones. B. C. P. A.

Advances in the domain of experimental physiology. E. Schütz. *Jahreskurse ärtzl. Fortbild.* **30**, No. 9, 1–14 (1939).—A brief review of recent work on heat regulation and brain physiology and the important role of CO_2 is included. Ruth Berggren

Bilirubin and urobilin content of bile obtained by duodenal drainage. Normal values and values for patients with cholecystitis. M. Royer. *Arch. Internal Med.* **64**, 445–56(1939).—Bilirubin and urobilin concns. are greater in bladder bile than liver bile, but the concn. of urobilin is not so increased as bilirubin; this is due to the fact that the former is absorbed by the walls of the gall bladder. In cholecystitis production of urobilin has been observed in the gall bladder in nearly half the cases. J. B. Brown

Basal secretion of digestive enzymes in old age. Jacob Meyer, E. Spier and F. Neuwelt. *Arch. Internal Med.* **65**, 171–7(1940).—Salivary amylase is decidedly reduced in old age, whereas pancreatic amylase is only slightly lowered. In the very old the latter may approach the values found in the young. Lipase is unchanged with age. The proteolytic enzymes, trypsin and pepsin, are lowered with age. J. B. Brown

Iron transportation and metabolism. III. The normal fluctuations of serum and "easily split off" blood iron in individual subjects. Carl V. Moore, Virginia Minnich and Jo Welch. *J. Clin. Investigation* **18**, 543–52(1939); cf. *C. A.* **31**, 7956⁷·⁹.—The conditions affecting the color intensity and stability of ferric thiocyanate in isoamyl alc. were studied. The color was const. for an hr. in a dark room; it was unchanged in intensity and quality in 2–4 *N* acid; it was directly proportional to the amt. of Fe present in ranges from 0.05 to 1.0 mg. % serum Fe. Variations within the daily cycle and over a 6-mo. period were 0.01 to 0.065 mg. %. Liver and Fe medication had no effect on the serum-Fe level. "Easily split off" Fe varied in normal subjects as much as 1.48 mg. %; it is probably not concerned with Fe transport. **IV. Observations on the absorption of iron from the gastrointestinal tract.** Carl V. Moore, Wm. R. Arrowsmith, Jo Welch and Virginia Minnich. *Ibid.* 553–80.—Absorption of Fe from the gastrointestinal tract was studied by following the increase of serum Fe. This increase is a relative measure of the rate of Fe absorption, although it does not represent the entire absorption, since Fe is being continually withdrawn from the serum. With rise in serum Fe there is a small concurrent rise in lymph Fe. The rate of absorption (height of serum-Fe curve) is directly proportional to the dose up to the point of intestinal irritation. Water-sol., highly ionized ferrous salts were about equally absorbed in patients with either normal or achlorhydric gastric juices. Ease of ionization seems to be the detg. factor under these conditions. Fe seems to be absorbed primarily as ferrous Fe. Ferric Fe is absorbed in proportion to the degree to which it is reduced in the intestine or by virtue of simultaneously ingested reducing agents such as vitamin C. Differences of gastric acidity are relatively unimportant because of the high acidity of the Fe salts themselves. Insol. ferrous and ferric phosphates caused no increase in serum Fe. The height or character of the serum-Fe curve was not affected by bile pigment, chlorophyll, secondary anemia fraction and gastric mucin. On the basis of this work and that reported in the literature a picture of Fe absorption is presented. J. B. Brown

Species specificity of the gonadotropic factors in vertebrates. Charles W. Creaser and Aubrey Gorbman. *Quart. Rev. Biol.* **14**, 311–31(1939).—As a result of expts. on the leopard frog with various gonadotropic materials and a review of the literature it is concluded that a qual. species variation exists in gonadotropic hormones. J. B. Brown

The water balance in marine mammals. E. S. Fetcher, Jr. *Quart. Rev. Biol.* **14**, 451–9(1939).—A review. The blood f. p. depression of marine mammals is about 0.69°. Whole blood Na, Ca and Cl are somewhat higher than in land mammals. Urine total salt concns. are 16–82 g./l. Urea concns. are normal. Marine mammals living on invertebrates probably have a special mechanism for reduction of urinary salt concn. J. B. Brown

The effect of obstetrical anesthesia upon the oxygenation of maternal and fetal blood with particular reference to cyclopropane. Clement A. Smith. *Surg. Gynecol. Obstet.* **69**, 584–93(1939).—The O content of the arterial and venous blood of women in labor was detd., also of 3 groups of mothers and their infants at the time of birth. Fetal blood at the time of birth showed wide variations in O content, but as a rule there tended to be an anoxemia even on the arterial side. Ether anesthesia elevated the O of the maternal blood. Nitrous oxide produced anoxemia in both maternal and fetal bloods. Cyclopropane definitely raised the maternal and fetal O, but the latter was lower than with ether. Cyclopropane was present in maternal and fetal bloods in about equal amts. J. B. Brown

The action of some androgenic substances on the immature female rat and guinea pig. J. R. Groome. *Quart. J. Exptl. Physiol.* **29**, 367–77(1939).—Six immature female rats injected with 500 γ testosterone proprionate daily for 8 days showed on the 9th day an abnormal increase in body wt. not due to fat deposits, abnormal presence of graafian follicles and in 4 cases of corpora lutea in the ovary, hypertrophy of the uterus, of the preputial glands and of the clitoris-like organ, mucification of the vaginal epithelium and no mammary development with one exception. Solid testosterone implantations, of which 15 mg. were absorbed in 30 days by 2 oöphorectomized immature guinea pigs, were assocd. with an increase in body wt. without fat deposits, and with hypertrophy of the uterus and clitoris and the formation of horny styles on the latter. A successful testicular graft was made in one guinea pig which received 200 rat units of gonadotropic hormone in 10 days. After 30 days there was uterine hypertrophy but no increase in body wt. or in the length of the clitoris. Rachel Brown

Secretion and "formation" of adrenaline in isolated adrenal glands. V. O. Osinskaya. *Méd. exptl.* (Ukraine) **1939**, No. 4, 24–31.—Expts. were performed on 50 pairs of isolated adrenal beef glands, one of the pairs always serving as a control. The total adrenaline content of the left gland was usually greater than that of the right gland, though the concn. per g. of tissue was approx. the same in both glands. Perfusion of the isolated gland with

Ringer-Locke soln. led to an increase in the total adrenaline content of the gland as compared with the corresponding nonperfused gland. Acidification of the Ringer-Locke soln. with AcOH or HCl to a pH of 4.5 had no effect on the total adrenaline content but increased markedly the rate of extn. of adrenaline by the perfusate. Alk. Ringer-Locke soln. (pH of 9.0–10.0) produced some increase in the rate of extn. and in the total adrenaline content of the perfused gland. S. A. Corson 1

Glycogen content, reducing substances and intensity of glycogenolysis in different organs. O. V. Fastyuchenko. *Méd. exptl.* (Ukraine) **1939**, No. 4, 32–7.—Glycogen (Simonovich and Kochnevaya modification of Pflüger's method) and reducing substances (Urbach's modification of Hagedorn-Jensen's method) were detd. in the tissues of the pancreas, thyroid, adrenal, kidney, spleen, salivary glands and lungs. True sugar (Raymond and Blanco modification (cf. *C. A.* **23**, 173) of Somogyi's method) was detd. in the pancreas. The marked decrease in the glycogen content of the isolated tissues (kept for 30 min.–2 hrs. at 18, 22 and 37°) was not accompanied by any significant increase in reducing substances. This is explained by lactic acid formation. True sugar in the pancreas amounts to 50–70% of the total reducing substances. S. A. Corson 2

Quantitative chemical study of the urinary excretion of thiamine by normal individuals. Daniel Melnick, Henry Field, Jr., and Wm. D. Robinson. *J. Nutrition* **18**, 593–610(1939); cf. *C. A.* **33**, 2162[6], 8636[3].—The reaction between thiamine and diazotized *p*-aminoacetophenone in alk. soln. was used for the chem. detn. of thiamine in urine. There is a diurnal variation in the amt. excreted due to an appreciable lag in excretion following meals. The av. 24-hr. urinary thiamine values of 15 men and 9 women were 198 and 93 γ, resp.; 14% of the oral dose of 5 mg. of extra vitamin were excreted by the men during the first 24-hr. period following ingestion and 12% by the women. The percentage of the available vitamin, which is excreted in the urine, is a function of how great an excess is present. Standards are given for the interpretation of the urinary thiamine values in the diagnosis of thiamine deficiency. 24 references. C. R. Fellers 4 5

The chemistry of egg formation. R. M. Conrad. *Kansas Agr. Expt. Sta., 9th Biennial Rept.* **1938**, 96; cf. *C. A.* **32**, 3803[5]; **33**, 7861[1].—A summary of investigations at the Kan. Agr. Expt. Sta. C. R. Fellers 6

Hydrogen-ion concentration of the fluid content of the alimentary canal of the horse. J. H. Whitlock, E. E. Leasure, C. H. Kitselman, C. C. Morrill and W. W. Thompson. *Kansas Agr. Expt. Sta., 9th Biennial Rept.* **1938**, 111.—A quinhydrone pH indicator was used to det. the H-ion concn. of fluid samples from the alimentary canal of the horse. The detns. were made within 14 min. after the death of the horse. The values are as follows: stomach 0–7.63; duodenum 6.48–8.04; jejunum 6.87–7.97; ileum 7.35–7.89; cecum 6.02–7.79; large colon 6.15–8.00; rectum 5.39–7.13. C. R. Fellers 7

Metallic elements and blood formation. M. O. Schultze. *Physiol. Reaction of the hypophysis to arterial hypertension of central origin. Gonadotropic hormones. Adalbert van Bogaert and F. van Baarle. *Compt. rend. soc. biol.* **132**, 335–40(1939).—In dogs exptl. hypertension of central origin sometimes causes the appearance of hypophyseal gonadotropic hormone in the spinal fluid. No folliculin appears in the urine. L. E. Gilson

Variations in plasma potassium after bleeding and transfusion. J. L. Moglia. *Compt. rend. soc. biol.* **132**, 513–14(1939).—See *C. A.* **33**, 8741[3]. L. E. Gilson

Adrenalectomy and the cyclic vaginal response to estrone. G. Di Paola. *Compt. rend. soc. biol.* **132**, 517–18(1939).—See *C. A.* **33**, 8741[4]. L. E. Gilson

Effect of adrenocorticotropic hormone in four-day-old rats. Henry D. Moon. *Proc. Soc. Exptl. Biol. Med.* **43**, 42–4(1940).—Rats 4 days old are a more sensitive test animal for the hormone than rats 21–23 days old. L. E. Gilson

Effect of adrenocorticotropic hormone on the thymus of rats. Robert H. Crede and Henry D. Moon. *Proc. Soc. Exptl. Biol. Med.* **43**, 44–6(1940); cf. *C. A.* **32**, 5460[4].—Pituitary adrenocorticotropic hormone caused acute thymic atrophy in normal rats 21–23 days old but not in adrenalectomized rats. Castration did not prevent this thymic atrophy, hypophysectomy decreased it a little. L. E. Gilson 3

Response of thyroidectomized rats to adrenocorticotropic hormone. Henry D. Moon and Wayne Hansen. *Proc. Soc. Exptl. Biol. Med.* **43**, 46–8(1940).—The adrenal hypertrophy of both normal and thyroidectomized male rats 22 days old was directly proportional to the amt. of the hormone injected. Feeding desiccated thyroid to the normal rats did not modify the effect. L. E. Gilson

Vaginal cycle of Microtus guentheri and its response to estrogenic and gonadotropic hormones. Bernhard Zondek and Felix Sulman. *Proc. Soc. Exptl. Biol. Med.* **43**, 86–8(1940).—In *Microtus guentheri*, of the Muridae, a crop-destroying rodent of Palestine, no vaginal cycle with a cornification stage occurs as in white mice and rats, but injections of very large doses of estrogenic hormone induce cornification. Gonadotropic hormone from pregnancy urine has no effect, that from mare serum induces follicle maturation without luteinization, and that from animal hypophysis produces both follicle maturation and corpus luteum formation, hence the animal may be used to test gonadotropic hormones and det. their origin. L. E. Gilson

Conversion of *S*-benzylglutathione to benzylmercapturic acid in the rat. Jacob A. Stekol. *Proc. Soc. Exptl. Biol. Med.* **43**, 108–10(1940); cf. *C. A.* **33**, 4300[8].—The prepn. of *S*-benzylglutathione is described. When 0.5 g. was fed to a rat *N*-acetyl-*S*-benzyl-*l*-cysteine was found in the urine. This shows that the peptide was hydrolyzed and the *S*-benzylcysteine then acetylated. L. E. Gilson

Diminution of the acetylcholine content of the retina after prolonged functional disuse. Hsi-Chun Chang, Wei-Ming Hsieh, Lao-Ying Lee and Tsung-Han Li. *Proc. Soc. Exptl. Biol. Med.* **43**, 140(1940).—In dogs, keeping the lids of one eye sewn shut for 170 days decreased the acetylcholine of the retina to less than half the normal content. The eyes were not otherwise affected. L. E. Gilson

Attempt to modify growth, development and tumor incidence in mice with thymus extracts. George van S. Smith and E. Elizabeth Jones. *Proc. Soc. Exptl. Biol. Med.* **43**, 157–60(1940).—Repeated injections of calf thymus ext. had no effect on growth or development of albino mice. A marked lowering of fertility occurred in the 2nd and 3rd generations. This resulted in survival of too few females to tumor-susceptible age to permit any conclusions as to effect on incidence of spontaneous tumors. Injections of *p*-thiocresol continued for 5 generations had no effect on the fertility, growth or development of the same strain of mice, or on the incidence of spontaneous tumors or growth of inoculated tumors. L. E. Gilson

Hormonal inhibition of lactation. R. P. Reece, J. W. Bartlett, I. L. Hathaway and H. P. Davis. *Proc. Soc. Exptl. Biol. Med.* **43**, 183–6(1940); cf. *C. A.* **33**, 7862[9].—The effectiveness of pituitary estrogens in inhibiting lactation in the rat can be increased by simultaneous administration of gonadotropic principle from human pregnancy

urine. Many cells in mitoses are seen in the mammary parenchyma of rats so treated. L. E. Gilson

New problems in the physiology of work. IV. Carbon monoxide. O. Ehrismann. *Deut. med. Wochschr.* **65**, 1522–5(1939).—A review with 21 references. A. G.

Chemical determinations of certain constituents of blood of nonlactating Red Scindi cows. Arcadio C. Gonzaga. *Philippine J. Animal Ind.* **6**, 253–6(1939).—Examn. of blood from 15 cows gave values for constituents per 100 cc. blood as follows: blood sugar 39.43, total nonprotein N 20.43, urea N 10.51, serum Ca 9.93, inorg. phosphate 6.72, chlorides as NaCl 485.67 and Fe 42.05 mg.; hemoglobin 12.55 g. and O_2 16.82 cc. J. O. Hardesty

The present status of the blood-coagulation problem. Harry Eagle. *Symposium on the Blood and Blood-Forming Organs, Univ. Wisconsin* **1939**, 242–64. E. H.

The presence of vasoconstrictor substances in the blood of dogs rendered hypertensive by section of the vasomotor nerves. Henri Hermann, F. Jourdan and A. Delrieu. *Arch. maladies coeur vaisseaux* **32**, 545–55, 631(1939).—Marked and lasting hypertension is produced in dogs by section of the vasomotor innervation of the aorta and carotid sinus. This effect is not abolished by removal of the adrenal glands, and hence is not dependent on production of adrenaline by these glands. Sympathin is believed to be the substance responsible for the hypertension. Marion Horn

The oxidase reaction of normal and tumor tissues. E. E. Faerber. *S. African J. Med. Sci.* **4**, No. 1–2, 1–6 (1939).—A preliminary expt. indicated that ether, unlike some other narcotics, does not paralyze the cellular dehydrogenase. The brain gray matter, the heart and the skeletal muscle of the mouse give strongly pos. oxidase reactions. The brain white matter, the nerve and the spleen give either neg. or feebly pos. oxidase reactions. The reaction of the spleen may account for certain peculiar respiratory phenomena. A rapidly growing mouse sarcoma gave a neg. or very slightly pos. oxidase reaction. Fourteen references are given. W. R. Henn

Studies on the erythrocytes, hemoglobin and iron content of the blood of normal subjects at the altitude of the Witwatersrand (6000 feet). P. H. Symons. *S. African J. Med. Sci.* **4**, No. 1–2, 18–30(1939).—The subjects of the investigation were healthy adult lab. workers and medical students acclimated by a min. residence of several months at this altitude. The results of the Haldane carboxyhemoglobin method agreed closely with those of the Fe-detn. method for hemoglobin as modified by S. The following mean values are suggested as being normal for the altitude of Witwatersrand for adult males and females, resp.: hemoglobin (in percentage on Haldane scale) 106.9 and 102.0, erythrocytes (in millions per cu. mm.) 6.02 and 5.44 and color index 0.89 and 0.94. A comparison of the results of this investigation shows that from an increase of the altitude of nearly 6000 feet (1) the hemoglobin content is not significantly altered, (2) the erythrocyte count is significantly increased, and (3) the color index is significantly decreased. The results of cell vol. detns. show that the erythrocytes present no marked tendency toward microcystosis; they are apparently normocytic and slightly hypochromic. The mean erythrocyte count of normal adult females at an altitude of 6000 feet is approx. 0.6 million less than that of normal adult males at the same altitude. Nineteen references are given. W. R. Henn

The correlation of physicochemical properties of serum with its effect on the growth of tissues in vitro. II. The effect of diluting serum on its buffering power. W. S. S. Ladell. *S. African J. Med. Sci.* 4, No. 3, 61–76(1939); cf. *C. A.* **34**, 1720[7].—Different concns. of horse serum in Tyrode soln. were titrated with CO_2 in an app. designed for this purpose, the pH being measured by means of the quinhydrone electrode. The expts. were controlled by blank titrations and by titrating in the same way as the mixts. a soln. of $NaHCO_3$ contg. base equiv. to that in blood. The results obtained for undild. serum and the $NaHCO_3$ were found to agree with those obtained by other investigators on the acid-base equil. in blood. The effect of dilg. serum with saline gives results similar to those recorded for decreasing alkali reserve of the plasma, and the buffering power of serum is much decreased on diln. The prolonged exposure to air of various serum-saline mixts. caused the undild. serum to become more alk., while the highly dild. mixts. became more acid. In the former there is a loss of CO_2, while in the latter CO_2 is absorbed in spite of its low tension in atm. air (due to the salts of the alk. earths in the Tyrode). The poor growth of tissues *in vitro* (noted in low and high concns. of serum, resp.) might be explained in part by the poor buffering power of the mixt. acting in conjunction with the growth-inhibiting factor (in the first instance) and by good buffering power at a pH too alk. for optimal growth (in the 2nd instance). The good growth at medium concns. of the serum is attributed to the relatively good buffering power of the mixt. near the optimal pH and to the fact that such a soln. is apparently able to absorb CO_2 at very low tension; these counteract the growth-inhibiting factors in the serum. Four graphs, 2 tables and 18 references are given. W. R. Henn

Sheep-sterility investigations. W. M. Webster. *New Zealand Dept. Sci. Ind. Research, Ann. Rept.* **13**, 45–6 (1939).—Acid samples of seminal fluid were fertile with few exceptions and, within certain limits, the fertility increased with increasing acidity. No samples having pH values greater than 7.0 were fertile when tested by artificial insemination. With semen showing initial pH values of 6.5–7.5, storage for 0.5 hr. under oil at atm. temp. caused the pH to decrease to 5.5–6.0. The change was most rapid on warm days, but slowed up considerably after the 1st 0.5 hr. When the semen showed initial pH values of 7.5–8.0 a relatively slight decrease in pH occurred during the 1st 0.5 hr. of storage under oil. The seminal plasma has a high content of glucose and the acid drift is assocd. with oxidation of the glucose to lactic acid. The extent of the drift depends on the no. of spermatozoa in the semen and their activity. K. D. Jacob

The effect of picric and flavianic acids on the potency of the follicle-stimulating anterior pituitary hormone. H. Jensen and Sibylle Tolksdorf. *J. Biol. Chem.* **132**, 519–26(1940).—The effect of picric and flavianic acids on the potency of hypophyseal follicle-stimulating prepns. has been studied and the claim of Fevold (*C. A.* **33**, 3857[5]) that this hormone is reversibly inactivated by these acids could not be substantiated. The apparent reactivation which Fevold observed is interpreted as being due to the addn. of tannic acid which causes the hormone to manifest itself more markedly and not to removal of the picric or flavianic acids. Although there is undoubtedly a chem. difference between the follicle-stimulating and the luteinizing hormones of the pituitary, it cannot be based on a difference in reaction with picric, picrolonic or flavianic acids. A. P. Lothrop

The formation of creatine from glycocyamine in the liver. Henry Borsook and Jacob W. Dubnoff. *J. Biol. Chem.* **132**, 559–74(1940); cf. *C. A.* **34**, 2012[8]. —Liver slices of the cat, rabbit and rat convert glycocyamine into creatine, the increase being 5–20 times the amt. originally present in the slices. When methionine is present in Ringer soln., the amt. of creatine formed by rat liver was on the av. about 50% greater than in its absence. No other substance among 34 compds. tested, including amino acids, methylated amines and betaine, effected this methylation in rat liver. It seems reasonable to conclude that rat liver slices transfer the Me group of methionine to glycocyamine, thus converting it into creatine. A. P. Lothrop

Relative amount of hepatic glycogen deposited by glucose, glycine and *dl*-alanine. Eaton M. MacKay, Arne N. Wick and Herbert O. Carne. *J. Biol. Chem.* **132**, 613–17(1940).—When equiv. amts. of glucose, glycine and *dl*-alanine are fed to rats, the amt. of glycogen deposited in the livers is approx. the same, the max. hepatic glycogen concns. being 2.00, 2.36 and 1.96%, resp. The rate of glycogen deposition, on the other hand, is very different, the peak of glycogen formation occurring in 6, 10 and 14 hrs., after feeding glucose, *dl*-

alanine and glycine, resp. These findings cannot be interpreted on the basis of differences in the rate of absorption from the intestine. It is easy to see from these data the reason for diverse conclusions reached in regard to the glycogen-forming efficiency of compds. when observations are made at a single point. A. P. Lothrop

Water and electrolyte content of normal and hydronephrotic kidneys. Lillian Eichelberger and Walter G. Bibler. *J. Biol. Chem.* **132**, 645–56(1940); cf. *C. A.* **33**, 2189.—The mean values for the total water and electrolyte concns. in kidneys from normal dogs were: total water 802.2 ± 5.0 g.; chloride 67.7 ± 5.3; Na 82.6 ± 5.8; K 58.3 ± 4.0; Ca 2.16 ± 0.53; Mg 5.7 ± 0.5 millimols. per kg. of fat-free tissue. The values for water, fat, Na and Cl were always more for the roughly dissected medulla than for the cortex, indicating the necessity of analyzing whole kidneys since the distribution of water and electrolytes differs so distinctly in the medulla and cortex and since the 2 zones are distributed in different ratios in different portions of the kidney so that an exact dissection cannot be made. In hydronephrotic kidneys there was a significant increase in total water content but no change in Na, K or Mg concns. There was a decrease in Cl and an increase in Ca which, however, were of doubtful statistical significance. A. P. Lothrop

Studies in histochemistry. XV. The histological distribution of cholinesterase in the adrenal gland. Wm. Antopol and David Glick. *J. Biol. Chem.* **132**, 669–73(1940); cf. *C. A.* **31**, 43663.—The cortical region of the adrenal gland possesses little cholinesterase activity, but the medulla is relatively potent. Pig, beef and rabbit adrenals were examd. and no species differences were found. No variations were observed in the enzyme activities of the cell types in the cortex. A. P. Lothrop

Comparative studies on creatine, phosphorus and potassium in various tissues. Victor C. Myers and Geo. H. Mangun. *J. Biol. Chem.* **132**, 701–9(1940); cf. *C. A.* **7**, 1221.—The correlation between creatine and total acid-sol. P is approx. the same in brain and in widely differing muscles from the rabbit, dog and human being. Change in creatine concn. is assocd. with a variation in K in the approx. ratio of 1 mole of creatine to 2 moles of K, thus supporting the hypothesis that phosphocreatine is present in the form of the di-K salt. A. P. Lothrop

The utilization of acetone bodies. III. The influence of adrenalectomy. Norton Nelson, Isabelle Grayman and I. Arthur Mirsky. *J. Biol. Chem.* **132**, 711–15(1940); cf. *C. A.* **33**, 1466.—The general decrease in metabolic activity consequent to adrenalectomy is likely responsible for the marked reduction in the rate of acetone body utilization which was observed. It is probable that a similar reduction in the rate of their formation also occurs in spite of the fact that the adrenals *per se* are not essential for this process. A. P. Lothrop

The relation of the follicle-stimulating activity of fresh pituitary tissue to the action of the enzymes contained in the tissue. W. H. McShan and Roland K. Meyer. *J. Biol. Chem.* **132**, 783–4(1940); cf. *C. A.* **33**, 7121.—The proteolytic enzyme (probably cathepsin) of fresh pituitary tissue inactivates the luteinizing hormone without the destruction of the follicle-stimulating activity. Impurities can be removed from the clear centrifuged water ext. of the pituitaries by pptn. with Me_2CO, and the follicle-stimulating material which remains in the Me_2CO soln. can be recovered assocd. with relatively little solid matter. It may be possible to use this inexpensive and simple procedure in the prepn. of follicle-stimulating material of low solid content for the study of the chemistry of this hormone. A. P. Lothrop

The composition of unsaponifiable lipides. Heinrich Waelsch and Warren M. Sperry. *J. Biol. Chem.* **132**, 787–8(1940).—The D content of the unsaponifiable lipides isolated from the carcass (less brain, liver and intestinal tract) of rats in which the body water had been enriched with D for 4–7 days was surprisingly high, exceeding in most rats that found in brain, liver or intestine. They were sepd. into cholesterol, alcohol, keto and hydrocarbon fractions. The findings emphasized are (1) the proximity of D concns. in the cholesterol, keto and hydrocarbon fractions, suggesting a close metabolic relation among them and (2) the high D content of the alc. fraction which contained approx. twice as much D as the other unsaponifiable fractions and more, with few exceptions, than any fat acid fraction isolated from any tissue during this work. The latter finding suggests that the compds. comprising the alc. fraction are intermediates in the synthesis of fat acids. An alternate interpretation would be that they are formed in the dismutation of aldehydes (plasmal) *in vivo* or *in vitro* during alk. hydrolysis. The investigation of the unsaponifiable fraction with D as an indicator is being continued with particular attention to the possible role of aldehydes in its genesis and in the synthesis of fat acids. A. P. Lothrop

Inhibition of isohemoagglutination of blood plasma. Kitiro Kurokawa. *Tohoku J. Exptl. Med.* **36**, 523–41 (1939).—Blood anticoagulants like Na citrate and NaF exert no influence on the isohemoagglutination in the amts. usually employed. Dextrose used for the purpose of diln. or handling the erythrocytes of the serum causes a lowering of the agglutination titer $^2/_3$ that of a NaCl soln. The amt. of cholesterol, lecithin or euglobulin in the erythrocytes or in the serum has no correlation with the agglutination titer, but the titer of different group sera toward the same erythrocytes runs parallel with the lipoid content, but not in a strict math. sense. B. Prescott

The influence of intravenous oxygen injections on respiration and the intermediary carbohydrate metabolism by breathing oxygen-poor or carbon dioxide-saturated air. Tetusaburo Isikawa. *Tohoku J. Exptl. Med.* **36**, 542–60 (1939).—Dogs were injected intravenously with O, 0.3 cc. per kg.; 3 injections were given with a 15-min. interval between each injection. The blood CO_2 showed no changes but the O consumption showed a decrease. Lactic acid showed a tendency to decrease slightly with the blood sugar unaffected. When a gaseous mixt. with a 10% reduction in O is inhaled, there is an increase in respiration, a decrease in blood CO_2, a decrease in O consumption, and an increase in blood lactic acid and blood sugar. If under these conditions O injections are given, the blood CO_2 decreases, O consumption decreases, blood lactic acid increases and blood sugar decreases. Breathing a gaseous mixt. which has 12.2–15.4% CO_2 caused an increase and larger respiratory movements as well as an increase in the pulse rate. O consumption increased in small amts. with a decrease in lactic acid and a slight increase in blood sugar. Benjamin Prescott

Changes in blood albumin and osmotic pressure of its colloids on rapidly alternating diminution and restoration of atmospheric pressure. Tetusaburo Isikawa. *Tohoku J. Exptl. Med.* **36**, 561–82(1939).—Diminishing the atm. pressure and then raising it causes an increase in serum albumin, with a rise in hemoglobin (Hb) concn. The increase in both blood components is not due solely to a blood concn., since the colloidal osmotic pressure changes are not the only conditions to be dealt with, because in using higher pressure the serum albumin increases much faster than the Hb concn. Repeating the decompression and pressure reduction 3 times in dogs shows the following picture in the arterial blood: The Hb and serum albumin show slight increases. There appears to be a tendency toward a decrease. The decrease in albumin is larger than the Hb concn. The assumption is that under these conditions the capillaries become permeable to the proteins in the blood, especially the osmoactive albumin fraction, whereas on the other hand the mobilization of the albumin fraction from the protein depot organs takes place more intensively as the diminished pressure becomes increased. Benjamin Prescott

Peroxidase reaction. CXX. Arakawa's reaction and vitamin C content of human milk. 4. Is the amount of vitamin C in Arakawa-positive milk not sufficient for a growing infant? Siroku Isono. *Tohoku J. Exptl. Med.* **37**, 33–44(1939); cf. *C. A.* **34**, 20092.—The more intense the negativity of Arakawa's reaction of human milk, the greater is the content of vitamin C (-like substance) in general. Human milk pos. to Arakawa's

reaction seems to furnish a sufficient amt. of vitamin C for a growing baby clinically. An infant fed on human milk with a low titration value by the 2,6-dichlorophenolindophenol method is free from scurvy. If the vitamin C-like substance in Arakawa-neg. milk is vitamin C itself, then that milk contains more than a necessary amt. of vitamin C. Benjamin Prescott

Peroxidase reaction. CXXI. Blood platelet count of sucklings according to Arakawa reactions of their mothers. Masayuki Sindo. *Tohoku J. Exptl. Med.* **37**, 45–61 (1939).—Infants of mothers whose milk gave a neg. Arakawa reaction showed increased blood platelet count (435,000 thrombocytes per cu. mm.), of those with an intermediate reaction a count of 384,000 and of those mothers with a normal Arakawa-pos. reaction a count of 301,000. A slight anemia occurred in the Arakawa-neg. group while all others were normal. Vitamin B prepns. given to infants or mothers moderately increased the blood platelet count in the Arakawa-neg. group. Infants and mothers not given vitamin B prepns. showed normal platelet counts in the Arakawa-pos. group, but an increase in those with an intermediate reaction and a maximal av. count of 458,000 in the neg. group. A close relation exists between blood platelet counts of infants and the Arakawa reactions of their mothers. M. M. R.

Peroxidase reaction. CXXII. Arakawa's reaction and content of methylglyoxal-like substance of human milk. Siu Sato. *Tohoku J. Exptl. Med.* **37**, 62–77(1939).—The methylglyoxal-like substance of human milk is poor in Arakawa-pos. milk and rich in Arakawa-neg. milk. Avitaminotic diseases of all kinds, namely beriberi, infantile preberiberi, B-avitaminotic dyspepsia, rickets, anemia and hereditary syphilis had a large amt. of the methylglyoxal-like substance in the mother's milk, but grippe and dyspepsia (except avitaminotic dyspepsia) had a relatively small amt. One case of pertussis had a large amt. of the substance in the mother's milk. Seasonal variations were observed in this study. B. Prescott

Changes in the intermediate carbohydrate metabolism and serum albumin in respiration at increased atmospheric pressure. Tetusaburo Isikawa. *Tohoku J. Exptl. Med.* **37**, 1–32(1939).—Rabbits were exposed to pressures of 60, 85 and 130 lb. in a pressure chamber and variations in lactic acid, sugar, hemoglobin, albumin and colloid-osmotic pressure of the blood noted immediately after the pressure was removed. Lactic acid, hemoglobin content, albumin and colloid-osmotic pressure diminished. Blood sugar increased, the increase being greater with greater pressure and duration of the stay in the chamber. Maurice M. Rath

Effect of sodium bicarbonate upon oxygen consumption of the rabbit retina in vitro. Norio Oyama. *Tohoku J. Exptl. Med.* **37**, 78–87(1939).—As detd. by Warburg's method (cf. *C. A.* **18**, 2036), within a pH range 6.88–7.88 the O consumption of rabbit retina in Ringer soln. at 38° increased with increasing alky. Within the range in $NaHCO_3$ concn. $1.2 \times 10^{-3} - 3.4 \times 10^{-2}$ *M*, O consumption increased with increasing concn. The changes in O consumption were closely related to the H-ion concn. and buffering capacity of the medium. $NaHCO_3$ is an excellent agent to maintain O consumption of the retina const. for long periods of time. The $NaHCO_3$ concn. and the atm. of soln. in the respiratory vessel play an important role. With 1 cc. of the $NaHCO_3$-Ringer soln. (3.4×10^{-2} mols.) respiration remained const., but with lower concns., the medium became gradually acid and finally a temporary decrease in respiration occurred. M. M. R.

Chemistry of the human skin. IV. The electrokinetic effect of various ions on suspended particles of stratum corneum. Vernon A. Wilkerson. *J. Gen. Physiol.* **23**, 165–70(1939); cf. *C. A.* **33**, 7866⁸.—The electrokinetic p. d. of skin particles in salt solns. is ultimately decreased if sufficient salt is added. The inhibitory effect of cations decreases in the order: Al, Ca, Ba, K, Na. Alkali halides with common neg. ions affect the electrokinetic p. d. in the order: Li > Na > K > Rb; the same order is given by such inert interfaces as cellulose and glass. Similar salts with common pos. ions give the series: Cl > I > Br, whereas passive surfaces give the order: I > Br > Cl. Evidently skin selectively absorbs Cl; this theory coincides with the known high Cl concn. of skin (Lepore and McCoord, *C. A.* **27**, 2198). The greatest rate of flow under the force of an elec. current would be given by concns. of neutral salts of 0.0001 *M* to 0.0002 *M*. C. H. Richardson

Oral use of pregneninonol in functional menometrorrhagia. E. C. Hamblen, N. B. Powell, W. Kenneth Cuyler and C. J. Pattee. *Endocrinology* **26**, 201–7(1940).—Oral therapy (estradiol followed by estriol glucuronide and pregneninonol) was given cyclicly to 7 young women with functional meno-metrorrhagia. Patients tolerated well the oral administration of as much as 160 mg. of pregneninonol daily for 14 days each month for several months. Bleeding of cyclic character and normal amt. occurred during treatment. There was an increase in pro-gestational response. The therapy produced no significant alterations in the urinary titers of Na pregnanediol glucuronide and androgens. Felix Saunders

Inhibition of lactation post partum with testosterone propionate. Jacob S. Beilly and Samuel Solomon. *Endocrinology* **26**, 236–40(1940).—The therapeutic rationale of testosterone propionate in inhibition of lactation post partum is discussed. Felix Saunders

Mode of action of testosterone propionate on the female genital tract. John W. Huffman and Louis H. Bos. *Endocrinology* **26**, 259–63(1940).—Testosterone propionate inhibits functional uterine bleeding and menstruation. Pregnant mare serum ext. produces the same responses in the rabbit ovary either before or after prolonged administration of testosterone propionate. The inhibition by testosterone propionate of cyclic changes in the female genital tract is not due to a direct action on the ovary but rather to pituitary inhibition. Felix Saunders

Obesity in the rat following the injection of chromic acid into the hypophysis. Albert W. Hetherington. *Endocrinology* **26**, 264–8(1940).—Chromic acid was injected into the hypophyses of rats *via* a parapharyngeal approach. Only 3 of 51 animals operated showed any resultant adiposity. Analysis showed that these animals contained up to 50% more fat than their litter-mate controls. All were somewhat dwarfed. Histological examn. revealed extensive damage to the hypothalami and hypophyses of the fat rats. In neg. cases hypothalamic injury was slight or absent, although hypophyseal injury was often severe. No obese cases with intact hypophyses were discovered. Felix Saunders

Androgenic action of desoxycorticosterone. Charles W. Hooker and Vincent J. Collins. *Endocrinology* **26**, 269–72(1940).—Daily injections of 2 mg. of desoxycorticosterone acetate into capons for 5 days resulted in an av. increase of slightly more than 3 mm. in the length plus height of the combs. Daily injections of 1 mg. into castrated rats maintained the wt. of the prostate and seminal vesicles but did not prevent castration changes in the histology of these organs. Administration of 0.5 and 0.25 mg. to mice gave results essentially similar to those obtained with rats. The androgenic activity of the compd. is approx. $^1/_{30}$ as great as that of androsterone. The compd. resembles androsterone more than testosterone in being relatively more active upon the comb than upon the rodent accessories. Felix Saunders

Experiments on the biological properties of stilbestrol and stilbestryl dipropionate. C. H. Mellish, A. J. Baer and A. C. Macias. *Endocrinology* **26**, 273–9(1940).—Stilbestrol and stilbestryl dipropionate are at least as effective as an equal wt. of estrone in producing growth and development of the immature rabbit uterus and sensitizing it to progesterone. Neither deriv. showed progestin-like action when administered to immature female rabbits in doses of 1.0 and 4.0 mg., resp., over a period of 10 days. Subcutaneous implants of 10 mg. of both compds. were made in 30-day-old rats. The animals were autopsied at 56–8 days of age. Stilbestrol inhibited body growth in both sexes. In males the dipropionate showed a more effective inhibition of body growth and a more prolonged action than did stilbestrol. Both compds.

inhibited the growth of gonads of both sexes. Stilbestrol markedly reduced the gonadotropic potency of the anterior pituitary of the female but showed relatively little inhibitory action on the male hypophysis. Stilbestryl dipropionate reduced the gonad-stimulating power of the male pituitary. Chorionic gonadotropin increased the ovarian wt. of rats previously treated with stilbestrol. The wt. increment was equal to that produced by human pregnancy urine ext. in untreated animals of the same age but less than that resulting from its administration to immature animals. The derivs. increase the wt. of the pituitary but do not change the wt. of the adrenals. Felix Saunders

Influence of estriol, estradiol and progesterone on the secretion of gonadotropic hormones in parabiotic rats. Clyde Biddulph, Roland K. Meyer and Laurence G. Gumbreck. *Endocrinology* **26**, 280–4(1940).—In 31–41-day-old female-female pairs 0.025 γ of estradiol, 1.5 γ of estriol and 1 mg. of progesterone per day are required to prevent the hypersecretion of gonadotropic hormone that occurs after castration of the female rat. In female-male pairs 0.15 γ of estradiol and 10 γ of estriol per day are necessary to prevent hypersecretion in the male. The order of effectiveness of the estrogens in preventing castration hypersecretion, i. e., estradiol > estrone > estriol, is the same as the order of their effectiveness in producing vaginal cornification. Felix Saunders

Glycogen breakdown and synthesis in animal tissues. Carl F. Cori. *Endocrinology* **26**, 285–96(1940).—A discussion of the enzymes concerned with the breakdown and synthesis of glycogen and their interaction with various hormones. Felix Saunders

Characteristics for the transport of oxygen by the blood of mink and marten. Walter J. Scott, Laurence Irving and Virginia Safford. *J. Cellular Comp. Physiol.* **14**, 281–6(1939).—Oxygen dissocn. curves for the blood of mink (*Mustela vison*) and marten (*Martes americana*) resemble the curves for the blood of other mammals. At pCO_2 40 mm., the pressure for half satn. of the hemoglobin is 37 for mink, 38 for marten blood. The O capacity of mink blood is 23.9 cc. per 100 cc. of blood; for marten blood it is 24.3 cc. Felix Saunders

Effect of hypertonic and hypotonic solutions on the respiration of chicken erythrocytes. F. R. Hunter. *J. Cellular Comp. Physiol.* **14**, 412–14(1939).—The rate of O consumption of chicken erythrocytes placed in a hypertonic environment is irreversibly decreased. Hypotonic environments have little or no effect until a large part of the cells are hemolyzed. Felix Saunders

Urinary output of creatine and creatinine associated with physical exercise, and its relation to carbohydrate metabolism. W. Hobson. *Biochem. J.* **33**, 1425–31(1939).—The excretion of creatine and creatinine in 97 male students resident in a physical-training college was studied. The subjects showed a higher creatinine-N coeff. than the accepted "normal" value. Although creatinuria is usually not found in adult males, it occurred in 96 of the subjects, the range for 24 hrs. excretion being 92 to 1200 mg. with a mean of 637. No correlation was detected between increasing physical fitness and the magnitude of the creatine or creatinine excretion. Subjects placed on a low-carbohydrate diet showed a disclination to undertake muscular work and fatigue ensued more rapidly than usual. Under these conditions creatinuria diminished or disappeared. E. W. Scott

Diffusing factors. III. Juan Madinaveitia. *Biochem. J.* **33**, 1470–7(1939); cf. *C. A.* **33**, 6934[3].—Crude rattlesnake venom contained a diffusing factor similar to that obtained from testes, accompanied by another factor which caused a slow spread of indicators through the skin. Cryst. crotoxin contained only the second factor. Although the crude venom and filtrates from *Cl. welchii* have proteolytic activity, it is unlikely that this is assocd. with the diffusing factor, since testicular exts. have no such activity. The diffusing factors from testicle and *Cl. welchii* were strongly adsorbed by alumina Cγ from which they were eluted with Na_2CO_3 or Na_2HPO_4. The similar behavior of the factors from these sources suggested that they were the same or closely related proteins. E. W. Scott

Acetylcholine metabolism in the central nervous system. P. J. G. Mann, M. Tennenbaum and J. H. Quastel. *Biochem. J.* **33**, 1506–18(1939); cf. *C. A.* **33**, 8271[4].—Glucose (I) at low concns. (below 20 mg./100 g.) brought about the synthesis of acetylcholine (II) in intact brain slices (rat). Fructose and galactose had only slight effects in the synthesis, but mannose had an activity near that of I. The failure of Stedman and Stedman (*C. A.* **33**, 8271[1]) to confirm this effect of I was shown to be due to limitations of their technique. Preformed "bound" II was found in brain tissue freshly obtained from the rat and the suggestion that it did not exist (S. and S.) was based on insufficient evidence. The effect of ether (III) in enhancing formation of II in minced brain tissue at 37° in the absence of an aq. medium was confirmed. III was highly inhibitory to formation of II in brain tissue in phosphate- or bicarbonate-Locke medium. In brain suspensions in aq. solns. both III and $CHCl_3$ rapidly broke down "bound" into free II. The effects of III on brain tissue, in the absence of an aq. medium, closely resembled the accelerating action of K ions on the formation of II in brain slices. The explanation which was suggested for the effect of K ions was also postulated for the effect of III. E. W. Scott

Do the potassium ions inside the muscle cells and blood corpuscles exchange with those present in the plasma? L. A. Hahn, G. Ch. Hevesy and O. H. Rebbe. *Biochem. J.* **33**, 1549–58(1939).—Labelled K as $K^{42}Cl$ was administered to rabbits and frogs and its penetration into the corpuscles, muscles and other organs investigated. After 1 day, corpuscles contained about 60% as much K^{42} as the same wt. of plasma. The amt. was about 30 times less than that predicted on a basis of equipartition of K^{42} between the K ions of the corpuscles and those of the plasma. The bulk of the K ions present in the corpuscles of a fully grown rabbit were therefore not replaced in the lifetime of the corpuscles. The gastrocnemius of frogs contained after 1 hr. 1.25 times and after 24 hrs. 1.35 times as much K^{42} as does the same amt. of plasma at the same time. Its labelled K content was thus about 10 times larger than would be expected on the assumption that all the K^{42} taken up by the muscles is present in the extracellular space. The amt. of K^{42} found was 20 times less than expected if an exchangeability of all the K present in the muscle cells is assumed. A similar result was obtained with rabbits. The K^{42} content of the skeleton was about double that expected if all the K^{42} is confined to the extracellular space. When labelled Na was injected about 50% of the Na of the corpuscles was replaced with Na^{24} within 1 day. Gastrocnemius tissue contained 8.5% of the Na^{24} content of the same wt. of plasma. The same figure for other tissues was much higher. The extracellular space of the total rabbit was calcd. to be 28% of the body wt. E. W. Scott

Blood-serum changes in the dog during recovery from exercise on the treadmill. Minerva Morse and F. W. Schlutz. *Am. J. Physiol.* **128**, 417–24(1940).—Serum lactate often continues to rise and bicarbonate to fall for some min. after exercise, but the fall in bicarbonate after exercise exceeds the rise in lactate. Inorg. phosphate and K fall markedly for some time after exercise but usually return to the initial level within 2 hrs. Serum chloride often continues to rise for at least 10 min. after exercise and remains above the initial level 2 hrs., but the concn. of serum protein, with few exceptions, falls rapidly below the initial level after exercise and fails to return. E. D. Walter

The effects of formalin on the hormones of human pregnancy urine. Leo Loeb and S. J. Hayward. *Am. J. Physiol.* **128**, 425–32(1940); cf. *C. A.* **33**, 9415[3].—Formalin inhibits the luteinizing effects of human pregnancy urine and if used in stronger concn. it destroys the follicular maturation effects. The action of formalin on both these hormones differs merely in a quant. manner. Different pregnancy urines differ in the concn. of formalin

needed to accomplish these effects. This is probably due to differences in the concns. of these hormones in pregnancy urine. It is possible to preserve for a long time pregnancy urine modified by formalin in such a way that it produces mainly maturation and estrogenic effects in the ovary of the guinea pig. Formalin acts in an identical manner on the hormones of cattle pituitary glands and of pregnancy urine. E. D. Walter

Effect of age and diet on electrolyte changes in rat muscle during stimulation. Leon A. Heppel. *Am. J. Physiol.* **128**, 440–8(1940).—The loss of K on stimulation of rat muscles is progressively greater as the duration of contraction is increased. After 30 min. there is no further change. The changes in chloride and water are almost maximal after 5 min. of stimulation. After 1 hr. the changes are very much reduced in magnitude. Young rats of about 6 weeks of age are able to lose more K from their muscles on stimulation than adult rats. Feeding diets low in K and poisoning with monoiodoacetic acid have little or no effect on the K changes during stimulation. E. D. Walter

The metabolism of rabbit bone marrow in serum. Charles O. Warren, Jr. *Am. J. Physiol.* **128**, 455–62 (1940).—A comparison between the metabolism of slices of rabbit bone marrow suspended in serum and in Ringer solns. E. D. Walter

The relation of renin to the adrenal gland. Ben Friedman, Eugene Somkin and Enid T. Oppenheimer. *Am. J. Physiol.* **128**, 481–7(1940).—The concn. of renin in the kidneys of cats was not reduced by adrenalectomy. After adrenalectomy in dogs there was a gradual diminution in response to renin. This was restored in part by substitution of adrenal cortical hormone. The results lend support to the hypothesis that renin is intimately concerned in the mechanism of the hypertension due to renal injuries. E. D. Walter

Evidence of pituitary involvement in the experimental control of water diuresis. Hans O. Haterius. *Am. J. Physiol.* **128**, 506–13(1940). E. D. Walter

The effect of heat on the gonadotropic pituitary antagonist. H. Jensen, Sibylle Tolksdorf and J. F. Grattan. *Am. J. Physiol.* **128**, 532–6(1940); cf. *C. A.* **33**, 6931⁹.—Various gonadotropic prepns. from sheep pituitary were subjected to heat-treatment and their gonadotropic responses studied in normal and hypophysectomized immature female rats. The follicle-stimulating hormone apparently is less stable against heating than the interstitial-cell-stimulating hormone fraction. The multiple physiol. properties of the latter fraction are destroyed by heating at approx. the same rate. E. D. Walter

The utilization of parenterally administered horse serum by the rat. T. Addis, D. D. Lee, W. Lew and L. J. Poo. *Am. J. Physiol.* **128**, 544–6(1940).—Horse serum proteins injected into the peritoneal cavity of the rat are utilized in the maintenance of the proteins of the organs and tissues of the body. E. D. Walter

Radioactive iodine as an indicator in thyroid physiology. S. Hertz, A. Roberts, J. H. Means and R. D. Evans. *Am. J. Physiol.* **128**, 568–76(1940).—By use of radioactive I as an indicator, the quantity of I taken up by the thyroid of the rabbit under various circumstances was studied. After intravenous injections, the percentage collection from any given dose reached a max. within 10 min. The normal thyroid collected up to 80 times the quantity to be expected from uniform diffusion into the general body tissues. The hyperplastic thyroid collected up to several hundred times the quantity expected from uniform diffusion. The strength of samples of radioactive I was detd., with which it will be possible to administer internal irradiation of the thyroid for therapeutic purposes. E. D. W.

The relationship between the adrenal and parathyroid glands. Charles M. Blumenfeld and Fred W. Clausen. *Am. J. Physiol.* **128**, 577–82(1940).—Changes in serum-Ca level and parathyroid vol. after adrenalectomy were studied in male albino rats 10 weeks old. The data show that adrenalectomy did not lead to hyperactivity of the parathyroids; that either there is no functional relationship or that adrenalectomy led to hypoactivity of the parathyroids, possibly because of the effect on Na metabolism. E. D. Walter

The amount of ascorbic acid excreted at each urination during twenty-four-hour periods. Jessie E. Richardson and Helen L. Mayfield. *Am. J. Physiol.* **128**, 583–7 (1940).—Two women, engaged in similar occupations, served as expt. subjects. The vol. of urine and the amt. of ascorbic acid excreted at each urination varied widely throughout the 24-hr. period. There is no correlation between the vol. of each urination and its ascorbic acid content. A wide variation is noted in the values obtained for the 6-hr. period from 7 a. m. to 1 p. m. The use of this period for detg. "resting level" is questioned. E. D. Walter

Secretion of urine in the chicken (Gallus domesticus). Harold R. Hester, Hiram E. Essex and Frank C. Mann. *Am. J. Physiol.* **128**, 592–602(1940). E. D. Walter

Absorption of chloride against concentration gradients from small intestines of rats and of rabbits. Nathan Lifson. *Am. J. Physiol.* **128**, 603–7(1940).—Chloride is absorbed against a concn. gradient from a soln. contg. approx. one-half isotonic NaCl and one-half isotonic Na_2SO_4 placed in the small intestines of albino rats and of rabbits. Blood-gut chloride concn. ratios reached are much lower than those reported for dogs under comparable conditions. E. D. Walter

Metabolism of some methylated dicarboxylic acids of low molecular weight. Rolf Emmrich. *Z. physiol. Chem.* **261**, 61–70(1939). Dogs were fed Me-substituted dicarboxylic acids and the urines analyzed. After the acid indicated the first figure gives the dose in g. per day, the second the total dose in g. and the third the percentage excreted unchanged: β-methyladipic acid, 0.49, 16, 62; *dl*-α-methylsuccinic acid (I), 0.62, 20, 44; mesaconic acid (II), 0.41, 20, 64; citraconic acid, 0.62, 20, 44; itaconic acid, 0.63, 20, 24. I also gave 1.2% of II in the urine. Milton Levy

Verzár, F.: Die Funktion der Nebennierenrinde. Basel: Benno Schwabe and Co. 266 pp. Swiss Fr. 25. Reviewed in *Nutrition Abstracts and Reviews* **9**, 788 (1940); *J. Am. Med. Assoc.* **114**, 607(1940).

G—PATHOLOGY

Acid-fast granules of different tumor tissues. II. Malignant tissues. Y. Hamazaki. *Gann* **32**, 214–17 (1938).—The acid-fast granules are rare in young rapidly growing tumors, but common in older cells. The purine content of tumors is higher than that of the parent tissues. B. C. P. A.

Serological relations between the lecithinase A of pancreas and that of animal poisons. V. Bronchi. *Sperimentale* **92**, 349–60(1938).—The lecithinase of mammalian pancreas, as well as that of bee venom, injected into rabbits or horses, acts as an antigen, in the same way as the lecithinase of snake venom. A serum immunized against any of the 3 lecithinases inactivates the other 2 *in vitro* to a considerable extent; this indicates a close chem. relation between the 3. B. C. P. A.

The sensitivity of the skin to bee venom in allergic diseases. Clinical testing of the dynamics of the course of allergic reactions. Erich Traub. *Acta Paediat.* **27**, 177–208(1939)(in German).—Bee venom is not an ordinary irritant. Because of its content of histamine and other decompn. products, as tryptophan and peptoses, bee venom is intimately connected with the chemistry of antigen-antibody reaction. Ruth Berggren

Second series of researches on the chemism of the marrow fluid obtained by sternal puncture: the marrow sugar in anemia. R. Benda and J. Nicolas. *Bull. mém. soc. méd. hôp. Paris* **55**, 1229–36(1939); cf. *C. A.* **33**, 5479¹,².—In all the anemia patients studied the marrow sugar tended, in general, to be higher than the blood sugar. The differences between the 2 values were usually

most evident in the 2nd, 3rd or 4th fractions of the marrow fluid, i. e., in the 6th, 10th or 12th cc. taken for analysis. The sugar content of different fractions of the marrow fluid obtained by successive aspirations also showed more or less marked differences. In anemia this tendency to a high marrow glucose was often accompanied by a lowering of the blood sugar toward the lower physiol. limits or even below these limits. The above findings were most distinct in the 5 cases of Biermer's anemia. The marrow glucose was normal in 3 patients in whom the cell count did not fall below 3,000,000. This was not true in Biermer's anemia, where the cell count often fluctuated during treatment. But with this reservation it appeared that with less than 3,000,000 red cells and regardless of the type of anemia the magnitude of the high marrow glucose was independent of the degree of anemia. The role of the variations in the red cell count was difficult to est. since (1) a lowering appeared in itself capable of affecting the marrow glucose and (2) the increase in the cell count did not prevent the appearance of modifications in the sugar content. The tendency to a high marrow glucose in anemia or chlorosis was apparently not related to the predominance of any of the elements ordinarily composing the medullogram (erythroblasts, myelocytes, eosinophiles, etc.). Moreover, it was evidently not affected by treatment. These observations do not permit a physicochem. classification of the anemias based on the ideas of "active" high marrow glucose and low marrow Fe. R. Berggren

Purpura hemorrhagica due to ingestion of sedormid (allylisopropylacetylcarbamide). Ernest H. Falconer and Irwin C. Schumacher. *Arch. Internal Med.* **65**, 122–37(1940).—Neither oral (nor parenteral) administration of vitamin C diminished the intensity of the purpuric lesions and hemorrhagic manifestations in purpura hemorrhagica. J. B. Brown

Allergy. Francis M. Rackemann. *Arch. Internal Med.* **65**, 185–212(1940).—A review of the literature of 1939. J. B. Brown

The magnesium content of the erythrocytes in pernicious and some other anemias. Ole Bang and Søren L. Ørskov. *J. Clin. Investigation* **18**, 497–500(1939).—In anemia from various causes there is often, but not always, an increased Mg content of the red cells, an indication of a preponderance of young cells. In pernicious anemia high Mg values are found during relapse, and they decrease during remission. These findings support the view that a short lifetime of the red cells, with a concomitantly increased rate of destruction, is a decisive factor in the development of the anemia. J. B. Brown

Clinical studies on the blood volume. VII. Changes in blood volume in Bright's disease with or without edema, renal insufficiency, or congestive heart failure, and in hypertension. Alfred W. Harris and John G. Gibson, 2nd. *J. Clin. Investigation* **18**, 527–36(1939); cf. *C. A.* **32**, 7941[1].—In Bright's disease blood vol. tends to vary directly with the serum albumin concn. and blood nonprotein N concn. and indirectly with the degree of anemia. Hypoproteinemia diminishes in the edematous stage. Anemia, if present, augments the plasma vol. The plasma vol. tends to increase during diuresis, especially the albumin fraction of the serum protein. J. B. B.

Inability to demonstrate a platelet-reducing substance in an acetone extract of the spleen from patients with idiopathic thrombocytopenic purpura. Frederick J. Pohle and Ovid O. Meyer. *J. Clin. Investigation* **18**, 537–41 (1939).—An acetone ext. of the spleen of patients with chronic idiopathic thrombocytopenic purpura does not contain a substance capable of reducing the no. of blood platelets in rabbits. J. B. Brown

The blood-V factor (coenzyme) level in normal and pathological subjects. Henry I. Kohn, Frederick Bernheim and Anton V. Felsovanyi. *J. Clin. Investigation* **18**, 585–91(1939).—The V-factor (coenzymes one and two, plus possible unknown related substances) was detd. in a large group of normal subjects and hospital patients. Activity was expressed in d. e. (gamma of coenzyme one per cc. of corpuscles). Eighty-one % of the normal and 65% of the pathol. cases fell in the range 50–80 d. e. Diabetic patients showed low values and patients with pulmonary disease high. J. B. Brown

Ultrafiltrable magnesium in hyperthyroidism. Louis J. Soffer, D. Alfred Dantes, Edward B. Grossman, Harry Sobotka and Mildred D. Jacobs. *J. Clin. Investigation* **18**, 597–601(1939).—Total serum and ultrafiltrate Mg were detd. in a group of normal and pathol. patients. Normal bound Mg varied from 3.1 to 22.1%. Normal values were found in neurocirculatory asthenia and various types of muscular dystrophy; high values occurred in hyperthyroidism, with a decrease after lugolization. In 2 patients with myxedema there was no bound Mg. J. B. Brown

The coagulation defect in hemophilia: the clot-promoting activity in hemophilia of Berkefelded normal human plasma free from fibrinogen and prothrombin. Eugene L. Lozner, Robert Kark and F. H. L. Taylor. *J. Clin. Investigation* **18**, 603–8(1939).—Methods for the removal of prothrombin and both prothrombin and fibrinogen from plasma are described. When either one or both are so removed, the residual plasma is still capable of reducing the coagulation time of hemophilic blood *in vitro*, and in patients with hemophilia. J. B. Brown

The occurrence of abnormal dark adaptation and its relation to vitamin A metabolism in patients with cirrhosis of the liver. Arthur J. Patek, Jr., and Charles Haig. *J. Clin. Investigation* **18**, 609–16(1939).—Abnormal dark adaptation, observed in 19 of 24 patients with cirrhosis of the liver, persists on a diet rich in vitamin A and is explained as an alteration in the metabolism of vitamin A in such patients. J. B. Brown

Influence of an acetaldehyde derivative and diformaldehyde peroxide on anaphylactic shock in guinea pigs. J. Maisin and Yu Han Tang. *Compt. rend. soc. biol.* **132**, 313–15(1939); cf. *C. A.* **32**, 6321[4]; **33**, 650[9].—AcH was dehydrated with concd. H_2SO_4 and a product obtained which in extremely small doses (1–3 injections of 2 cc. of a $1/10^{18}$ soln.) desensitized for several months guinea pigs sensitized to egg white. Similar doses of cryst. diformaldehyde peroxide, m. 64–5°, desensitized for a few days after which the animals became hypersensitive. L. E. Gilson

Prophylaxis of cancer caused by *o*-aminoazotoluene and dimethylaminoazobenzene. Presence of antiblastic substance in whole rye meal. J. Maisin, Y. Pourbaix and E. Cuvelier. *Compt. rend. soc. biol.* **132**, 315–18(1939).—Rats were fed 10 mg. per day of one of the above compds. with their diet. If the diet consisted principally of polished rice they all developed hepatomas and died, but if fed ground whole rye they remained healthy. The presence of an antiblastic substance in rye is suggested. L. E. Gilson

Bilirubin, urobilin and the "yellow diazo reaction" of the serum in pneumonia and bronchopneumonia. B. Varela Fuentes, R. Canzani and A. Graña. *Compt. rend. soc. biol.* **132**, 507–9(1939).—See *C. A.* **33**, 8767[2]. L. E. Gilson

The pH of systemic blood in normal and hypertensive dogs, determined by means of a syringe-type electrode. Otto H. Müller and Wm. F. Nickel. *Proc. Soc. Exptl. Biol. Med.* **43**, 89–92(1940).—No relation was found between variations in blood pressure and pH. Apparently the buffering capacity of the systemic blood is sufficient to offset the introduction of an alk. or acid substance if such is produced during exptl. ischemia of the kidney. L. E. Gilson

Induction of lymphomatosis in mice following painting with 9,10-dimethyl-1,2-benzanthracene. L. W. Law and Marjorie Lewisohn. *Proc. Soc. Exptl. Biol. Med.* **43**, 143–6(1940).—A 0.3% soln. of 9,10-dimethyl-1,2-benzanthracene (cf. *C. A.* **32**, 4978[3]) was applied twice a week to the skin of mice of the dilute brown strain. After 65–90 days many of the mice showed a general lymphomatosis with bilateral lymphadenopathy of the axillary, inguinal and cervical lymph nodes. L. E. Gilson

Free and combined silica in silicotic lungs. Guy E. Youngburg and Mamie V. Youngburg. *Proc. Soc. Exptl. Biol. Med.* **43**, 146–8(1940).—Analyses of 14

silicotic human lungs are given. Total silica ranged from 0.086 to 1.296% of the dry tissue. Free silica ranged from 3.25 to 91% of the total. L. E. Gilson

Prothrombin levels and synthetic vitamin K in obstructive jaundice of rats. Joseph E. Flynn and E. D. Warner. *Proc. Soc. Exptl. Biol. Med.* **43**, 190–4(1940).—Rats were kept on a diet low in vitamin K. Three days after ligation of the bile duct the blood prothrombin decreased to 10–25% of the normal. At this point a single intraperitoneal dose of 20 γ of 2-methyl-1,4-naphthoquinone raised the prothrombin level to 81% of the normal in 24 hrs. The 2-methyl-1,4-naphthoquinone was approx. 500 times as active as phthiocol. Rats are able to store considerable vitamin K. L. E. Gilson

Composition of bone in extreme osteoporosis associated with hepatoma. Arild E. Hansen, L. S. Palmer and J. Wesley Nelson. *Proc. Soc. Exptl. Biol. Med.* **43**, 206–7 (1940).—The dry, lipide-free rib bones of a hepatoma patient had 31.4% less Ca, 33.8% less P, 39.0% less Mg and 37.9% less CO_2 than those of the control. L. E. Gilson

An agglutinable factor in human blood recognized by immune serums for Rhesus blood. Karl Landsteiner and Alexander S. Wiener. *Proc. Soc. Exptl. Biol. Med.* **43**, 223(1940). L. E. Gilson

Proteolysis of diphtheria antiserum by pepsin. Fernando Modern and Guillermo Ruff. *Rev. inst. bacteriol. dept. nacl. hig.* (Buenos Aires) **9**, 197–215(1939); cf. *C. A.* **33**, 2583[1], 8769[3].—Diphtheria antiserum was digested with pepsin under a variety of conditions. In all cases 30–60% of the antitoxic activity was destroyed. L. E. Gilson

Clinico-experimental studies on the fate of exogenous sugar which is not polymerized to glycogen during spontaneous or provoked creatinuria. Leonardo Mazzoleni. *Arch. studio fisiopatol. clin. ricambio* **7**, 237–59(1939).—During creatinuria, exogenous sugar was not eliminated, synthesized to glycogen, oxidized or esterified with P_2O_5. Its fate was considered open to hypothesis. H. L. G.

Insulo-pancreatic influence on the synthesis of hippuric acid. Studies on normal and diabetic persons and those with liver diseases. Fabio Tronchetti. *Arch. studio fisiopatol. clin. ricambio* **7**, 261–85(1939).—In diabetic individuals there was a deficient synthesis and elimination 6 of hippuric acid. Insulin increased the synthesis and elimination in all 3 groups and indicated the importance of the pancreas in the regulation of hepatic processes. Helen Lee Gruehl

Urobilinemia and hemoglobin metabolism. Hemoglobin metabolism in nephritis and diabetes. G. Sotgiù and F. Volpe. *Atti soc. med. chir. Padova* **17**, 219–23 (1939).—In nephritis and diabetes there occurred a retention of blood urobilin, low fecal bilin and relative increase of urinary bilin. Helen Lee Gruehl

Anaphylactogenic properties of the products of papain digestion of seroproteins and egg albumin. Mario Calcinai. *Boll. ist. sieroterap. milan.* **18**, 594–613(1939).—The dialyzate of the digestive products could sensitize but not produce shock. The residual products after dialysis maintained both sensitizing and shocking properties. Papain itself was anaphylactogenic. H. L. G.

Commercial papain as an anaphylactogen. Mario Calcinai. *Boll. ist. sieroterap. milan.* **18**, 677–82(1939). Helen Lee Gruehl

Pathogenesis and therapy of progressive muscular dystrophy. Giulio Camerini. *Minerva med.* **1939, II**, 293–7.—After prolonged treatment with active pancreatic exts. in 5 persons with muscular dystrophy there were practically no modifications in the elimination of N and creatine bodies and no improvement in the clinical symptoms. Helen Lee Gruehl

Blood cholesterol in chronic articular diseases. Giuseppe Michetti. *Minerva med.* **1939, II**, 501–5.—In a study of 84 cases the majority showed a cholesterol titer within high normal limits. In cases of definite infective character there was a slight diminution of blood cholesterol. The cholesterol values were of no diagnostic importance in these diseases. Helen Lee Gruehl

chlorides in H. D. Barnes. *S. African J. Me* 7–110(1939).—The chloride content of the uid is lower in severe than in mild meningitis. The likelihood of death does not appear to be greater in the cases with lower chloride content of the fluid obtained at 1st puncture. The chloride curve in pneumococcal meningitis shows no tendency to rise. When chloride values are within normal limits or, if initially low, the curve rises during subsequent days, the 2 disease is likely to run a mild course and conversely. The likelihood of death is not significantly greater if the curve falls during the first few days. Two references are given. W. R. Henn

Study of the renal factor in cardiac patients by measurement of Van Slyke's coefficient. Jean F. Porge. *Arch. maladies coeur vaisseaux* **32**, 469–77(1939).—Van Slyke's coeff. of urea clearance was normal (92–104%) 3 in 4 patients with compensated cardiac valve lesions, low (41–62%) in 9 out of 10 patients with decompensated valvular lesions, and rather low in most of 10 patients with hypertension. Data are also given on the blood N and on Ambard's const. in the same patients. Marion Horn

Origin of induced pulmonary tumors in strain A mice. Hugh G. Grady and Harold L. Stewart. *U. S. Pub. Health Repts.* **55**, 169–70(1940).—Pulmonary tumors 4 induced in strain A mice arise from alveolar cells and begin to appear 5 weeks after subcutaneous injection of carcinogenic hydrocarbons. The development of these tumors in the lung is not assocd. with any demonstrable inflammatory action. J. A. Kennedy

Chemistry of lipoidosis. III. Niemann-Pick's disease and amaurotic idiocy. E. Klenk. *Z. physiol. Chem.* **262**, 128–43(1939); cf. *C. A.* **29**, 6942[3].—The lipoids from the brain in various lipoidoses were fractionated. Compared to the lipoids from Niemann-Pick's disease (3 cases) the lipoids from infantile amaurotic idiocy (Tay-Sachs) contain considerably less sphingomyelin and much more of a new glycolipide (substance X). The latter is extd. chiefly by hot $CHCl_3$-MeOH (1–3) from the organ powder after acetone- and ether-sol. constituents have been removed. X contains much more sugar than normal cerebrosides. It contains fat acids, a N base very like or identical with sphingosine, besides the reducing sugar. There is no cerebronic acid present in it. In 5 cases of juvenile amaurotic idiocy the changes were not so marked, probably because of localization of the lesions to certain centers. Milton Levy

Electrophoretic separation of the antibody from human allergic serum. John M. Newell, Alexander Sterling, Morris F. Oxman, Samuel S. Burden and Laura E. Krejci. *J. Allergy* **10**, 513–20(1939).—The Tiselius app. 7 (*C. A.* **31**, 4353[9]) was used to fractionate serums. The serums were dialyzed 2 days in the refrigerator against a physiol. saline soln. contg. as a buffer 0.02 *M* of phosphates at pH 8.10 and were then subjected to electrophoresis with a current of 20 ma. No electrophoretic sepn. bands in human serums were found denoting fractions other than albumin and 3 globulins, α, β and γ. The anomalous band called δ globulin was frequently found in concd. 8 serums, but this was considered merely an effect of concn. No distinction could be found between allergic and normal serums. When the solns. in the different sections of the app. were tested, the skin-sensitizing antibody of allergic serum and the antitoxin against staphylococcus hemolysin in human serum were found only in those contg. γ globulin. The antibody for ragweed in rabbit serum was found in the same fraction. Julian H. Lewis

The total water and sodium exchanges in asthmatic 9 **patients.** John Sheldon, Homer Howes and Geo. Stuart. *J. Allergy* **11**, 1–13(1939).—During an attack of asthma there was a definite loss of body H_2O for at least 24 hrs. and a corresponding increase of urinary Na. Since the heat production during asthma was not elevated the observed loss in body wt. was due to loss of body water. Julian H. Lewis

The thermolability of ragweed pollen extract and its corresponding reagin. Carl E. Arbesman and Harry

Eahle. *J. Allergy* **11**, 18–27(1939).—Ragweed pollen exts. have been found to be highly thermolabile. Approx. 75% of their reagin-neutralizing activity is destroyed within 15 min. at 56°, 90% within 1 hr. and over 95% in 4 hrs. The reagin-neutralizing activities of 4 similar ragweed pollen exts. prepd. in 1939, 1937, 1933 and 1929 and since stored at 4°–8° were found to be 100, 16, 4.5 and 1.2., resp., indicative of a fairly rapid deterioration. Despite the widely differing biol. activities of these 4 exts., their N contents and the ratio of protein N/total N were of the same order of magnitude, a fact which does not exclude the possibility that the reactive constituent is a protein. Short ragweed pollen reagin has also been found to be highly thermolabile. On heating at 56° approx. 50% of the skin-sensitizing activity was destroyed within ½ hr., approx. 90% within 2 hrs. and approx. 99% within 4 hrs. Julian H. Lewis 1

A micro blood esterase determination applied to studies of rats bearing adenocarcinoma. E. Elizabeth Troescher and Earl R. Norris. *J. Biol. Chem.* **132**, 553–7(1940).—In rats with implanted adenocarcinomas the esterase activity of the blood during the growth of the tumor fell far below the range of fluctuation of values for normal rats. In animals exhibiting receding tumors, the esterase activity rose toward normal values with recession of the tumor. A micromethod is described for *the detn. of blood esterase* in 0.05 cc. of blood which gives results usually checking to within 0.02 pH for the amt. of acid liberated from Et butyrate. A. P. Lothrop 2

The metabolism of pyruvic acid. Hans von Euler and Bertil Högberg. *Arkiv Kemi, Mineral. Geol.* **13B**, No. 16, 5 pp.(1939)(in German); cf. *C. A.* **33**, 9424[9].—After implantation of Jensen sarcoma the blood $AcCO_3H$ (I) (detd. by method of Lu, *C. A.* **33**, 6896[2]) was increased 2–4 times over that of normal rats (12 γ/cc.). The higher values were associated with the older tumors. No increase followed implantation of muscle tissue. A comparable rise accompanied the fever caused by infection with colon organisms, but the tumorous rats did not have fever. Injection of 100–200 γ of aneurin lowered the blood I markedly. Similar high values were found in a rabbit implanted with Brown-Pearce sarcoma. Two human cancer patients showed only a slight increase in the blood I. H. L. Mason 3

The significance of circulation in the pathogenesis of extrarenal azotemias. P. Gömöri, L. Podhradszky and J. Kring. *Acta Med. Scand.* **102**, 591–610(1939).—Cases of N retention are described resulting from loss of salt. A diminished filtration pressure and decreased blood flow are considered the actual factors occasioning the retention. The N retention occurring after hemorrhage is explained on the same basis of circulatory changes. The favorable effect of hypertonic salt soln. is attributed not only to the restoration of the salt concn. but also to the improvement of the circulation. S. Morgulis 4

Hematopoiesis and endogenous uric acid. Roald Opsahl. *Acta Med. Scand.* **102**, 611–28(1939).—An increased elimination of uric acid, chiefly of endogenous origin, was observed during the reticulocyte crisis in 5 cases of pernicious anemia and 2 cases of hemorrhagic anemia. It is suggested that there is a connection between endogenous uric acid and blood regeneration. During active blood regeneration increased amts. of purines are liberated and cause an attack of gout in persons of such a constitutional disposition. Two severe anemia patients are described in whom this condition was observed when the blood regeneration was at its max. S. Morgulis 5

The comparative iodine content of blood and cerebrospinal fluid. Karl P. Klassen, Ruth L. Bierbaum and Geo. M. Curtis. *J. Lab. Clin. Med.* **25**, 383–7(1940).—Iodine detns. by the method of Matthews, Curtis and Brode (*C. A.* **32**, 9138[9]) were made on whole blood and cerebrospinal fluid of 2 groups of patients. In group 1 (10 patients without thyroid disease, fever or meningeal disease, and on a relatively low I intake for at least one month) the av. blood I was 3.6 γ %, the range 2.9 to 5.1; in group 2 (10 patients with hyperthyroidism, who had not received I for one month) the av. blood I was 8.8 γ %, the range 5.1 to 15.7. The increase in blood I was most marked in those patients with a more recent onset of the disease. The av. cerebrospinal fluid I in both groups was 0.5 γ %. Conclusion: Iodine is a normal constituent of the cerebrospinal fluid and its concn. is not increased in patients with hyperthyroidism without meningeal involvement, fever and I therapy. Howard W. Robinson 6

The effect of alkalosis on the blood picture in chronic splenomyelogenous leucemia. Robert D. Barnard and Perry W. Ross. *J. Lab. Clin. Med.* **25**, 345–8(1940).—The induction of a period of alkalosis by the administration of large doses of $NaHCO_3$ to 2 adult male patients did not stimulate myeloblastic activity and during this period there seemed to be a tendency toward inhibition of leucopoiesis. The alkalosis was judged from the clinical symptoms. Conclusion: The study furnishes evidence against the relationship of alkalosis to neoplasia. Howard W. Robinson 7

The sources of the enzymes of normal and pathologic cerebrospinal fluid. Irving Kaplan, David J. Cohn, Abraham Levinson and Beatrice Stern. *J. Lab. Clin. Med.* **25**, 495–505(1940); cf. *C. A.* **33**, 8782[7].—A discussion is given of the 2 possible sources of the enzymes in normal fluid (blood plasma and neural tissue fluid). Tryptic and phosphatase activities of the fluid of purulent meningitis are due mostly to the desmotrypsin and the desmophosphatase, resp., of the polymorphonuclear cells; the lipase, tributyrinase and esterase activities are due in part (about 50%) to the desmolipolytic enzymes and the amylase activity is due, in a lesser degree, to the desmoamylases of these cells; the remainder of the enzymic activity in this disease is probably due to lyoenzymes of the same cells and to plasma enzymes which enter the fluid because of increased permeability. The antitryptic power of the fluid of tuberculous meningitis varies with pH in the same manner as serum antitrypsin; this suggests that the antitrypsin enters from the blood plasma because of increased meningeal permeability. The enzymic activity of the fluid in tuberculous meningitis which is not due to the polymorphonuclear cells or to the passage of plasma enzymes across the meningeal barriers is due to the presence of lymphocytes which are particularly rich in lipolytic enzymes. The sources of the enzymes in the fluids in hydrocephalus and brain tumor are discussed. Howard W. Robinson 8

The histidine content ("diazo value") of the blood in peptic ulcer. E. G. Schmidt. *J. Lab. Clin. Med.* **25**, 512–14(1940).—The blood from patients and controls shows no differences in the values given by various diazotization procedures (methods of Schmidt, *et al.*, *C. A.* **31**, 8646[4], and Theis and Benedict, *C. A.* **18**, 3398). The data do not confirm the theory that a histidine deficiency exists in the blood of patients with peptic ulcer. Howard W. Robinson 9

The Lange test. II. The influence of particle size and hydrogen-ion concentration of gold sols upon Lange test readings on syphilitic and tabetic spinal fluids. P. K. Glasoe and C. H. Sorum. *J. Lab. Clin. Med.* **25**, 534–7 (1940); cf. *C. A.* **34**, 512[3].—The sensitivity of the test in syphilitic and tabetic spinal fluids, as in that of paresis, increases with increase in particle size of the Au sol and decreases with increase in pH. Howard W. Robinson 10

Histological changes and transplantation of tissue surrounding methylcholanthrene pellets during the latent period of tumor development in female C_3H mice. Harold L. Stewart. *Am. J. Path.* **15**, 707–22(1939).—C_3H mice injected subcutaneously with 5% methylcholanthrene-cholesterol pellets yielded tumor-producing transplants when sacrificed at 42 and 49 days and at 77, 82, 91 and 98 days. Plain cholesterol pellets caused only a chronic foreign-body reaction. Numerous atypical cells were observed also in histological sections from mice sacrificed earlier than the 42nd day and also later, even when the transplant failed to yield tumors, a suggestion that other unknown factors are necessary for the development of tumors upon transplantation. F. B. Seibert 11

The effect of Korean ginseng on serum anaphylaxis. Heiki Lee. *J. Chosen Med. Assoc.* **29**, 2431–6(English abstr. 149–51)(1939).—The daily administration of 0.5 g. of Kaijo (Song-do) ginseng to the guinea pigs during the initial and reinjection periods reduces the symptoms of serum anaphylactic shock and prolongs the survival time. It also reinforces the effect of vagotomy on the shock. S. Tashiro

Electrophoresis of animal viruses and their neutralizing antibodies in low concentrations. Alfred Polson. *Nature* **145**, 27(1940).—An app. is illustrated and described for study of the mobility of animal viruses and their neutralizing antibodies in an elec. field. It is a simplified modification of the Tiselius moving boundary method. Cf. *C. A.* **31**, 8310[4]. E. D. Walter

The time factor in solubility of [antigen-antibody] precipitates in excess of antigen. Wm. C. Boyd. *J. Immunol.* **38**, 143–6(1940).—Ppts. were obtained by mixing ovalbumin and rabbit antiovalbumin serum in optimal proportions. The soly. of these ppts. in varying amts. of ovalbumin was tested immediately and after an interval of 10 months. In both cases the ease and completeness of solution was similar: 2.144 mg. of antigen-N (32 times the amt. used in making the ppt.) was sufficient to dissolve almost completely a ppt. contg. 0.633 mg. of N. Smaller amts. of antigen gave correspondingly less soln. It is suggested that the soln. of such ppts. represents a reversal of all or some of the reactions involved in their formation. The combination between ovalbumin and antiovalbumin, at least, has not become any less reversible with time. Charles A. Zittle

The construction of graphs and tables for evaluation of the quantitative complement-fixation reactions and reaction ratios. Wm. R. Thompson and Frank Maltaner. *J. Immunol.* **38**, 147–57(1940).- Mathematical. Charles A. Zittle

Quantitative relations in complement-deviation reactions. Adolph L. Kappus and Annelise Winkler. *Z. Immunitäts.* **95**, 1–8(1939).—The range of error in the hemolytic system increases with the amt. of amboceptor used. It is least with an active complement and the smallest quantity of amboceptor that is necessary. It is independent of the titer of amboceptor in an antiserum. The relation between the amt. of hemolysin and the concn. of red cells is a linear function. The quantity of red cells and the quantity of amboceptor used up are also proportional. Julian H. Lewis

H—PHARMACOLOGY

CARL F. SCHMIDT

Pathways of absorption of sodium ferrocyanide from the subarachnoid space into the venous system. R. O. Scholz and E. M. Ralston. *Anat. Record* **75**, 365–71 (1939). Philip D. Adams

Permeability and absorptivity of the skin. Joseph J. Eller and Shirley Wolff. *Arch. Dermatol. Syphilol.* **40**, 900–23(1939).—Fats permeate the skin and do so in a large measure along the hair shafts and into the oil-gland ducts. Liquid fats permeate more rapidly than solid fats. Animal fats show the greatest depth of penetration, with vegetable fats next and mineral fats least. Most of the fats show optimum penetration in 4 to 6 hrs. after application. After 6 hrs. the quantity of fat in the deeper tissues appears to diminish. Philip D. Adams

Treatment of fungous infections with ethyl iodide inhalations. Jacob H. Swartz. *Arch. Dermatol. Syphilol.* **40**, 962–73(1939).—An improved inhalation device is described. The excretion of EtI from the body is discussed. Philip D. Adams

Action of sympathomimetic drugs on the fall of blood pressure produced by quinine. H. Konzett. *Wien. klin. Wochschr.* **52**, 48–9(1939).—The fall of arterial blood pressure, produced by intravenous or intra-aortal injection of 3 mg. of quinine into cats under urethan-chloralose anesthesia, can be prevented by simultaneous injection of 60 γ of adrenaline, 0.6 mg. of *m*-synephrine, or 6–9 mg. of synephrine. B. C. P. A.

Effectiveness of intravenous hypertonic sucrose and adrenaline in the treatment of status asthmaticus. E. L. Keeney. *J. Allergy* **9**, 497–502(1938); cf. *C. A.* **32**, 8559[1].—In status asthmaticus 4 out of 6 patients experienced immediate relief after intravenous injection of 100 cc. of 50% sucrose with 0.5 cc. of $^1/_{1000}$ adrenaline. B. C. P. A.

Thiocyanate dermatitis. Mervin E. Green and James S. Snow. *Arch. Internal Med.* **64**, 579–85(1939).—An allergic reaction to KCNS is described, along with blood thiocyanate findings. J. B. Brown

Effect of the reticulocytogenic principle in urine in the treatment of pernicious anemia. G. E. Wakerlin. *Arch. Internal Med.* **65**, 21–5(1940).—The reticulocytogenic principle in urine is not effective orally in the treatment of pernicious anemia. The antipernicious anemia principle of the liver is not excreted in demonstrable quantities in normal human urine. The kidney principle which is reticulocytogenic for the pigeon is without effect in pernicious anemia. J. B. Brown

The rate of attainment of diffusion equilibrium for thiocyanate between plasma and transudates following the intravenous injection of sodium thiocyanate in patients with edema. D. Rourke Gilligan and Mark D. Altschule. *J. Clin. Investigation* **18**, 501–6(1939).—Although diffusion equil. for CNS^- following injection of NaCNS in normal subjects obtains in 1 hr., in patients with accumulations of edema fluid this equil. between plasma and the transudates is not complete until 6–10 hrs. after the injection. The time required is proportional to the vol. of transudate. At equil. the CNS^- concns. were 0–20% higher in the sera. J. B. Brown

The formation of methemoglobin and sulfhemoglobin during sulfanilamide therapy. J. S. Harris and H. O. Michel. *J. Clin. Investigation* **18**, 507–19(1939).—Blood samples (960) from 476 patients receiving sulfanilamide (*S*) were examd. for *S*, methemoglobin (*MH*) and sulfhemoglobin (*SH*), either by the hand spectroscope or quantitatively by the spectrophotometer. The bloods showing *MH* were highest in the group of high content of *S*. The av. *MH* content was proportional to the *S* concn. After a single dose of *S*, the max. *MH* occurred several hrs. after max. blood *S* peak. *SH* was more frequent after long courses of *S* but bore no relationship to age, sex or concn. of *S* or *MH* in the blood. It seems that an active substance is normally produced in the course of *S* metabolism which causes the production of *MH* and *SH*. Methemoglobinemia depends upon: formation of the active agent, oxidation of hemoglobin under the influence of the active agent, and reduction of *MH* by the body. J. B. Brown

The formation in vitro of an oxidizing agent by surviving tissues and sulfanilamide. J. S. Harris. *J. Clin. Investigation* **18**, 521–6(1939).—Sulfanilamide does not function as an oxidizing agent on hemoglobin, but upon reaction of certain tissues (liver, kidney, etc.) with sulfanilamide, an oxidizing agent results which does form methemoglobin. J. B. Brown

The treatment of acute alcoholism with glucose and insulin. Walter Goldfarb, Karl M. Bowman, Sam Parker and B. Krautman. *J. Clin. Investigation* **18**, 581–4(1939).—Injection of 15 units of insulin had no effect on blood alc. in intoxicated patients; intravenous glucose slightly lowered blood alc. only in the severely intoxicated. Injection of both glucose and insulin accelerated disappearance of blood alc. in all patients, suggesting that oxidation of glucose catalyzes oxidation of alc. J. B. Brown

Coal-tar-pitch poisoning in pigs. Robert Graham, H. R. Hester and J. A. Henderson. *J. Am. Vet. Med. Assoc.* **96**, 135–40(1940).—Coal-tar-pitch poisoning may be responsible for spontaneous outbreaks of liver degeneration in pigs. Rachel Brown

Comparative glycogen formation in the livers and muscles of rats fed different sugars under normal and pathological conditions. II. Experiments on phosphorus-poisoned starving rats. Ya. Z. Spektor. *Méd. exptl.* (Ukraine) **1939**, No. 4, 38–43.—Expts. were performed on 170 rats which received 2 subcutaneous injections (with a

1-day interval between the 2 injections) of a 0.5% soln. of yellow P in sunflower-seed oil, each dose being calcd. on the basis of 0.1 cc. of the soln. for each 100 g. of body wt. The glycogen expts. were performed 1 day after the last injection. In normal and P-poisoned rats after sugar feeding the percentage increase in liver glycogen was greater than that of muscle glycogen. In both kinds of rats fructose and invert sugar were most effective in producing liver glycogen, while sucrose, galactose and invert sugar were most effective in muscle glycogen formation. In P-poisoned rats the glycogen content of the livers after a 20-hr. period of hunger or after sugar feeding (with the exception of galactose) was markedly lower than in the normal rats, while the glycogen content of muscle was similar to that of normal rats under the same conditions. All the sugars were almost completely absorbed from the intestine 4 hrs. after feeding, both in the normal and P-poisoned rats. S. A. Corson

The detoxication mechanism. I. The ability of the apple or its constituents to counteract the toxic effects of lead and arsenic. Ira A. Manville, Francis J. Reithel, Paul M. Yamada, T. W. Spencer and John R. Richardson. *J. Ind. Hyg. Toxicol.* **22**, 36–47(1940).—Rats, guinea pigs and rabbits were fed on diets low in uronic acid. With the exception of the rat diet, the food mixts. were low in Ca and P. The animals were fed Pb, sep. from the diet, in amts. of 47, 19.6 and 6.4 mg. per kg. of body wt. Apple supplements were fed to the group-A animals to the extent of 35, 49, and 18.3 g. per kg. of body wt. The ratio of Pb to apple was 0.74 for the rats, 2.5 for the guinea pigs and 3.0 for the rabbits. In no instance did the duration of the feeding extend over 33 days for the rats, 8 days for the guinea pigs or 26 days for the rabbits. The animals receiving the highest proportion of apple (rabbits) showed no signs of toxicity, and there was 100% survival. As the amt. of apple decreased, the protection afforded was still evident, but less marked. A. L. E.

Comparative physiological effects of pure, commercial and crude benzenes. H. H. Schrenk, W. P. Yant, S. J. Pearce and R. R. Sayers. *J. Ind. Hyg. Toxicol.* **22**, 53–63(1940).—Dogs and guinea pigs were exposed to the same concns. of the vapors. Physiol. effect is apparently due primarily to the C_6H_6 content of the benzenes and not to impurities. A. L. Elder

The acute vapor toxicity of allyl chloride. E. M. Adams, H. C. Spencer and D. D. Irish. *J. Ind. Hyg. Toxicol.* **22**, 79–86(1940).—It is among the most toxic of the halogenated aliphatic hydrocarbons. Rats and guinea pigs exposed to 100 mg. per liter died in a short time. A. L. Elder

Sanocrysin treatment from 1923 to 1938. Knud Secher. *Acta Tuberc. Scand.* **13**, 193–220(1939).—The toxic symptoms from sanocrysin treatment are to be regarded as a systemic tuberculin reaction called forth by the drug. The small dose precludes drug intoxication. Vitamin supplements (A, B_1, B_2 (lactoflavin) and C) given 8 days before treatment mitigate or largely eliminate the undesirable reactions. Polyarthritis cases are reported to be benefited by sanocrysin therapy. H. R. Getz

Inhibiting action of amyl nitrite and caffeine on adrenaline-chloroform and adrenaline-benzene syncopes. L. Dautrebande and R. Charlier. *Compt. rend. soc. biol.* **132**, 292–6(1939).—In dogs the inhalation of a small amt. of amyl nitrite or the intravenous injection of a large dose of caffeine simultaneously with the adrenaline prevented the syncope. The mechanism of the action is uncertain. L. E. Gilson

Comparative action of chemically pure benzene and commercial crystallizable benzene on the volume of the dog heart. J. Barzin and R. Charlier. *Compt. rend. soc. biol.* **132**, 296–9(1939); cf. *C. A.* **33**, 4673[8], 5496[1].—Inhalation of sufficient C_6H_6 vapor caused the heart to increase in size and eventually go into fibrillation. The com. C_6H_6 was the more toxic. L. E. Gilson

Sensitization to the hyperthermic action of dinitro compounds by metabolites. H. Handovsky, H. Casier and A. L. Delaunois. *Compt. rend. soc. biol.* **132**, 300–3 (1939).—In pigeons the hyperthermic action of dinitrocresol was increased by intramuscular injections of small amts. of AcH, AcOH, glycine, creatine or methylguanidine. EtOH had no effect. In guinea pigs AcOH had the same effect as in pigeons but creatine had no effect. **Production of strongly reducing substances, especially ascorbic acid, in the muscles of pigeons and guinea pigs after administration of dinitrocresol and metabolites.** *Ibid.* 303–7.—In all the above expts. whenever the hyperthermic action of dinitrocresol was increased by the substance injected the ascorbic acid and total reducing power of the muscles were increased. Ascorbic acid itself sensitizes pigeons to the action of dinitrocresol. L. E. G.

Chemosensitivity of the hypertensive reflexes of the auricles to various toxic compounds. Henri de Waele and Jean VandeVelde. *Compt. rend. soc. biol.* **132**, 310–11(1939).—In rabbits with the carotid sinus isolated from the circulation the intravenous injection of small doses of nicotine, ephedrine or coniine produced a rise in blood pressure, with slight bradycardia and increase in respiration, by stimulation of the reflex centers of the auricles. Cutting certain spinal nerve roots abolished the reflexes. **Reaction of the auricle reflexes to breathing excess oxygen and compressed air.** *Ibid.* 312.—In the above rabbits an increase in O supply caused a decrease in rate of respiration through stimulation of the auricle reflexes. L. E. Gilson

Does alcohol stimulate gastric secretion by liberating histamine? Carl A. Dragstedt, John S. Gray, Alfred H. Lawton and Max Ramirez de Arellano. *Proc. Soc. Exptl. Biol. Med.* **43**, 26–8(1940).—Yes. L. E. Gilson

Toxic and therapeutic response of blood and bone marrow to sulfanilamide. J. T. Paul and L. R. Limarzi. *Proc. Soc. Exptl. Biol. Med.* **43**, 29–32(1940).—Therapeutic doses of sulfanilamide commonly produce a mild macrocytic anemia and a normoblastic bone-marrow reaction. Occasionally an acute hemolytic anemia is produced which may be fatal. L. E. Gilson

Effects of atropine and fat on gastric secretion stimulated by alcohol. John S. Gray and Wm. H. Bachrach. *Proc. Soc. Exptl. Biol. Med.* **43**, 36–8(1940).—In dogs with Pavlov pouches the gastric secretory response to dil. EtOH is resistant to the inhibitory effects of atropine or olive oil. L. E. Gilson

Inhibition of experimental dental caries by fluorine in the absence of saliva. Virgil D. Cheyne. *Proc. Soc. Exptl. Biol. Med.* **43**, 58–61(1940); cf. *C. A.* **34**, 809[7].—Removal of the salivary glands from rats 22 days old caused a large increase in dental caries during the next 7 months. Daily administration of 3 mg. F (as KF) by mouth decreased the incidence of caries in the treated group 80–85%. L. E. Gilson

Effect of metrazole on recent learning. Eugene Ziskind, Robert Loken and J. A. Gengerelli. *Proc. Soc. Exptl. Biol. Med.* **43**, 64–5(1940).—Preliminary expts. indicate that metrazole impairs the memory of recently acquired learning. L. E. Gilson

Immediate reactions, to anhydrides, of wheal-and-erythema type. J. L. Jacobs, T. S. Golden and J. J. Kelley. *Proc. Soc. Exptl. Biol. Med.* **43**, 74–7(1940).—Guinea pigs are readily sensitized to citraconic, phthalic, 3-nitrophthalic and *n*-caproic anhydrides. The sensitization is specific for the anhydride used. Citraconic anhydride is the most active. L. E. Gilson

Effect of exercise on growth and cataract development of rats fed galactose. Helen S. Mitchell and Gladys M. Cook. *Proc. Soc. Exptl. Biol. Med.* **43**, 85–6(1940); cf. *C. A.* **32**, 6331[1].—Rats fed rations contg. 25% galactose always show galactosuria and high blood galactose and develop cataract. Exercise in revolving cages delayed cataract but did not affect growth rate or the blood and urine levels of galactose. L. E. Gilson

Oral and parenteral toxicity of vitamin K_1, phthiocol and 2-methyl-1,4-naphthoquinone. Hans Molitor and Harry J. Robinson. *Proc. Soc. Exptl. Biol. Med.* **43**, 125–8(1940).—The oral median lethal dose for mice is about 0.2 g./kg. for phthiocol and 0.5 g./kg. for 2-methyl-1,4-naphthoquinone. Single doses of vitamin K_1 up to 25 g./kg. produced no toxic symptoms. In chronic expts.

on young rats daily feeding of 0.35 g./kg. of phthiocol or 0.5 g./kg. of the methylnaphthoquinone caused death in less than 30 days, while smaller doses produced a marked fall in erythrocyte count. The growth curve was not affected. K_1, 0.35–2.0 g./kg. daily, had no injurious effect. When K_1 was injected intraperitoneally in oil soln. absorption was extremely slow. L. E. Gilson

Plasma electrolytes as affected by insulin and by varying partial pressures of atmospheric gases. Mildred R. Ziegler. *Proc. Soc. Exptl. Biol. Med.* **43**, 165–7(1940); cf. *C. A.* **33**, 7385[5], 8790[8].—Effects of breathing an atm. contg. 5% O and 95% N and one contg. 15% CO_2, 20% O and 65% N, with and without previous injection of insulin, on the blood glucose, proteins, CO_2, P, Cl, Na, K, Ca and Mg of dogs were detd. No definite relation between changes in the electrolyte pattern and the occurrence of insulin convulsions was found. L. E. Gilson

Influence of specific serum therapy on plasma lipides in pneumonia. Albert V. Stoesser. *Proc. Soc. Exptl. Biol. Med.* **43**, 168–70(1940). **Influence of sulfapyridine therapy on plasma lipides in pneumonia.** *Ibid.* 201–3.—Preliminary notes. L. E. Gilson

Experimental evaluation of sulfanilamide derivatives. Hans Molitor. *Merck Rept.* **48**, No. 3, 24–7(1939).—The various factors to be considered are discussed and interpreted in the light of results obtained with sulfanilamide, benzylsulfanilamide and sulfapyridine. S. W. Goldstein

Calcium cyanamide poisoning. E. Mellinghoff and D. Thomas. *Deut. med. Wochschr.* **65**, 1636–7(1939).—A detailed description of a case with clinical history and speculation as to the mechanism of the toxicology. A. G.

Poisoning with lead tetraethyl and its treatment. W. Laves. *Deut. med. Wochschr.* **65**, 1746–8(1939).—The disappearance of the vitamin B complex from the organism in lead poisoning suggested the therapeutic use of these vitamins. The symptoms in dogs poisoned by $Pb(C_2H_5)_4$ were ameliorated or prevented by the use of a liver concentrate rich in the vitamin B complex. Arthur Grollman

Effect of ethyl ether on cholesterol metabolism. G. Pennetta. *Boll. soc. ital. biol. sper.* **14**, 597(1939).—After a tolerance test with cholesterol, the titer in the blood increased during the first $1/2$ hr. with subsequent rapid fall. After injection of Et_2O there were practically the same alterations for the first $1/2$ hr. Subsequent values in general remained high for a longer period. H. L. G.

Pharmacological actions of the venom of Latrodectus indistinctus. H. A. Shapiro, N. Sapeika and M. H. Finlayson. *S. African J. Med. Sci.* **4**, No. 1–2, 10–17 (1939).—Expts. with the venom of *Latrodectus indistinctus* were performed on frogs, rabbits and cats. A perfusion of the isolated heart of *Xenopus laevis* with varying concns. of the venom produced a gradual diminution in the heart beat. With a concn. of the venom of 1:6000 the beats generally became smaller and slower and the heart stopped in mid-diastole. In the intact animal death occurred after 24–30 hrs., with the heart in systolic arrest similar to the effect produced by digitalis. In these expts. 1.0–3.0 mg. of venom was injected into the ventral lymph sac of frogs weighing 21–25 g. each. The effects observed with 26 rabbits and 29 cats were similar in both species, but they appeared to be more const. and pronounced in rabbits. The venom depressed the respiration and the heart and its conducting tissues. It produced a rise in blood pressure with an increase in intestinal and skin vol. The plain muscle of the small intestine and of the pregnant uterus was stimulated. The possibility that the venom produces its effects by the release of a histamine-like substance in the tissues of the injected animal is discussed. The venom itself was not found to contain any detectable traces of histamine or histamine-like substances as tested on the virgin uterus of the immature guinea pig. Five references. W. R. Henn

Changes in the speed of circulation after paralysis of the vagus by large doses of atropine and the relation to neurovegetative tonus in man. Čedomil Plavsic. *Arch. maladies coeur vaisseaux* **32**, 163–74(1939).—Of 26 human subjects given 2.5–3 mg. atropine intravenously, 16 showed an acceleration and 10 a retardation of circulation. Various hypotheses explaining these results are discussed. M. Horn

Action of acids, especially carbonic acid, on the coronary circulation. G. Berthier and P. Gley. *Arch. maladies coeur vaisseaux* **32**, 379–85, 411–18(1939).—Coronary vasodilatation in the isolated rabbit heart was produced by addn. of acids to Locke's perfusing soln. in concns. sufficient to bring the pH to 6.5. The acids used in descending order of vasodilator effectiveness were: carbonic, phosphoric, tartaric and citric. The results explain the beneficial effect of CO_2-yielding baths in patients with coronary disease. Marion Horn

The action of theophylline-ethylenediamine on the intra-arterial pressure of man. Jean Lequime and Jean van Heerswynghels. *Arch. maladies coeur vaisseaux* **32**, 879–86(1939).—In normal and hypertensive human subjects, intravenous injection of 0.480 g. theophylline-ethylenediamine in 20 cc. physiol. saline during 1 min. led to a hypertensive and then a hypotensive phase. The return to the initial pressure occurred in 3 min. in the normal subjects, but was much slower in the hypertensive subjects. Marion Horn

Increasing the rate of excretion of selenium from selenized animals by the administration of *p*-bromobenzene. Alvin L. Moxon, A. E. Schaefer, H. A. Lardy, K. P. DuBois and O. E. Olson. *J. Biol. Chem.* **132**, 785–6 (1940).—Expts. conducted on dogs fed a diet contg. 10 p. p. m. of Se in the form of seleniferous corn and on steers grazing on a seleniferous range indicate that the rate of Se excretion is greatly increased by administration of *p*-bromobenzene. After administering the compd. for 14 days to steers showing typical symptoms of Se poisoning, no Se could be detected in protein-free filtrates of blood and the total Se content of the blood was accounted for by analysis of the blood protein ppt. The *p*-bromobenzene appears to aid the organism in excreting the Se by taking it from the proteins of the blood and tissues possibly as Se-cystine and methionine which are conjugated with it and excreted as the mercapturic acid. The compd. has recently been used with excellent results in the treatment of a human case of Se poisoning. A. P. Lothrop

The modes of lymphogogic action of histamine on the thoracic duct lymph. Hidemasa Yamasaki. *Folia Pharmacol. Japon.* **27** (Opera Orig. 35–56)(1939).—In dogs histamine injected into a systemic vein caused a max. flow of lymph in 10 min. and return to normal in about 1 hr. The protein concn. increased more or less parallel with the flow; blood serum protein decreased. Blood pressure fell rapidly, but portal blood pressure rose; the latter continued high for about 15 min. and then fell gradually. The increase in femoral blood pressure was much less. Injection into the portal vein caused a much more rapid increase in portal blood pressure and less fall in arterial pressure. Little histamine effect on lymph flow was observed when the portal lymphatics were ligatured before injection. Mech. obstruction of hepatic veins, together with the inferior vena cava produced much the same effect as injection of histamine. It appears that under histamine the increased flow from the thoracic duct was due to the production of liver lymph due to an increased blood pressure in liver capillaries and rapid filtration through the endothelium. G. H. W. Lucas

The actions of some new nonalkaloidal antispasmodics on the plain and leech muscle described and compared with those of atropine and papaverine. III. The actions on rabbit intestine in situ and on bronchial spasm. Tadamitu Yosida. *Folia Pharmacol. Japon.* **27**, 294–303 (Breviaria 57)(1939); cf. *C. A.* **33**, 8808[8]; **34**, 819[4].—The effects of octinum, trasentin, B-Tr and B-O were much the same as on excised tissue. Respiration was increased slightly but only in large doses. Trasentin, in acetylcholine spasm of the bronchus, in a limited dose exhibited some antispasmodic effect, but atropine and papaverine regularly produced inhibitory effects. G. H. W. Lucas

The central action of adrenaline on intestinal movement. Hisahumi Hukuhara. *Folia Pharmacol. Japon.*

27, 304–14 (Breviaria 58) (1939).—Various expts. pointed to a central control of intestinal movement when adrenaline was injected. The injection of 0.01 mg. into the 4th ventricle, which produced similar reactions in intestinal movements, demonstrated that the primary action of adrenaline is central. G. H. W. Lucas

Experimental studies on the narcotic action of optical isomers. Kotobuki Hano. *Folia Pharmacol. Japon.* 27, 315–23 (Breviaria 58–9) (1939).—Expts. with secondary butyl alcs. showed that the anesthetic effect of the *l*-isomer was much stronger than that of the *d*-isomer on tadpoles, while the oil-water partition coeff. was the same for both. G. H. W. Lucas

A preliminary study of the anthelmintic activity in vitro of fresh pineapple juice. Conrado F. Asenjo. *J. Am. Pharm. Assoc.* 29, 8–10 (1940).—Fresh pineapple juice digests parasites *in vitro*. The time required for visible signs of digestion to take place is from 3 to 4 hrs. Digestion takes place on the live parasite. The juice maintains its digestive activity on *Ascaris* at a concn. of 15%. A temp. of 65° or over inactivates the enzyme present in the juice. Juice from Cuban, Puerto Rican and Mexican pineapples exhibits the same digestive activity on parasites *in vitro*. Canned juice has no digestive activity on parasites.
A. Papineau-Couture

The transient antidiabetogenic effect of synthetic adrenal cortical hormone: cortate. Preliminary observations. E. B. Winnett, John W. Caldwell and James E. Kahler. *J. Iowa State Med. Soc.* 30, 45–8 (1940).—In daily doses of 15–30 mg., desoxycorticosterone acetate (cortate) was markedly but only transiently hypoglucemic in 2 cases of severe diabetes, necessitating reduction in the amt. of insulin tolerated. This result is directly opposite to that obtained in diabetic animals (cf. Long and Lukens, *C. A.* 30, 3511[2]; Lukens and Dohan, *C. A.* 32, 1782[6]).
J. Pinchack

Prevention of recurrence of urinary stone; chemical analysis; tests for solubility in various hydrotropic and solvent solutions. Walter M. Kearns. *Urologic and Cutaneous Rev.* 44, 86–9 (1940).—A comparison is made of the solubilizing action of 0.5–1% lactic, phosphoric, acetic, succinic and hippuric (0.2%) acids, and of 0.5% Mg or Na salicylate, Na mandelate, Na citrate and Na benzoate on various urinary stones. These compds. were tested alone, dissolved in water or in various combinations with each other. Because of its strong affinity for Ca with which it forms the readily sol. Ca lactate, lactic acid is recommended in urinary lithiasis, especially where there is preponderance of Ca and satn. with phosphoric radical. Where Ca pptn. does not predominate, phosphoric and acetic acids have superior solvent action to lactic acid.
J. Pinchack

Influence of anticoagulants on the different elements of the blood. V. Chorine. *Ann. inst. Pasteur* 63, 367–99 (1939); cf. *C. A.* 34, 1371[1].—Anticoagulants such as oxalate, citrate, fluoride, heparin and hirudin cause a diminution of protein and glucose in the blood plasma of the human subjects and different animals used. This diminution is not due to a pptn. of the proteins by the anticoagulants, but to the diln. of the plasma by the H_2O from the erythrocytes. It is the scpn. of H_2CO_3 from the blood which controls the passage of globular H_2O into the medium at the moment of coagulation. Benjamin Prescott

Research on some synthetic bases antagonistic to histamine. Anne-Marie Staub. *Ann. inst. Pasteur* 63, 485–524 (1939).—2-Isopropyl-5-methylphenoxyethyldiethylamine (F 929) and *N'*-phenyl-*N'*-ethyl-*N*,*N*-diethylethylenediamine (1571 F) antagonize the action of 3 to 5 lethal doses of histamine. Addn. products of these compds. with methylphenyl, dimethylphenyl and isopropylmethylphenyl added on have the same action. The antagonistic action of these compds. is not only on histamine shock but also on the excitations provoked by histamine on the smooth muscles of the intestine, stomach, uterus and bronchioles. This antihistamine action is due to a spasmolytic action and not to a parasympathetic action. Benjamin Prescott

Experiences with Pervitin. Erich Neumann. *Münch. med. Wochschr.* 86, 1266–7 (1939).—Pervitin, 1-phenyl-2-methylaminopropane, has an analeptic action (cf. Füllen, *C. A.* 34, 170[3]). Unfavorable side reactions occurring after administration of large doses of this drug included constipation, increased secretion of sweat, palpitation of the heart and insomnia. Maurice M. Rath

Effect of infusion with gum arabic solutions and blood transfusion on glomerular filtration and tubular reabsorption in healthy and cantharidin-treated rabbits. Makoto Koiwa. *Tôhoku J. Exptl. Med.* 37, 139–62 (1939).—Physiol. salt soln., isotonic (6%) and hypertonic (12%) gum arabic solns. and blood (20 cc. of each substance per kg. body wt.) were intravenously infused into healthy rabbits as well as rabbits whose kidneys had been injured by cantharidin. Glomerular filtration and tubular reabsorption were studied by the method of Nakazawa and Kusakari (cf. *C. A.* 25, 1555). In healthy rabbits, NaCl caused an appreciable diuresis (quantity of urine in 1st hr. increased 49% on the av.) due to increase in the rate of glomerular filtration; 6% gum soln. caused a greater diuresis (59% on the av.) due mostly to an increased rate of glomerular filtration and, partly, to a relative decrease in tubular reabsorption; 12% gum soln. caused a marked increase in diuresis due to a marked increase in filtration (74.9% on the av.) and definite inhibition of reabsorption. In cantharidin-injured animals, the quantity of urine excreted in the 1st hr. decreased 57% on the av. The amt. of glomerular filtration decreased 63.9%. In these rabbits infusion with the various substances, except blood, produced diuresis and an increase in filtration. Compared with healthy animals, this effect was considerably less intense. NaCl, 6% gum soln. and 12% gum soln. caused, on the av., an increased urine excretion of 26, 24 and 63%, resp., in the 1st hr. Blood transfusion had a slight diuretic effect (increase of 21% on the av.) in healthy rabbits which was due mostly to increased glomerular filtration. In cantharidin-treated rabbits, blood transfusion inhibited diuresis, due to a decrease in filtration. Forty-nine references. Maurice M. Rath

Effect of hypnotics and several centrally acting drugs (naphthylamine, picrotoxin) on glomerular filtration and tubular reabsorption. Makoto Koiwa. *Tôhoku J. Exptl. Med.* 37, 163–78 (1939).—Chloral hydrate, 0.15 g. per kg. body wt., subcutaneously injected, increased glomerular filtration 18% on the av. in the 1st hr. after administration, with resultant diuresis. Larger doses (0.3 g. per kg. body wt.) decreased urinary excretion about 58 and 62% on the av. in the 1st and 2nd hrs., resp., and decreased the rate of glomerular filtration 62 and 66.7% on the av. in the 1st and 2nd hrs., resp. Barbital (2 cc. of a 10% soln. of the Na salt per kg.) decreased the quantity of urine excreted on the av. 48 and 56% in the 1st and 2nd hrs., resp.; this amt. correspondingly decreased the rate of filtration 51.2 and 56%. Phenobarbital (Na salt) in doses of 0.1 g. per kg. body wt. inhibited diuresis 54 and 66% on the av. in the 1st and 2nd hrs., resp. These hypnotics act to reduce the blood pressure and slow up the general circulation. Consequently the blood flow through the kidneys is diminished and glomerular filtration reduced. Picrotoxin (1 cc. of a 1% soln. per kg. body wt.) diminished the urine output 40–70% in the 1st hr. and 28–70% in the 2nd hr. Tetrahydro-β-naphthylamine (0.2 cc. of a 5% aq. soln. per kg. body wt.) generally diminished urine excretion. These 2 drugs stimulate the sympathetic nervous system centrally and effect constriction of the renal blood vessels. Forty-six references. M. M. R.

Comparison of different preparations of amorphous and zinc crystalline insulin. Frederick M. Allen. *Endocrinology* 26, 208–17 (1940).—The duration of the effect of any kind of insulin and the differences between different kinds are not abs. but are proportionate to the size of the dose. Testing for duration differs from the usual method of testing potency, in that the clearest results require large rather than small doses. Differences between different brands of amorphous insulin, heretofore supposed to be identical, are clearly revealed by the convulsive method. No consistent differences were shown between different brands of cryst. insulin. The method of blood-

sugar curves in normal and diabetic animals and patients is more delicate, in that it confirms the above-mentioned differences and also reveals others. Different durations of action are thus demonstrated for the amorphous and cryst. insulin prepns. of the same and different manufacturers. The cryst. insulin prepns. as a group have a more prolonged action than the amorphous prepns. The prolonged action of cryst. Zn insulin appears sometimes to be a retarded action, especially with small doses, but more commonly and typically the fall of blood sugar is as rapid and early as with amorphous insulin. The prolonged action thus results in a greater total effect. Protamine Zn insulin is characterized by a long delay in the beginning of its effect in addn. to the extremely long continuance. F. S.

Sojourn of insulin in the blood of rabbits after the administration of massive doses of insulin. Leonard F. Jourdonais and Maurice Bruger. *Endocrinology* **26**, 250–4(1940).—Insulin injected intravenously in massive doses (1000 units) into rabbits was recovered from the blood stream 60–90 min. after the injection. After this time insulin cannot be recovered from the blood by the procedure used, although the insulin effect as demonstrated by hypoglucemia persists for as long as 9 hrs. The largest recoveries of insulin are secured within the first 15 min. after injection. Blood exts. prepd. 75 min. after injection of massive doses of insulin frequently give a hyperglucemic response. In 4 rabbits this massive dose of insulin causes a gradual and persistent rise of blood sugar. The usual hypoglucemic effect of insulin is not evident. These animals die in convulsive seizures not unlike those seen in insulin shock in spite of very high blood sugars. Five rabbits showed only a transient hyperglucemia lasting approx. 1 hr. Evidence is presented to indicate that massive doses may so disturb carbohydrate metabolism as to result in ketosis. Felix Saunders

Toxicology of the linseed plant (Linum usitatissimum Linn). K. N. Bagchi and H. D. Ganguly. *Indian J. Vet. Sci.* **9**, 61–6(1939).—Linseed flowers with immature seeds contain much more HCN than any other parts of the plant, as high as 0.69%. The max. amt. of HCN is liberated in a neutral medium in 4 hrs. Liberation is retarded by dil. and stopped by *N* acids and alkalies. One-half lb. of the flowers will cause death in a bullock, a common occurrence in some parts of India. Na_2CO_3 is recommended as an antidote. J. T. Sullivan

Therapeutic value of wet dressings as tested by hydrogen-ion concentration of inflammatory tissues. Renzo Masuda. *J. Chosen Med. Assoc.* **29**, 1907–18(German abstr., 123)(1939).—Both hot and cold wet dressings have the power to reduce H-ion concn. of inflammatory skin of rabbits (caused by *Staphylococcus pyogenes aureus* or by turpentine oil) to the normal level if the H-ion concn. of the tissue is greater than that of the normal tissue. The cold dressing brings it down to normal faster than the hot, and ice dressing often reduces it below normal. S. T.

Reflex cardiac acceleration and liberation of sympathomimetic substances in unanesthetized dogs during acetylcholine hypotension. W. B. Youmans, K. W. Aumann, H. F. Hancy and F. Wynia. *Am. J. Physiol.* **128**, 467–74(1940). E. D. Walter

Sodium salt of 2-methyl-1,4-naphthohydroquinone diphosphoric acid ester. R. H. K. Foster, John Lee and Ulrich V. Solmssen. *J. Am. Chem. Soc.* **62**, 453–4(1940); cf. Fieser and Fry, *C. A.* **34**, 1649[8].—The Na salt of 2-methyl-1,4-naphthohydroquinonediphosphoric acid ester in doses of 0.6 to 0.8 γ per chick administered subcutaneously reduces the clotting time to below 10 min.; intravenously, it shows similar activity, while the dose for oral effectiveness lies below 2 γ. The lethal dose in mice by both subcutaneous and intravenous administration is approx. 450 mg./kg. C. J. West

The stimulating action of quinine [on smooth muscle] caused by the suppression of inhibition. E. Starkenstein. *Arch. intern. pharmacodynamie* **62**, 146–67(1939).—A theoretical discussion. M. L. C. Bernheim

Histo-biological investigations on the toxic action and elimination of gelsemium. Antonio Risi. *Z. Biol.* **99**, 446–56(1939).—A hypodermic dose of 0.51 mg. gelsemium-HCl killed a rabbit in 16 hrs., paralyzing respiration and reducing heart action and body temp. Introduced into the conjunctival sac, gelsemium caused dilation of the pupils. In the kidneys, it caused microvacuolization and swelling of the tubule epithelium. Injury to the liver resulted primarily in damage to the nuclei and plasma. Gelsemium is excreted partly as such and partly as gelsemic acid. Frances Krasnow

A new preanesthetic, "preanest," and a new anesthetic, "novanest." The Dogliotti-Giordanengo apparatus for general anesthesia. Guglielmo Giordanengo. *Anesthesia and Analgesia* **18**, 251–8(1939).—Preanest is a mixt. of scopolamine bromide, bromides of the total alkaloids of opium and a hypertonic soln. of NaBr. It is administered intravenously about ¾ hr. before operative procedures begin. Novanest is a mixt. contg. Et_2O, chloromethyl ethyl ether, methyl and ethyl chlorides. It boils at 40°. It produces anesthesia rapidly when inhaled in small amt.; recovery is rapid; after-effects are stated to be negligible. G. H. W. Lucas

Anticoagulating power in vivo of sodium polyacetylenedihydroxysulfonate. E. Ferrarini. *Boll. soc. ital. biol. sper.* **14**, 414–16(1939).—Doses of 20–25 mg./kg. acted as good anticoagulating agents for about 2 hrs. after intravenous injection. Helen Lee Gruehl

Occurrence of As in soils and waters in the Waiotapu Valley and its relation to stock health (Grimmett, McIntosh) **15**.

Flavin (vitamin B_2) of the chrysalis of the domestic silkworm. I. Flavin content. Mizuho Sumi and Ziro Tuzuki. *Bull. Inst. Phys. Chem. Research* (Tokyo) **17**, 864–70(1938).—Chem. and biol. tests indicate a very high flavin content, the biol. effect being the same as that of lactoflavin. B. C. P. A.

Structure and function of the excretion system of paramecium. Gábor v. Gelei. *Arch. Protistenk.* **92**, 384–400(1939).—The excretion app. is stained as effectively with sublimate-trichloroacetic acid-2,3,4-trihydroxybenzoic acid and complex org. Ag compds. as by the ascorbic acid-Ag method of J. v. Gelei (*Ibid.* **64**, 479–94 (1928)). The individual sections of the organs are clearly differentiated by these methods. The change in the sol-gel state in the walls of the vacuoles and ampullae has been confirmed and explained on the basis of the staining with Ag. Ruth Berggren

Comparative actions of potassium and acetylcholine on the muscles of the toad. V. H. Cicardo. *Compt. rend. soc. biol.* **132**, 505–7(1939).—See *C. A.* **33**, 7903[7]. L. E. Gilson

Influence of light and darkness on the melanophore-dilating activity of the hypophysis [of toads]. Julio N. Masselin. *Compt. rend. soc. biol.* **132**, 511–13(1939).—See *C. A.* **33**, 7903[9]. L. E. Gilson

Effect of carbon dioxide on glucose metabolism of trypanosomes. D. S. Searle and L. Reiner. *Proc. Soc. Exptl. Biol. Med.* **43**, 80–2(1940).—Preliminary. L. E. Gilson

The reproduction of Xenopus laevis. II. The histological changes in the accessory sex organs of female Xenopus induced by the administration of endocrine preparations. L. Berk and H. A. Shapiro. *S. African J. Med. Sci.*, Feb., Suppl. to Vol. 4, 13–17(1939); cf. *C. A.* **33**, 8828[8].—All expts. were performed on females recently brought in from ponds and whose lab. age did not exceed 2 weeks. The skin and the oviducts of *Xenopus laevis* are described and the presence of saccular glands in the skin is confirmed. The cloacal labia characteristics of the female are a modification of the skin. The activation of the labia and of the oviducts by gonadotropic substances consists in the production of a capillary congestion. This hyperemia of the cloacal labia was used as a test for the detection of gonado-

tropic substances. The gonadotropic activity was demonstrated in exts. of human pregnancy urine and of bovine and sheep anterior pituitary. Implanted *Xenopus* anterior lobes and injected steroids (methyltestosterone, testosterone propionate and progesterone) also exhibited gonadotropic properties. Implanted dogfish anterior pituitaries (in the doses given) did not appear to be gonadotropic in *Xenopus laevis*. Eleven references. III. **The secondary sex characters of the male Xenopus: the pads.** Lionel Berk. *Ibid.*, 4, No. 3, 47–60.—The cyclical development of pads on the forelimbs of *Xenopus* males appears to be under the control of the anterior pituitary acting through the testis. Pad development can be induced at all times of the year in *Xenopus* males by the injection of anterior pituitary prepns. There is no species or sex specificity in this action of the anterior pituitary. The distinctive manner in which the pads develop is described both macroscopically and histologically. Captivity in *Xenopus laevis* prevents the release of anterior pituitary gonadotropic principles into the circulation. Methyl testosterone and testosterone propionate are inactive in *Xenopus* males. The *Xenopus* testis hormone probably differs from the mammalian testis hormone. The pads of *Xenopus* males have at the most only a minor functional significance. Twenty-four references. W. R. Henn

Ovulation in Xenopus laevis induced by certain steroids. H. A. Shapiro. *S. African J. Med. Sci.*, Feb., Suppl. to Vol. 4, 21-31(1939).—The 10 substances which stimulated ovulation in *Xenopus laevis* (S. African clawed toad) fall into 2 distinct but chemically related steroid groups: members of the androstane series and members of the pregnane series. No substance showed activity if the side-chain at C_{17} was longer than that occurring in the pregnane series; if the compd. was unsatd. saturation destroyed gonadotropic activity, ethylation destroyed activity, the methylated form of the hormone possessed increased gonadotropic activity and esterification diminished, destroyed or delayed activity; compds. having a hydroxyl group at C_3 were active whereas their isomers were inactive and the trans position of H at C_5 can confer gonadotropic activity. None of these active steroids was of pituitary origin. There was no specific configuration of the steroid mol. which can be associated with its gonadotropic properties in *Xenopus laevis*. The long side-chains at C_{17} appeared to destroy gonadotropic activity; the most active compds. were associated with a Δ^4-3 keto constitution, the steroids were also active in the hypophysectomized animals and the gonadotropic properties of these steroids did not appear to have a general application to the amphibia. Eight references. W. R. Henn

The influence of the electrolyte content of the water on water animals at higher temperatures. E. Merker. *Naturwissenschaften* 27, 786–7(1939).—Whereas at 20° the salt content (especially Ca) of water protects soft-skinned animals against short-wave light (*C. A.* 33, 8317[8]) this effect disappears at 1–5°; resistance to the light is then afforded by both salt-free and salt-contg. water. Similarly it was found that increased salt concn. protects these animals against the effect of heat to some extent. Freshwater crabs which died at 29° in salt-free water, lived for less than 15 min. at 32° in water of 7 mg. Ca per l., lived 15 min. at 33° in water of 50 mg. Ca per l. In salt-free water Na and Ca from the body of the animal appears in the water after 1 hr. Animals pretreated in cold salt-free water show even less resistance at high temp.
B. J. C. van der Hoeven

Effect of vitamin D on the growth and propagation of Gambusia aff. holbrookii. G. V. Samokhvalova. *Compt. rend. acad. sci. U. R. S. S.* 24, 609–12(1939)(in English).—*Gambusia* (a fish destroying mosquito larvae) reared under aquarium conditions are undeveloped. Sunlight is one of the basic factors detg. normal growth and propagation. Ultraviolet light produces vitamin D in the organism. By supplementing the food with vitamin D, growth, sexual maturity and propagation of the fish are promoted. A. H. K.

The metabolism of the egg and embryo in amphibians. III. The absorption of oxygen in the primary organ center of Bufo vulgaris and Rana esculenta. Alberto Stefanelli. *Arch. fisiol.* 39, 176–209(1939); cf. *C. A.* 34, 175[8].

A hormone which induces pupation in the common housefly, Musca domestica Linn. Paul DeBach. *Ann. Entomol. Soc. Am.* 32, 743–6(1939).—True hormones are found in insects and a new field of insect endocrinology is developing. Expts. showed that pupation of the housefly is initiated by a hormone secreted in the region of the "ganglion" of Hewitt (cf. The House-fly, Cambridge Univ. Press, 1914). The chem. nature of the hormone was not detd. The literature of the subject is reviewed.
C. H. Richardson

The nature of the secretory activity of the isolated Ringer-perfused frog liver. I. The differential secretion of pairs of dyestuffs. Rudolf Höber. *J. Gen. Physiol.* 32, 185–90(1939).—The perfused liver of *Rana temporaria* and *R. pipiens* is able to conc. in its secretion a large no. of dyes. The concn. attained may range from several hundred- to a thousandfold. When 2 dyes are perfused simultaneously, the liver seps. them, sometimes to such an extent that one compd. is suppressed entirely by the other. Secretion, under these conditions, depends upon the adsorbability of the dye rather than upon its diffusibility or lipoid soly. This is concluded from unpublished studies on perfused frog kidney which show that only dyes with a polar-nonpolar mol. configuration can pass through the kidney tubule wall. At the interface between cell and its surroundings, the dye is probably first anchored to one medium by the hydrophilic polar part of the mol., and to the other medium by the organophilic nonpolar part of the mol. While expts. of this nature have not yet been made on the liver, the operation of a similar mechanism is suggested by the failure of the perfused liver to secrete dyes having a large no. (4–5) of hydrophilic sulfonic acid groups. II. **The inhibitory and the promoting influence of organic electrolytes and nonelectrolytes on the secretion of dyestuffs.** Rudolf Höber and Elinor Moore. *Ibid.* 191–202.—The ability of the perfused frog liver to conc. dyes can be abolished entirely and reversibly by replacing about 1/8 of the NaCl in the Ringer soln. by an isosmotic amt. of a surface-inactive nonelectrolyte(disaccharide, hexose, pentose, polyhydric alc., amino acid, acid amide) or electrolyte; the effect is not dependent on changes in the diffusion rate. The opposite effect, i. e., promotion of secretory activity, is produced by polar-nonpolar electrolytes (bile salts, aromatic sulfonic acids) and by surface-active nonelectrolytes (anesthetics, alkaloids). Reversibility of this effect cannot regularly be observed on account of frequent cytolysis. Suitable concns. of inhibitory and promoting substances applied simultaneously counteract each other; inhibitory and promoting substances exhibit opposite effects on the dispersion of colloids. Since the promoting substances show a polar-nonpolar mol. configuration, the hydrophobic part of the mol. can adhere to org. substances, the hydrophilic part pulling toward water and exerting a loosening and swelling effect. However, among promoting substances are also found more or less apolar compds. which, because of their organophilic character, penetrate lipoidal structures, changing the intermol. adhesive forces and counteracting the close mol. packing with disintegration as the final result. Between these two groups are intermediate substances with slight hydroaffinity(ethylene glycol, glycerol) or slight organotropy(acetamide, urea). C. H. Richardson

Rod and cone electroretinograms in relation to pigment migration in normal and adrenalized frogs. P. O. Therman. *J. Cellular Comp. Physiol.* 14, 253–9(1939).—The elec. response of the frog retina (*b*-wave) to a standard red and a standard blue stimulus was measured. Adrenaline acts the same as light adaptation in that it expands the pigment and causes cone contraction. These changes were confirmed histologically and occur without any equiv. changes in the retinal elec. response or in the blue/red ratio. The protective role of the pigment epithelium must be negligible. Felix Saunders

Effects of calcium and magnesium on metabolic processes in Chilomonas paramecium. S. O. Mast and D. M. Pace. *J. Cellular Comp. Physiol.* **14**, 261–79(1939).—*Ch. paramecium* grows and reproduces indefinitely in isolation cultures in a soln. which consists of NaOAc, NH_4Cl, K_2HPO_4, $MgSO_4$ and water if the soln. is changed daily. If Mg is omitted from the soln. the culture dies out in a few days. If Ca is substituted for Mg and the soln. changed daily, growth and reproduction continue indefinitely, but the optimum concn. for Ca is lower than that for Mg. If both Mg and Ca are present and the concn. of the Ca is 0.001 *M*, the optimum concn. for Mg is 0.0001 *M* instead of 0.001 *M* and the rate of reproduction at the optimum is considerably higher than it is when either of the 2 is present without the other and the cultures live longer. Absence of Ca and Mg inhibits division of the cytoplasm but it does not inhibit synthesis of starch and fat and it does not prevent division of the nucleus. As a result, multinucleate monsters are formed which die in a few days. If these monsters are not too complicated they divide and become normal if Mg or Ca is added to the culture soln. Felix Saunders 1

Oxidative control of "spontaneous" activity in the nervous system of the crayfish. C. Ladd Prosser and Clara C. Buehl. *J. Cellular Comp. Physiol.* **14**, 287–97 (1939).—The spontaneous activity of isolated groups of abdominal ganglia of the crayfish requires an adequate O supply. NaCN in low concns. initially stimulates and later depresses the spontaneous activity. As the cyanide concn. increases, the depressing effect comes earlier. The effect of cyanide is greater upon isolated ganglia than upon those ganglia when the nerve cord is intact. A mixt. of CO and O (9:1) reversibly inhibits the spontaneous activity. The inhibition is partly reversed by illumination. Dinitrophenol in very low concns. stimulates, and in higher concns. initially stimulates and then depresses, the spontaneous activity. Na iodoacetate has no effect on spontaneous activity in crayfish ganglia isolated in air. Cyanide and CO exert their effects by altering the no. of spontaneously discharging neurones. Whether or not a neurone fires spontaneously depends on intraganglionic oxidations catalyzed by well-known enzyme systems. Felix Saunders 4

Physiological effects of nitro- and halo-substituted phenols on Arbacia eggs in the presence of ammonia. John O. Hutchens, M. E. Krahl and G. H. A. Clowes. *J. Cellular Comp. Physiol.* **14**, 313–25(1939).—The effects of 2,4-dinitrophenol, 4,6-dinitro-*o*-cresol, 2,4,5-trichlorophenol, 2,4-dichlorophenol and *m*-nitrophenol on the respiration and cell division of fertilized eggs of *A. punctulata* were detd. at const. extracellular pH in presence and absence of a concn. of NH_3 sufficient to increase the cytoplasmic pH from 6.8 to 7.2. The relative and abs. stimulation of O consumption produced by suboptimum concns. of each phenol is greater in the presence than in the absence of NH_3. The relative inhibition of cell division by each concn. of each phenol is the same in the presence and absence of NH_3. The extracellular concn. of total substituted phenol producing the optimum respiratory stimulation is the same for each phenol in the presence and absence of NH_3. Felix Saunders 6

Organic and inorganic electrolytes in lobster nerves. Francis O. Schmitt, Richard S. Bear and Robert H. Silber. *J. Cellular Comp. Physiol.* **14**, 351–6(1939); cf. *C. A.* **34**, 530[3].—Electrolyte analyses of lobster nerves indicate the presence of relatively large quantities of org. anions. After allowing for chloride and other inorg. anions the concn. of org. anions in an aq. ext. is approx. 0.3 milliequiv. per g. of water in the nerves extd. Removal of protein by Cl_3CCO_2H reduces this figure but slightly. Approx. 70% of the N is nonprotein N, amounting on the av. to 5 mg. per g. of nerve extd. Half of this is amino N. The unidentified anion may be an amino acid. F. S. 7

Excretion of phenol red in the dogfish, Squalus acanthias. Willie W. Smith. *J. Cellular Comp. Physiol.* **14**, 357–63(1939); cf. *C. A.* **33**, 7906[4].—Phenol red is copiously secreted by the tubules of the dogfish, the mean clearance of phenol red at plasma levels below 1 mg. percent being 1750 cc. per kg. per day with a phenol red/inulin clearance ratio of 22.6. Max. tubular secretion is reached when the concn. of phenol red in the plasma is about 2 mg. percent. The mean rate of max. tubular secretion is 18 mg. per kg. of fish per day, or 4.8 mg. per g. of kidney per day. Hippuran depresses the rate of tubular secretion of phenol red, but creatinine has no effect. Felix Saunders 8

Electrolytes in squid blood and muscle. Jeanne F. Manery. *J. Cellular Comp. Physiol.* **14**, 365–9(1939).—Squid blood and muscle were analyzed for Na, Cl, K and water, and mantle nerve was analyzed for K and water. The Na/Cl ratio in the muscle is the same as that in blood indicating the presence of a phase similar in compn. to blood. The "chloride space" is 16%. The sum of the Na and K concns. in muscle is equiv. to 0.5 of that of blood. Felix Saunders 2

Secretion of oxygen at high pressure from the blood of fish. Laurence Irving and Stuart W. Grinnell. *J. Cellular Comp. Physiol.* **14**, 409–10(1939).—CO_2 produces a pO_2 which is adequate to inflate the swim bladder of a trout with pure O at a depth of 15 ft. under water. Felix Saunders 3

The birefringent inclusions of the ciliates and cryptomonads. G. Deflandre. *Bull. soc. franç. microscop.* **7**, 110–29(1938).—The literature is reviewed and D's. observations are discussed. The inclusions may be either endogenous or exogenous. Their chem. compn. and physiol. significance seem to be very variable, some may be reserve materials while others are apparently waste products. 22 references. W. C. Tobie

Excretion by cephalopods. Pasquale Bruni. *Pub. staz. zool. Napoli* **16**, 16–27(1937).—Diffusible dyes injected into the musculature of the mantle of *Sepia officinalis* are eliminated by diffusion through the renal app. with the production of polyuria. The elimination of injected colloidal dyes through the renal app. is largely due to phagocytosis by the amebocytes which carry the dye through the epithelium. Elimination continues for 40 hrs. or more. The intensity of the diuresis produced by dyes diminishes in the order: eosin, toluidine, methylene blue. Trypan blue and sepia black produce oliguria. 24 references. W. C. Tobie 5

The relation of the liver to sexual maturity and gestation in selachians. Margarete Falkenheim. *Pub. staz. zool. Napoli* **16**, 212–20(1937)(in Italian).—The relative wt. of the liver and its histological condition were detd. in the females of *Mustelus vulgaris*, *M. laevis*, *Acanthias vulgaris*, *A. blainvillei*, *Centrophorus granulosus* and *Scymnus lichia* at various stages of the sexual cycle. Changes in liver vol. and wt. are due to accumulation or mobilization of lipoids and squalene by the liver cells. In *Mustelus laevis* mobilization occurs at the beginning of gestation and accumulation at its close. 7 references. W. C. Tobie

The dependence of size and shell-thickness of marine molluscs on the temperature and salt content of the water. Chen Ya-Shih. *Sitzber. Ges. naturforsch. Freunde Berlin* 1937, 238–87.—The size and thickness of shell (and to some extent body size) were detd. on 10,952 specimens representing 24 species of prosobranchiate gastropods and mussels from arctic, temperate and tropical seas of varying degrees of salinity. For most species there is an optimum av. annual temp. for max. size. Large fluctuations above and below the av. temp. cause a reduction in size. In many species the prolongation of the growth period caused by lower temps. produces an increase in size of the body, although the shell is lighter and thinner owing to a reduced excretion of $CaCO_3$. Slight changes in salinity usually have no effect on the size of the shell and the body. A reduction of the salinity below 3% inhibits growth of the body and shell, because of metabolic changes. In less saline water *Nucella lapillus* develops a larger kidney which serves to eliminate excess water. The quant. data are tabulated in detail. A tabulation of data from the previous literature is given on the relative sizes of shells of 194 species from the Mediterranean, English and Finnish coasts. 46 references. W. C. Tobie 9

Curtis, Winterton C., and Guthrie, Mary J.: Laboratory Directions in General Zoölogy. London: Chapman and Hall, Ltd. 195 pp. 9s.

12—FOODS

H. A. LEPPER

Preserving the dietetic value of frozen foods. E. M. Chace. *J. Am. Dietet. Assoc.* **16**, 34–8(1940).—A discussion. E. Curzon

Uses of aluminum in the food industries. Antonio Montefredine. *Ind. ital. conserve* **14**, 142–6(1939).—In Italy, where a systematic promotion campaign has been carried on, Al for containers has gained most headway in the dairy industry, as cans for milk, as dairy equipment (pasteurizers, cheese vats, etc.), and as foil wrappers for butter and cheese. Considerable progress has also been made in developing Al containers for oils and fats, fish products and canned vegetables; also in Al foil wrappers for candy and other products. Light wt. and corrosion resistance are major advantages, with ease of recovery favoring economy. 50 references. Julian F. Smith

Aluminum as packing material for the canning industry. G. Lunde. *Aluminium* **21**, 843–5(1939).—Al of 99.5% purity was used in Norway with perfect success for cans for fish products, sardines, shrimps, etc. In general, the Al sheet does not need a treatment (coating) except when acid corrosion is present, as in berries or tomatoes. Neutral fish products and fish in jelly can be kept for years. As Al is much softer than tinplate, the deep-drawability is greater and cans can be drawn better in one process; but because of the softness of the material greater care has to be exerted in sterilizing and pasteurizing that the inner pressure during heating does not crack the cans. Tests to see how much Al had been dissolved in different preserves showed after 24–36 months between 0.5 and 8.6 mg. per 100 g. content, about as much as the amts. found in foods cooked in Al vessels, and perfectly harmless. Products which cannot be canned in 99.5% Al require "eloxated" Al or Al alloys; expts. in this direction are still being made. Six references. M. Hartenheim

Internal lacquering of tinplate containers for foods. I. Determination of tin in foods and a survey of the tin content of some canned foods. L. J. Lynch and J. F. Kefford. *J. Council Sci. Ind. Research* **12**, 303–10(1939).—The Sn content of a series of canned foods marketed in Australia is reported. The results show the need for lacquered containers, particularly for fruit and vegetable juices. Several com. lacquers were shown to be suitable. Spray-lacquering into the made-up can is the most satisfactory method of application. Philip D. Adams

Germicidal properties of paraffin. F. W. Tanner and H. F. Lewis. *Oil and Soap* **17**, 26–30(1940).—The effect of hot paraffin wax on bacteria on food containers under conditions which exist in actual practice was studied. Half-pint milk containers were heavily inoculated with *Escherichia coli* and an aerobic spore-forming species by filling with a heavy suspension of pure cultures and then emptying. It was estd. that each container received over 200,000 bacteria. After drying at 90°F. the paper bottles were paraffined at 74° and 79.5°, drained and cooled at 10–15°. The bottles were examd. by dissecting under aseptic conditions, also by filling with milk and broth and storing at room temp. and at 4.5°. The disintegration tests showed that the bacteria did not survive the treatment. Milk and plain broth from bottles stored at 4.5 and 21° did not yield any *Escherichia coli* and only a few from bottles paraffined at 76.6°. Bottles contg. plain broth were entirely free from the organism. The aerobic spore-forming bacterium was used because it should have survived the treatment and was used as a control, but it was also destroyed. To sterilize paperboard by high pressure steam and then paraffin it gives results of questionable value because the steam changes the nature of the board so that it accepts paraffin in a much different manner. Bibliography. E. Scherubel

Determination of citric acid in food products. K. Rundell. *Soc. Chem. Ind. Victoria, Proc.* **39**, 183–8(1939).—In detg. the citric acid content of food products it is necessary first to ext. the citric acid. The materials which have to be removed are proteins, fats and sugars and this is usually accomplished with the aid of clarifying agents such as phosphotungstic acid. With milk or other samples low in citrate and relatively high in sugars, it is customary to remove the fat and protein by pptn. with phosphotungstic acid and then ppt. the citric acid in the clear filtrate as insol. Pb citrate. Attempts to titrate fairly pure solns. of citric acid potentiometrically with a neutral soln. of $CaCl_2$ proved unsuccessful. The pentabromoacetate method, which depends on the oxidation of citric acid to acetonedicarboxylic acid with $KMnO_4$ in the presence of KBr + H_2SO_4, was next tried. Considerable difficulty was encountered in getting a const. wt. of the final product but by adopting a somewhat modified procedure good results were obtained. To 75 ml. of dil. citric acid soln. add 10 ml. of 18 *N* H_2SO_4 and 5 ml. of KBr, heat to about 50° and after 5 min. at this temp. add 50 ml. of 5% $KMnO_4$ soln. dropwise from a buret. After all the $KMnO_4$ has been added, allow to stand 3 min. and dissolve all MnO_2 from the ppt. by adding about 20 ml. of 20% $FeSO_4$ soln. and shaking. Cool for 4 hrs., filter the soln. through a tared Gooch crucible and use the filtrate for transferring all the ppt. to the filter. Wash with 50 ml. of cold water. Dry in a stream of clean dry air in a vacuum of 20–25 in. and weigh. W. T. H.

Nicotinic acid content of some foods. F. Del Regno. *Quaderni nutris.* **6**, 368–73(1939).—Nicotinic acid occurs very diffusely in nature. Values are high in meats and lowest in vegetables. Actual results of a long list of foods are charted. Helen Lee Gruehl

Vitamins. Paul W. Allen. *Natl. Butter Cheese J.* **31**, No. 1, 16–18(1940).—A review of vitamins in relation to dairy products. A. H. Johnson

The vitamin B_1 content of foods in terms of crystalline thiamin. Lela E. Booher and Eva R. Hartzler. *U. S. Dept. Agr., Tech. Bull.* **707**, 20 pp.(1939).—The most important natural food sources of vitamin B_1 for human dietaries are whole-grain cereals, legumes, nuts, and lean pork, both fresh and cured. Although as much as 50–60% of the vitamin B_1 value in lean pork is ordinarily destroyed as a result of cooking processes, the cooked product is still an excellent source of this vitamin. Fruits in general are not important sources of vitamin B_1. For the most part vegetables other than legumes are fair or unimportant sources of vitamin B_1. 29 references. W. H. Ross

Distribution of vitamin B_1 in foods as determined by chemical analysis. Magnus Pyke. *J. Soc. Chem. Ind.* **58**, 338–40(1939).—A survey of the distribution of vitamin B_1 (I) in 190 samples of food has been carried out by a rapid chem. technique using a modification of Jansen's thiochrome method in which the complete extn. of I is ensured by digestion of the sample with pepsin followed by hydrolysis of the pyrophosphate fraction with takadiastase. The amt. of thiochrome is measured by estg. the intensity of its fluorescence by the visual method of Wang and Harris (*C. A.* 33, 9388[1]). Details of the method are given. The values found are tabulated with 50 values collected by Cowgill and 45 values assembled by Fixsen and Roscoe as detd. by Baker and Wright (*C. A.* 29, 6965[6]) using the rat bradycardia method. I is a dietary constituent of such importance that knowledge of its distribution in foodstuffs is a matter of immediate practical importance. C. R. Addinall

Minerals and vitamins of grains. G. Quaglariello.

Quaderni nutriz. **6**, 276–89(1939).—A discussion summarizing data from the literature. Helen Lee Gruehl

Vitamin content of wheat germ. Darline Knowles. *N. Dakota Agr. Expt. Sta., Bimonthly Bull.* **2**, No. 2, 11–12(1939).—Wheat germ is credited with 1200 Sherman units of vitamin B (undifferentiated) per g. and 300 Sherman-Bourquin units of vitamin G per g. The food is a good source of vitamin E. C. R. Fellers

Quality in rice. III. Digestibilities in vitro of different varieties of rice. A. Sreenivasan and K. Vankata Giri. *Indian J. Agr. Sci.* **9**, 193–207(1939); cf. *C. A.* **33**, 3476[2].—The digestibility of raw or parboiled rice by pancreatic and salivary amylases increases with the degree of polishing. Parboiled rice, especially when unpolished, is more easily digested than raw rice. There is, however, a large amt. of individual variation between varieties. With increase in the degree of polishing there is an increase in the viscosity of the cooked flour and a slight diminution in the extent of hydrolysis of the starch. When the whole grains are cooked the starch is hydrolyzed less easily than raw starch by pancreatic amylase; the rate of hydrolysis is detd. by the extent of penetration of the digestive enzymes into the grain. Rice bran has a definite inhibitory action on amylases which is greatest with the first layer of polishings and decreases steadily with the subsequent layers. Ether-sol. substances and proteins of the bran exercise definite, though small, inhibitory action on starch hydrolysis. IV. **Storage changes in rice after harvest.** A. Sreenivasan. *Ibid.* 208–22.—Stored rice grains swell on cooking to 4 times their original vol. but freshly harvested grains swell to only twice the vol. Increased temp. and reduced air supply during storage improve the cooking quality. A moderate degree of polishing improves the swelling capacity and cooking quality of both unstored and stored rice but a high degree of polishing decreases the swelling capacity of the latter. Expts. *in vitro* indicate that when rice is cooked to a paste it does not digest as much as when cooked to a fluffy consistency. The growth rate of rats fed on cooked powd. rice was less than when fed on cooked whole rice. Starch from well-stored rice is slightly but definitely more easily hydrolyzed than that from freshly harvested rice. During the ripening of the grain there is a steady decrease in reducing and nonreducing sugars and dextrin and a rapid increase in the starch content. During storage there is no change in the various constituents. The resting seed contains both a liquefying (α) and a saccharifying (β) amylase; their activities are greatest at the milk stage and decreases with ripening and during storage of the grain. In the well-stored grain the amylases are dormant and cannot be extd. with water. There is a close parallelism between the decreased activity of the α-amylase during storage and the improvement in swelling capacity on cooking. It is concluded that the pastiness on cooking of unstored rice may be due to the α-amylase; the inactivation of this during storage is followed by increased swelling capacity on cooking. J. T. Sullivan

Quality tests on soft red winter wheats of Kansas. R. K. Larmour, Earl B. Working and C. W. Ofelt. *Cereal Chem.* **17**, 18–28(1940); cf. *C. A.* **34**, 530[8].—Kawvale, a semihard variety, appears to be distinctly differentiated from the typical soft varieties Clarkan, Harvest Queen and Michigan Wonder. These latter 3 varieties were lower in baking quality than either Kawvale or Turkey of comparable protein levels. Baking tests of the soft wheat varieties did not give a linear relation between loaf vol. and protein content; the loaf vol. tends to fall off at about 10% flour protein. Somewhat better relationship of these variables was obtained with 3 mg. $KBrO_3$ and 6% dry milk solids than with 1 mg. $KBrO_3$ and 4% dry milk solids. This would indicate the need for testing the higher-protein soft-wheat flours with greater dosages of bromate. L. H. Bailey

Influence of variety and treatment on phytin content of wheat. Silas M. Young and J. E. Greaves. *Food Research* **5**, 103–8(1940).—Twenty-one samples of wheat grown under different fertilizer treatments were examd. for phytin content by the method of Heubner and Stadler (*C. A.* **8**, 3569). Some of the varieties had twice as much phytin P as others. The lowest content was found in Newturk variety with 0.152%, and the highest in Dicklow with 0.328%. The percentage of phytin P of the total P varied from 56.7% in Regal to 94.3% in Federation. C. R. Fellers

Gluten. C. O. Swanson. *Northwestern Miller* **199**, (4), Sect. 1, 7a(1939).—Gluten and protein are closely related but not synonymous. Not all the protein in flour goes into gluten, nor is gluten as ordinarily obtained, all protein. Dry crude gluten will analyze about 85% protein; the other 15% will be made up of crude fiber, ash, starch, fat and some other substances. Some of the protein of flour is of such nature that it does not form gluten, and the amt. is about the same as other substances in crude gluten; therefore, the amts. of dry crude gluten and protein in flour are about the same. L. H. Bailey

Control dough temperature during fermentation. J. G. Malloch. *Cereal Chem.* **17**, 73–8(1940); cf. *C. A.* **33**, 2597[4].—It was shown that the dough temp. within the fermentation cabinet was not const. When a water bath was substituted for the fermentation cabinet there was some improvement in uniformity. Other features tending to favor uniformity are a water-jacketed mixer, changes in the wiring of the oven, and alterations in the air-conditioning app. to give improved control of temp. L. H. Bailey

Plasticity in doughs. Olof E. Stamberg and C. H Bailey. *Cereal Chem.* **17**, 37–44(1940).—A plastometer of the extrusion type was designed and constructed for use in the study of the plasticity of bread doughs. The app. was so constructed that doughs maintained at a const. temp. were extruded through a 6-mm. aperture from a cylinder by means of air pressure equiv. to 500 mm. of Hg. Rate of flow per min. was used as an index of the relative plasticity of the doughs. It was found that small temp. variations may affect the rate of flow to a greater extent than any probable variation in pressure, thus emphasizing the necessity of precise temp control in making such measurements. The log of the rate of flow was a linear function of the proportion of H_2O to flour used in mixing the dough. L. H. Bailey

Prediction of baking value from measurements of plasticity and extensibility of dough. I. Influence of mixing and molding treatments upon physical dough properties of typical American wheat varieties. Emil Munz and C. W. Brabender. *Cereal Chem.* **17**, 78–100(1940).—It appears important to study the rate and direction of change in dough properties, rather than to measure the dough properties at one stage only. Dough plasticity as a function of mixing treatment is a significant characteristic, but it fails to disclose other important actua or potential properties such as are affected, e. g., by certain chem. treatments. It is not always possible to predict from such measurements made during the initial mixing how far a dough may recover its properties after severe overmixing. Vigorous treatments such as are accorded by mixing, molding and punching effect an "excited condition" in a dough in which condition it exhibits different phys. properties from those shown in a state of relaxation. These induced effects do not remain const., and the dough tends to return to its original state if allowed to stand undisturbed for a time, and the rate and degree of change depend upon the properties of the flour and the treatments to which it, or the dough, has been previously submitted. On extended overmixing, doughs tend to lose extensibility and to increase in resistance to extension on standing. "Optimal mixing time" must be regarded as a relative term, depending upon such factors as the type of mixer employed, nature of fermentation, and chem. treatment accorded the dough. It is not a definite or abs. value, except as thus qualified. L. H. Bailey

The pressuremeter in the study of yeast. J. M. Doty and W. R. Urban. *Cereal Chem.* **17**, 44–54(1940).—A com. pressuremeter (Sandstedt and Blish, *C. A.* **28**, 6490[1]) was used on an unmalted flour to det. the characteristics and uniformity of various com. yeasts. The data obtained under various conditions correlated very well with data ob-

tained by actual test baking both on straight-dough and sponge methods. The pressuremeter shows very marked differences between various com. yeasts, and by proper manipulation it will show certain yeasts more adaptable to certain conditions. If the conditions under which a yeast is to be used are known, the pressuremeter will assist in detg. yeast characteristics that will best be suited to this set of conditions. L. H. Bailey

Effect of storage temperatures upon the viability and baking properties of compressed yeast. Lorin H. Bailey, M. T. Bartram and S. C. Rowe. *Cereal Chem.* **17**, 55–66 (1940).—Compressed yeast packed with dry ice for 2 days was stored along with fresh compressed yeast at 0°, 20°, 30° and 45°F. for 3 months. Microscopical, pH and baking tests were made at the beginning and at the end of one month, 2 months and 3 months, resp., at the temps. indicated above. The yeast that had been packed in dry ice deteriorated more rapidly than the fresh yeast stored for the same length of time and at the same temps The frozen yeast became mushy after it was thawed, making it more difficult to handle. Of the different storage temps. used, 30°F. is considered the most suitable since the yeast did not freeze at that temp., nor lose its normal consistency, and bread made from this yeast was fully equal to that made with yeast stored at any other temp. The temp. of evapg. dry ice (−109°F.) injures yeast in 24 hrs. and subsequent storage below freezing increases the amt. of deterioration. L. H. Bailey

Viscosity measurement in judging the baking quality of flour. Hugo Kühl. *Chem.-Ztg.* **64**, 49–50(1940).—A review with 16 references. E. H.

Bread (analyses). E. M. Bailey. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **426**, 10–11(1939); *43rd Rept. Food Products.*—Fresh white and whole wheat breads (8 samples of each) showed the following av. percentage compn., resp.: moisture 35.92, 36.39; ash 2.28, 2.49; protein 10.58, 11.12; fiber 47.46, 46.34; fat 3.33, 2.65; milk solids 7.31, 7.44. C. R. Fellers

Determination of sugars in bread. M. W. Fuhri Snethlage. *Chem. Weekblad* **37**, 16–19(1940).—Bread prepd. with the addn. of malt or malt ext. must by the present food law in the Netherlands be designated as "maltbread." To det. if malt or malt ext. was used in the baking process, a series of expts. was carried out with different kinds of yeast to sep. the maltose formed from the other sugars normally present in bread or added to it. By using *Saccharomyces fragilis* maltose was left intact in presence of glucose, fructose, lactose, galactose and sucrose. In milkbread *Torula monosa* was used; this leaves maltose and lactose intact. Results are given and tabulated showing maltose and lactose values for different kinds of bread as sold, and of bread prepd. specially with known amts. of ingredients. J. C. Jurrjens

Review of progress in research on bread staling. Wm. H. Cathcart. *Cereal Chem.* **17**, 100–21(1940).—This review attempts to explain what happens when bread stales; it discusses methods of measuring staleness and summarizes methods of preventing staleness. The inadequacy of our present knowledge of what happens when bread stales, the disagreement between phys. or mech. methods and the results of personal judgment as to the rate of bread staling, the lack of much scientific research on the effect of certain processes, ingredients, etc., in preventing bread staling, and the disagreement of existing data make definite conclusions difficult and point to the need for further strictly controlled scientific researches. Some processes, ingredients, etc., have an effect on delaying staleness, while others have little effect, if any at all, and in some cases even decrease bread quality. Many methods recommended for delaying crust staling increase crumb staling and *vice versa*. The two most effective methods for delaying crumb staling are heat and cold, yet these are not entirely practical at the present time. L. H. Bailey

The effect of milk on the bromate requirements of flours. C. W. Ofelt and R. K. Larmour. *Cereal Chem.* **17**, 1–13 (1940).—In general the inclusion of 6% dry-milk solids creates a tolerance toward bromate which tends to prevent damage to loaf vol. and to grain and texture when large dosages of this reagent are used. Even when the effect is small for loaf vol. it remains marked for grain and texture. This buffering effect toward bromate has important com. significance because it provides a safeguard against the possibility of damaging flours that have already been brought close to their optimum "oxidation" condition by bleaching or by the addn. of other oxidizing agents. Examn. of 2 of the flours which had been thoroughly extd. with ether indicated that this buffering effect was not assocd. with the ether-sol. components of the flours. Treatment of 2 flours that responded quite differently to both bromate and milk, with cysteine-HCl, a protease activator, resulted in no increased differentiation of the flours. This was interpreted to mean that the protease content of the flours was not responsible for the differences noted. Dry-milk solids, together with the appropriate amts. of $KBrO_3$, produced increases in loaf vols. and improvements in texture beyond what could be obtained with optimum amts. of bromate alone. The extent of this response appeared to be inversely related to bromate response in most cases. Exceptions were noted in the durum and the unbleached hard red spring clear flours. In certain flours greater improvements were obtained with milk alone than with the optimum dosage of bromate. This was particularly applicable to the low-strength flours. In all cases, however, milk gave some improvement in both loaf vol. and texture over what could be obtained with bromate alone. L. H. Bailey

Determining maximum and minimum percentage of constituent substances by control analysis in milks used for food; establishing standard types and differentiating between adulteration and low quality. José Luis Andrade. *Bol. ministerio sanidad y asistencia social* (Venezuela) **4**, No. 5, 82–96(1939).—Of the 4200 cows supplying milk to Caracas 85% are a mixed (Holstein-Criolla) breed; the rest are Criolla and other native breeds. From numerous analyses the following standards of quality have been established (min. and max. limits are stated in succession): d_{15} 1.028, 1.0345; total solids 11.5, —; solids not fat 8.5, —; fat 3.00, —; total protein 2.75, 4.10; lactose 4.2, —; ash 0.7, 0.9; Cl 0.07, 0.15; acidity (cc. 0.1 *N* NaOH) 15, 19; acidity (percentage of lactic acid) 0.135, 0.17; serum density 1.026, —; f. p. 0.59, 0.53 (Beckmann cryoscope); refraction (cupric method) 36.0, 39.0; pH 6.5, 6.9. It is recognized that these properties may be somewhat subject to seasonal variations. It is believed that the stated limits will serve as a guide (not to be too rigidly interpreted) for judging whether or not a given sample of milk is adulterated. The analyses were made with raw milk. Julian F. Smith

Preventing development of oxidized flavor in milk through the addition of small amounts of pancreatic enzyme. E. O. Anderson. *Milk Dealer* **29**, No. 3, 32, 82(1939).—The pancreatic enzyme powder is mixed with a small amt. of water in the ratio of 1 g. for 10 to 40 gal. of milk. This is added to cold raw milk and the milk pasteurized in the usual way. This procedure prevents the development of oxidized flavor in milk whether the off-flavor is due to metal contamination or to naturally high susceptibility of the milk to the development of oxidized flavor. A. H. Johnson

Milk peroxidase. W. Grimmer and W. Kleinau. *Milchw. Forsch.* **20**, 131–8(1939).—Milk peroxidase can be extd. from milk or whey by silicates or by pure silicic acid hydrate. An elution with NH_4Cl soln. is possible only as long as adequate quantities of sol. protein are present in the adsorbate. After repeated adsorption, an elution without addn. of a soln. of protein or peptone is unsuccessful. On dialysis of the protein-contg. eluates, the peroxidase seps. with the pptg. globulin. From peptone-contg. eluates, it adsorbs on the collodion membrane with a definite quantity of peptone. From the protein ppts. the peroxidase can be sepd. as an insol. substance by pancreatic digestion. It then gives no protein reaction. Dialyzed solns. of the enzyme give the peroxidase reaction with guaiac tincture, guaiacol and benzidine, but not with *p*-phenylenediamine and Rothenfusser's reagent. This

last is colored green. A violet color is produced if the reaction mixt. contains added alkali, protein, peptone, amino acids or dialyzer liquid, histidine-HCl being particularly active. Peroxidase solns. contg. peptone are stable for a long time; adsorbates dried over H_2SO_4 lose their activity very quickly. E. O. Whittier

Lipase action in mixtures of raw and pasteurized homogenized milk. I. A. Gould and G. M. Trout. *Mich. Agr. Expt. Sta., Quart. Bull.* **22**, 101–5(1939); cf. *C. A.* **29**, 5526⁷.—When homogenized pasteurized milk is mixed with homogenized raw milk and the mixed milk stored, the increases in acidity obtained are greater than the calcd. values if only the raw product undergoes lipolysis. This indicated that the fat of the pasteurized milk is also split to some extent by the lipase action. The titration of pure fat obtained by churning a mixt. of homogenized raw and unhomogenized pasteurized milk stored for various periods shows that such fat has undergone appreciable lipolysis. The fat comes from both the homogenized and unhomogenized portions of the milk. C. R. Fellers

The vitamin C content of milk. R. G. Washburn and W. E. Krauss. *Ohio Agr. Expt. Sta., 56th Ann. Rept.* (in *Bull.* **592**), 85–6(1938).—Ordinary raw milk was held in cool storage for 6 and for 24 hrs. over a 56-day period. The samples were titrated each day for ascorbic acid content and some was fed to guinea pigs for a biol. estn. of vitamin C content. Although the titration values indicated losses of 12.9 and 29.4%, resp., after 6 and 24 hrs.' storage, the biol. values of all the milks were much alike. From 9.7 to 14.6% of the ascorbic acid in the stored samples was reversibly oxidized. This fact had not been considered in the previously reported comparison of chem. and biol. methods for the estn. of ascorbic acid in milk. In a second expt. covering this point, much better checks were obtained between the chem. (including reversibly oxidized ascorbic acid) method and the biol. assay for vitamin C. C. R. Fellers

Producing vitamin D milk. M. J. Dorcas. *Milk Dealer* **29**, No. 4, 64–8(1940).—The photochem. principles involved in the irradiation of milk to increase the vitamin D content are discussed. A. H. Johnson

Some factors affecting certain milk properties. III. Effect of roughages on ascorbic acid. O. F. Garrett, R B. Arnold and G. H. Hartman. *J. Dairy Sci.* **23**, 47–52 (1940); cf. *C. A.* **34**, 533⁷.—Whether beet pulp, corn silage or grass silage was fed had no significant effect on the amt. of ascorbic acid secreted into the milk. Factors assocd. with the individual cow had a marked influence on the stability of the ascorbic acid while the milk is in storage. If the milk is pasteurized in such a manner that it is protected from violent agitation, sunlight, and metal contaminations, the loss of ascorbic acid during storage is not significantly greater than that of the corresponding raw milk. The feeding of properly ensiled molasses grass silage had a greater stabilizing effect on ascorbic acid of milks in storage than did corn silage or beet pulp. The grass silage was also superior to the other 2 roughages in producing milk with yellow color and good flavor. A. H. Johnson

Effect of heat on milk with special reference to the cooked flavor. I. A. Gould and H. H. Sommer. *Mich. Agr. Expt. Sta., Tech. Bull.* **164**, 48 pp.(1939).—The cooked flavor of milk is caused by the formation of sulfides which occurs when milk is subjected to sufficiently high temps. or to other changes occurring simultaneously with this formation. The liberation of sulfides is responsible for the heat lowering of the oxidation-reduction potential of milk. The sulfides also serve to explain the heat retardation and prevention of the oxidized flavor. The sulfides of milk are contributed by the milk serum. However, the more intense liberation found in milk and cream was due to the presence of a substance closely assocd. with the fat phase. This substance is sepd. from the cream by churning and passes into the buttermilk. The cooked flavor was closely related to the heat prevention of oxidized flavor, when Cu was added before heating at the rate of 1.4 p. p. m. Temps. sufficiently high to cause a cooked flavor also largely inhibited the development of the oxidized flavor. When the addn. of Cu followed the heating process, there was no relation between the cooked and oxidized flavors. 86 references. C. R. Fellers

Compounds of phosphorus in milk. B. N. Acharya and S. C. Devadatta. *Proc. Indian Acad. Sci.* **10B**, 221–8 (1939).—A review and discussion. The existence of 5 independent types of P was established, namely: ortho, pyro, org. P compds. insol. in $Ba(OH)_2$ at pH 9 and hydrolyzable and nonhydrolyzable org. P compds. sol. at pH 9. The acid-sol. P consists of casein P and lipoid P. The amts. of P present in these 7 varieties were estd. directly and results tabulated. J. C. Jurrjens

Phosphorus, calcium and magnesium in milk. B. N. Acharya and S. C. Devadatta. *Proc. Indian Acad. Sci.* **10B**, 229–35(1939).—The portion of milk insol. in trichloroacetic acid is mostly casein which had adsorbed some ions of Ca and Mg, while the acid-sol. but H_2O-insol. portion consists of tri-Ca and Mg phosphates and org. P. Scum, which collects after heating the milk, is derived both from the acid-sol. and insol. portions. On dialysis the acid-insol. portion becomes partly H_2O-sol. The H_2O-sol. portion of milk consists of acid phosphates of Ca and Mg. Results of analysis of 100 cc. of milk are tabulated. J. C. Jurrjens

Curd tension of chocolate milk drinks. G. Hadary and H. H. Sommer. *Milk Dealer* **29**, No. 3, 42(1939).—The curd tensions of 7 different chocolate milks were 3, 2, 2, 1, 14, 2, and 4, resp. These low curd tensions were due in part to the higher pasteurizing temp. to which chocolate milks are subjected but chiefly to the cocoa itself. The effects of sugar and such suspending agents as starch and locust bean gum were negligible. A. H. Johnson

Experiments on the suitability of corn silage in the production of milk for buttermaking. E. Crasemann and F. Christen. *Landw. Jahrb. Schweiz* **54**, 27–54(1940).—If corn silage is fed to cows before or during milking, abnormal taste and odor appear in butter derived from the milk. Chem. and bacteriol. investigations have given no evidence as to the substance responsible for these abnormalities. E. O. Whittier

Resazurin test for detecting mastitis. R. R. Russell, T. Palmer-Jones and G. M. Moir. *New Zealand J. Sci. Tech.* **21A**, 161–7(1939).—Results obtained from analysis of 814 individual quarter samples show good agreement between the resazurin test and cultural microscopic methods of diagnosing mastitis. The test is sensitive to the presence of streptococci, staphylococci or leucocytes, but is comparatively insensitive to micrococci in milk drawn aseptically from the udder. The test is simple, rapid and economical. C. R. Fellers

Chemical and bacteriological analyses of some samples of soda water, ice cream and sherbet from Lima. Alfonso del Castillo. *Bol. soc. quím. Peru* **5**, 134–45(1939). —Soda water, ice cream and sherbet were chemically analyzed for total solids, reducing sugars and acidity. Total bacteria as well as *Bacillus coli* were detd. Chem. analyses showed considerable variation among the different samples. Sterilized drinks were free from *Bacillus coli* but they were present in unsterilized drinks, being introduced by the water used. Similar conditions held for pasteurized and unpasteurized ice cream. It is recommended also that manufg. equipment be sterilized. Large quantities of *Bacillus coli* were found in sherbets owing to carelessness in manuf. and handling. L. Rosenstein

The quality of the Indian and the Western table butters. Zal R. Kothavalla and Noshir S. Doctor. *Indian J. Vet. Sci.* **6**, 151–64(1939).—Butter samples were prepd. from selected Jersey (English), Sindhi and Surti buffalo (Indian) herds. English butter scored slightly higher in flavor on opening the tins, but this lasted only a short time. Indian butter scored higher as to body, firmness and standing up quality. The differences might be attributed to component fatty acids as well as carotene content, and these in turn to differences in breed. 21 references. J. C. Jurrjens

Influence of neutralizers on the acidity of butter and butterfat. I. A. Gould and R. C. Townley. *Mich. Agr. Expt. Sta., Quart. Bull.* **22**, 96–101(1939).—Pro-

gressive lowering of the acidity of cream by the use of different neutralizers results in a corresponding lowering of the acidity of the butter and butterfat obtained from this cream. All neutralizers were not equally efficient in lowering the acidity, the limes being less efficient than the soda neutralizers. The acidity of the butterfat was lower than the acidity of the butter. It is necessary to consider the type of neutralizer and the degree of neutralization in connection with acid values of the butter and butterfat. C. R. Fellers 1

Estimation of butter losses in churning. W. J. Wiley. *J. Council Sci. Ind. Research* **12**, 391–6(1939).—The methods proposed by Udy (*C. A.* **24**, 1678) and by Bird and Derby (*C. A.* **32**, 5520[2]) are reasonably accurate, judged by direct detn. of butter fat in the buttermilk and wash water. Philip D. Adams 2

Bacteriology of butter. VII. Effect of reworking butter on growth of bacteria. H. F. Long and B. W. Hammer. *Iowa Agr. Expt. Sta., Research Bull.* No. **263**, 185–200 (1939); cf. *C. A.* **33**, 6974[7].—The reworking of butter often accelerated various microbiol. changes. When butter culture was added to the cream, the pH values of the butter serum decreased more rapidly after reworking. When lipolytic organisms were added to the cream, the acidities of the fat increased more rapidly. The time required for development of defects was usually decreased. 3

VIII. Relationship of Achromobacter putrefaciens to the putrid defect of butter. *Ibid.* No. **267**, 341–72.—Of 58 com. samples of butter having the typical putrid defect, 41 or 70% yielded *Ach. putrefaciens* and 6 yielded an apparent variant form of this organism. The origin of this organism is sometimes the dairy water supply. The bacteria developed in unsalted butter at pH values 5.8–6.8 but not when the pH of the cream was 4.5. Salt contents in the butter from 1.08 2.41% did not inhibit growth of the organism. In storage, the nos. of bacteria greatly declined. C. R. Fellers 4

Slow acid production by butter cultures. F. E. Nelson, L. A. Harriman and B. W. Hammer. *Iowa Agr. Expt. Sta., Research Bull.* **256**, 219–87(1939).—The inhibitory principle active against *Streptococcus lactis* in slow acid production possesses the general characteristics of a bacteriophage. No method was found to eliminate it from butter cultures. C. R. Fellers 5

Blending and processing. Practical suggestions in the making of process cheese. C. R. Barker. *Natl. Butter Cheese J.* **30**, No. 12, 14, 39(1939); cf. *C. A.* **34**, 535[7].—Characteristics of cheese such as acidity, age, texture and flavor are discussed in relation to the manuf. of process cheese. A. H. Johnson 6

The use of colloid mill in the production of margarine. N. Kozin and S. Bessonov. *Maslobo˘ino Zhirovoe Delo* **15**, No. 5, 23–5(1939).—Promising lab. results are reported. Chas. Blanc 7

Storage of margarine in the atmosphere of combustion gases. M. Ravich and E. Shmidt. *Maslobo˘ino Zhirovoe Delo* **15**, No. 4, 20–3(1939).—Comparative tests on the effect of storage of margarine in air and in a current of combustion gases (CO_2 85.8, N 14.1 and O 0.1%) at room temp. are described. After storage for 100 days in the atm. of combustion gases, the margarine samples showed no changes in their phys. appearance. The samples held in the air atm. became moldy after 13 days of storage and were thoroughly infected with green and brown molds after 28 days. The acidity of margarine showed no change after 45 days of storage in a current of combustion gases, while that of samples held in air increased six-fold. Chas. Blanc 8

Changes taking place in fats during cooking. V. R. Chertok and Ts. L. Baskovich. *Voprosy Pitaniya* **7**, No. 4–5, 217–21(1938); *Khim. Referat. Zhur.* **2**, No. 4, 139(1939).—In frying with butter at 150–200° hydrolysis and oxidation produce some low-mol. acids; sapon. no. increases from 224–44 to 247–50, free acids, peroxides and hydroxy acids increase, and I no. decreases from 40 to 29. Very little change in fats was observed in boiling. The acidity remained unchanged; evidently the acids formed from hydrolysis were lixiviated. Only formation of low-mol. acids was observed (the sapon. no. increased from 225 to 234). W. R. Henn 9

Physical and chemical characteristics of lards and other fats in relation to their culinary value. II. Use in plain cake. Belle Lowe and P. Mabel Nelson. *Iowa Agr. Expt. Sta., Research Bull.* **255**, 146–216(1939); cf. *C. A.* **32**, 2236[5,7]; **33**, 5929[2].—The cakes studied contained about 40 parts of fat to 100 parts of flour. Data are given for 42 samples of lard. For each fat there is an optimum temp. at which it creams best, this temp. being lower for softer fats of higher I_2 no. and higher for firmer fats. Smooth lard creamed to a larger vol. than grainy lard at both 25 and 30° when both textures of lard were obtained from the same original lard. The effect of phys. factors of the fat on cooking and cake quality are discussed. Fat distribution in cake was affected as follows: As the temp. of the ingredients at time of mixing was elevated the proportion of fat distributed within the crumb, i. e. as an oil-in-water emulsion and as pools, increased, but the quality of the cakes decreased. Cake vols. became smaller with larger creamed-fat vols. Bibliography. C. R. Fellers

Adulteration of lard. E. Renaux. *J. pharm. Belg.* **21**, 549–50(1939).—Three samples which appeared to be hydrogenated fish oils gave tests which corresponded fairly well with those given by lard except their microscopic appearance under polarized light (brilliant needles observed only in the true lard) and their response to the Tortelli and Jaffe color reaction (cf. *C. A.* **8**, 3723; **9**, 1255) (true lard gives no color; samples gave yellow to blue colors). S. W. Goldstein

Meat from the point of view of inspection. Rubem Pecego. *Rev. alimentar* **3**, 165–71(1939).—The compn. of different com. meats and phys. and chem. methods of inspection for disease and spoilage are discussed. L. E. Gilson

Meat products. W. J. Mathis, C. E. Shepard and E. M. Bailey. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **426**, 14–18(1939); *43rd Rept. Food Products.*—Soybean flour or meal is not prohibited in meat products in Conn. Its presence can be detected by means of the urease test and confirmed microscopically by the detection of cells characteristic of soybean. A neg. urease test does not necessarily mean that soybean flour is absent; the microscopic examn. should be made in all cases. Quant. methods of estn. are lacking. In approximating skim-milk powder from the lactose found, the factor 1.8 has been used to allow for such powders as may contain somewhat more than 50% lactose. An allowance of 0.5% is made for starch that may be due to seasoning rather than to starchy fillers. Analysis of 30 samples of frankfurts for lactose by the yeast method (*C. A.* **32**, 7150[1]) showed that filler was present and not declared, in 8 samples. C. R. F.

Ripening of sausage in casings. M. Guastalla. *Ind. ital. conserve* **14**, 115–17(1939).—Analyses of Felino type sausage, in paste form and in pig intestine casings, show progressive desiccation with moisture content falling from 55% to 24% (4 months) and finally 20% (8 months). Aside from the corresponding percentage decrease in N, fat, ash and NaCl there are certain chem. changes in the sausage. Sol. matter (total or on the ash-free basis) first increases, then decreases; sol. N follows a like course. Acidity first increases, then drops off slightly, but the medium remains distinctly acid. Ammonia N increases slightly in the first stage, then remains approx. const. Nitrate content is high at first but progressively decreases while nitrite, initially present only in traces, rapidly increases but later falls off again, sometimes disappearing entirely in the oldest samples. The rise in sol. matter and sol. N confirms the opinion that ripening is accompanied by slight peptonization. The decrease which then follows indicates a slow progressive insolubilization, probably because of phenomena involved in desiccation. The const. level reached by ammonia N shows that protein degradation tends to stop after a time. Julian F. Smith

Effect of benzoated brine dips on keeping quality of fish fillets. C. R. Fellers and E. W. Harvey. *Food Research* **5**, 1–12(1940).—NaOBz and MgOBz, and mixts. of these salts with BzOH, gave best results in extending the

storage and shipping life of strictly fresh haddock, cod and red perch fillets. CaOBz and NH_4OBz were least effective. The benzoate salts were used in a 5% NaCl brine in concns. of 0.15–0.40%, with an av. of 0.30% benzoate. Acidification to a pH value of 4–5 increased the effectiveness of the treatments. The benzoated brine dip for 2–3 min. has a cleansing and firming effect on the fillets. The action of the dipping solns. seems to be limited largely to the surface layers of fish except where the tissues are sepd. or broken. The period of acceptability of the fish was extended for several days at low temps. over untreated controls. Frozen fillets, which have been previously treated with benzoated brine, also keep longer after defrosting. The retention of benzoates in brine-dipped fillets is very small, averaging about 0.01% for a 2-min. dip in a brine contg. 0.3% NaOBz. The treatment imparts no off-flavor to the fish. Ice contg. 0.2–0.5% NaOBz was successfully prepd. Such ice possesses definite antiseptic action on fish packed in it, but the application to fish fillets is believed to be limited. C. R. Fellers

Influence of various types of rind injury on the incidence of water spot of navel oranges. L. J. Klotz and A. J. Basinger. *Bull. Dept. Agr., Calif.* **27**, 232–41(1938).—Water spot is a nonparasitic breakdown of the rind of citrus fruits, the most important factor of its origin being the inhibition of external water by the albedo or white portion of the rind. Invasion of the water-affected areas by decay-producing fungi causes rapid decline in the fruit. There may be a possibility of preventing water spot losses by means of a protective spray of paraffin wax. C. R. Fellers

Distribution of soluble solids in citrus juices. E. T. Bartholomew and W. B. Sinclair. *Calif. Citrograph* **24**, 352, 362–3 and 382–4(1939).—Excessive accumulation of sol. solids in the stylar ends of citrus fruits (valencias, navels and Thompson seedless grapefruits) does not occur until they are approaching maturity. A given segment as a whole may contain from 0 to 3.5% less total sol. solids than another segment in the same fruit. In the fruit on the outside of the tree, the 3 north (north side as it hung on the tree) segments have a higher sol.-solids content, in general, than the 3 south segments. The occurrence of a single frozen segment in a fruit appears to be positively correlated with the fact that this particular segment contains a considerable lower concn. of sol. solids than other segments in the same fruit. The color of the juice in one half of a segment is lighter or darker than that in the other half and the juice in a fruit having a south exposure is lighter than that of a shaded fruit. The total sol. solids and solid-acid ratio of navels are highest in the south-side fruit while with 1 exception the greatest percentage of titratable acid is in the north fruit. In the case of valencias the highest sol.-solid contents are in the south fruit and with 1 exception the acid is highest in the fruit from the south. A comparison of naval oranges on the basis of size (large, medium and small) shows that the total sol. solids, pH, reducing and total sugars increase from the large size oranges through the medium to the small sizes. The citric acid content is lowest in the large size oranges and is max. in the medium ones. The solids-acid ratio is highest in the small oranges and the same in the other 2 sizes. In the case of valencias the highest values for percentage of total sol. solids and citric acid and the reducing and total sugars are found in the small sizes and the lowest values in the large oranges. Both the pH and solids-acid ratio decrease from the large to the small size. J. R. Adams

Orange beverages. E. M. Bailey. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **426**, 9–10(1939); *43rd Rept. Food Products;* cf. *C. A.* **33**, 7664.—Three orangeades sold in Conn. contained 12–20% orange juice. Tests conducted to det. the stability of the ascorbic acid in fresh orange juice and in dild. orange juice showed that there is very little loss after storage for a day at room temp. C. R. Fellers

Chemical composition of important Hungarian plums. Jenő Becker. *Z. Untersuch. Lebensm.* **78**, 403–7(1939).—Analysis of 95 plum samples yielded total solids 13.31–24.02, sugar 8.8–13.96 (dry basis 56.6–77.1) acids 0.44–1.59% (dry basis 2.4–10.3%). M. M. Piskur

Blackberries do not contain tartaric acid. John R. Eoff, Jr., and W. J. McVeigh. *Fruit Products J.* **19**, 104, 111(1939).—Eleven samples of blackberry juice, representing canned, fresh, wild and cultivated fruit grown in various localities, were analyzed for the tartrate radical. No tartaric acid, nor tartrates, were found in any of the samples. The Kling method, capable of detecting 2–3 mg. % of tartrates, was used. P. L. H.

The sulfuric acid oil digestion method for avocados. Hamilton P. Traub, Cloyde H. Russell, Charles T. O'Rork, Jr., J. M. Tubbs and R. E. Caldwell. *Proc. Am. Soc. Hort. Sci.* **36**, 429–31(1939).—The ground sample is digested by H_2SO_4 for 30 min. at 55° and the amt. of oil detd. in a Babcock bottle. The error is less than 2.5%. Lawrence P. Miller

Spray-residue control on California fruits. Alvin J. Cox. *Bull. Dept. Agr., Calif.* **27**, 633–44(1938).—In general, 1% HCl was effective in removing Pb and As spray residues from fruit. Wash solns. can be increased in effectiveness by adding 10–15 lb. NaCl per 100 gal. of water and raising the temp. to 105°F. This temp. is more effective than an increase in HCl concn. for Pb removal. C. R. Fellers

Effect of some varietal, cultural, harvesting, and storage conditions upon the content of certain mineral salts and vitamins in tomato fruits. I. C. Hoffman, W. E. Krauss and R. G. Washburn. *Ohio Agr. Expt. Sta., 56th Ann. Rept.* (in *Bull.* **592**), 66–7, 92(1938); cf. *C. A.* **32**, 5559⁶. —Rather wide differences were found in the ascorbic acid content of varieties. There was no correlation between ascorbic acid content and color of flesh. Stage of maturity and acidity were both closely correlated with ascorbic acid. Ascorbic acid content increases progressively in the fruits to maturity. Moist soil conditions are also conducive to higher ascorbic acid content. Similarly high fertility favored high ascorbic acid in tomato fruits. Different pH levels in the soil tended to reduce ascorbic acid slightly from alk. to acid conditions when nitrates were supplied, but where ammoniates were used, the slight changes did not appear significant. Seventy-five varieties of tomatoes were examd. The acidity, calcd. as citric, of the dry pulp ranged from 3.88 to 4.44, and the ascorbic acid content, from 0.114 to 0.464 mg. per cc. Total pigment concn. (lycopene + carotene) on 56 varieties was 0.0018–0.0970 mg. per g. Only 4 varieties, white or yellow, contained carotene by this method. The small amt. of carotene in the pigment is masked by the lycopene. The spectrophotometer cannot detect up to 4% carotene in mixts. contg. large amts. of lycopene. C. R. Fellers

Quality and yield in tomato products. D. J. Tilgner and R. Schillak. *Polish Agr. Forest Ann.* **39**, 361–93(in English, 393–4)(1937).—The manuf. of tomato products in Poland is criticized. The fundamental errors in processing procedures are: inadequate sorting and washing, loss of juice contg. nutritive salts, sugars and other dissolved solids and lack of standardization procedures and constants for the various products. The authors suggest the following specifications for the tomato products: for purée, extract and paste not less than 12%, 20% and 35% total solids, resp.; no less than 35% reducing sugars, acidity (as citric acid) not greater than 12%, salt content 5% (based on total solids), Cu not to exceed 0.003% and no added artificial coloring or chem. preservative. Mold and bacteriol. examn.: not to exceed 66% mold filaments per examd. field, 100 million bacteria per cc. and 125 spores per 1/60 cc. according to the Howard method). Adequate labeling is to be provided. C. T. Ichniowski

Vitamin A content of some commercially canned tomato juice. Charles F. Poe, Ola K. Gant and Eloise Griffin. *Fruit Products J.* **19**, 73–4, 88(1939).—Expts. performed on male albino rats showed that whole tomato juice is a good source of vitamin A. The min. amount of the vitamin found in this juice was 5.00 units per cc.; the max. vitamin A content was 8.74 units per cc. There was no marked difference in the vitamin A content of any of the 15 brands of tomato juice tested. The general average of

vitamin A in whole tomato juice was 7.12 units per cc. Filtered tomato juice proved to be a poorer source of vitamin A than the whole juice; a min. of 0.10 units per cc. and a max. of 0.14 units per cc. were found. According to the results recorded in the article, the whole tomato juice contains 59 times as much vitamin A as the filtered juice. 13 references. Edward A. Ackermann

The vitamin C content of some fruits of the Dutch East Indies. IV. J. P. Spruyt. *Geneeskund. Tijdschr. Nederland.-Indië* **79**, 2912–17(1939); cf. *C. A.* **30**, 4223[8]; **32**, 5453[4]; **33**, 6464[3].—Results are given of the examn. of 48 Indian fruits as to their vitamin C content. The same methods were used as for those previously examd. The high vitamin C content of malaka fruit (*Phyllanthus Emblica, L*) namely 30–40 mg. of ascorbic acid per g. of powder, suggests a cheap vitamin C source for native use. A noticeable reduction in acid medium was found, as in about 3 weeks time all vitamin C was destroyed, this fact being of importance for the medical practitioner in prescribing vitamin C-contg. medicine. J. C. Jurrjens

The vitamin C (ascorbic acid) content of ten varieties of watermelons. R. E. Clegg and G. Howard Satterfield. *J. Am. Dietet. Assoc.* **16**, 39–42(1940).—In the heart of 10 varieties of watermelon the vitamin C content varied from 5.04 to 13.70 mg. %. The red tissue immediately under the rind contained 4.22 to 7.37 mg. %. There is no relation between the size and shape of the watermelon and its vitamin C content. The Stone Mountain variety was highest and the Cuban Queen lowest in vitamin C content. Preserved and pickled rind contained little vitamin C. E. Curzon

Determination of carotene in fresh and frozen vegetables. I. Carotene content of green snap beans and sweet corn. Wm. I. Zimmerman, Donald K. Tressler and Leonard A. Maynard. *Food Research* **5**, 93–101(1940).—The method of Russell, Taylor and Chichester for the detn. of carotene (*C. A.* **29**, 5473[6]), slightly modified, gave good results for carotene estn. in vegetables. Biol. assay showed that much of the pigment in Golden Cross Bantam sweet corn is not carotene. The sweet corn contained 0.6–1.2 γ carotene per g. by bioassay; snap beans 2.4–4.1 γ. No appreciable losses of carotene occurred during the storage of vegetables at either −17.8 or at −40.0°. C. R. F.

Vitamin content of green string beans when cooked or canned and stored. Helen L. Mayfield and Jessie E. Richardson. *Montana Agr. Expt. Sta., Bull.* **373**, 3–13 (1939).—Canned green string beans, taken from storage and reheated, are nearly as rich in vitamin A as the freshly cooked beans; but lost about 40% of their vitamin B_1 content. The loss in vitamin C was 80–85% of that originally present in the raw beans. During cooking, losses of 30–40% in vitamin C were found. Typical values expressed in mg. per g. of ascorbic acid are: raw Burpee Stringless beans, 0.27; fresh cooked, 0.18; home or commercially canned 0.03–0.06. C. R. Fellers

Chromatographic identification and biological evaluation of carotene from mature soybeans. Wm. C. Sherman. *Food Research* **5**, 13–22(1940); cf. *C. A.* **33**, 8849[1].—The biologically active carotenoid pigments extd. from 5 varieties of mature soybeans consist of 80–88.8% β-carotene and 2.5–11.8% α-carotene. *Cryptoxanthin* was not found in any of the soybean seeds examd. Similar exts. of yellow corn contained 66% cryptoxanthin. The results from the chem. analyses were substantiated by biol. assays. C. R. Fellers

Vitamin F (linoleic acid) in sesame oil. A. A. Hoover. *Ceylon J. Sci.* **D5**, 55–7(1939).—A sample of com. oil contained 14.2% linoleic acid, entirely the α modification, and very little linolenic acid. In 4 samples of com. oil the I values were 90–105 and sapon. values 185–187. K. D. Jacob

Changes in vitamin C during the boiling of turnip greens. W. W. Floyd and G. S. Fraps. *Food Research* **5**, 33–41 (1940).—Turnip greens contain 67–422 mg. of ascorbic acid per 100 g. Losses of total vitamin C content by ordinary cooking methods ranged from 16 to 37%. Slow cooking caused somewhat greater losses than rapid cooking. The losses were the same whether or not the pans were covered during the cooking process. C. R. Fellers

Fat acidity in relation to heating of corn in storage. Lawrence Zeleny. *Cereal Chem.* **17**, 29–37(1940).—The rate at which heat is developed depends upon the moisture content of the grain, the temp., the available O_2 supply and upon certain characteristics of the grain itself, which are not completely understood. The acidity of grain, particularly of corn, is a more reliable measure of its degree of soundness than other available chem. or phys. tests. Fat acidity is expressed in terms of mg. of KOH required to neutralize the free fatty acids extd. from 100 g. of corn, calcd. to a dry matter basis. The rate of spontaneous heating of grain can be predicted much more accurately when moisture and fat acidity are considered together than with moisture alone. It was shown that corn with a moisture content of 17% and a fat acidity of 100 can be expected to heat in storage as rapidly as corn with a moisture content of 21% and a fat acidity value of 20. L. H. Bailey

Comparative study of the chemical composition of five varieties of soybeans. R. C. Burrell and Alvin C Wolfe. *Food Research* **5**, 109–13(1940).—Chem. analyses, including carbohydrate fractions, are given for Illini and Peking varieties as well as for the 3 edible varieties, Bansei, Jogun and Kura. No clear cut chem. differences were found which would serve to differentiate edible and field varieties of soybeans. In general, crude fiber content was lower in the edible varieties. Considerable quantities of galactans are present. C. R. Fellers

Behavior of microörganisms at subfreezing temperatures. I. Freezing redistribution studies. Vernon H. McFarlane. *Food Research* **5**, 43–57(1940).—The effects of solutes on distribution patterns in ice were studied. The yeast-cell distribution pattern differed for sugar, NaCl and HCl. The presence of H ions in a medium hastened the destruction of yeast cells and sometimes markedly altered the distribution patterns of these cells in the frozen mass. **II. Distribution and survival of microörganisms in frozen cider, frozen sirup-packed raspberries, and frozen brine-packed peas.** *Ibid.* 59–68.—In 750-cc. containers of cider frozen and stored at −20°, microbial forms, sol. solids and total titratable acids were concd. in central cone-shaped areas and in surface areas. There was no marked redistribution of microbial forms, sol. solids or H-ions in frozen sirup-packed raspberries or brine-packed peas. The microörganisms decreased most rapidly in those portions of the frozen mass contg. the highest sol. solids content. Large nos. of bacteria remained viable in frozen peas after storage for 24 weeks at −20°. C. R. F.

The alkaloid content of lupines. Victor Lukazewicz. *Polish Agr. Forest Ann.* **39**, 485–6(in French, 487)(1937).—The ordinary or "bitter" lupines with alkaloid contents ranging from 0.7 to 1.3% are unsuitable as cattle fodder. A "special" variety of *L. angustifolius* with an alkaloid content of 0.08% can be used for feeding without any treatment to decrease the content of the toxic principles. C. T. Ichniowski

Wax emulsions for vegetables. Hans Platenius. *N. Y.* (Cornell) *Agr. Expt. Sta., Bull.* **723**, 43 pp.(1939).—A wax coating inhibits the diffusion of water vapor and other gases. The rate of diffusion depends primarily on the soly. of the gases in the wax membrane. The thickness of the dried wax films are 1–2 μ. The coating caused a decrease in O_2 consumption but had no effect on CO_2 production by carrots. Waxing reduced sugar losses in carrots. The compn. of the com. wax prepns. Brogdex, Dowax and Brytene are given. Parsnips did not respond well to waxing. Leafy vegetables and also bunched vegetables always gave unfavorable results when waxed. C. R. Fellers

Some changes in marmalades: syneresis, molding, crystallization. Giuseppe Alesi. *Ind. ital. conserve* **14**, 138–41(1939).—Syneresis in fruit marmalades not only makes the product unsightly but also favors fermentation. A suitable citrate or tartrate concn. inhibits syneresis, but is likely to impair jelling properties. Citric acid may be used if the amt. is correctly calcd., with due allowance for differences between fresh and SO_2-preserved pulp and

for natural differences in pH. To avoid mold it is advisable not only to practice thorough sanitation but also to use a high sugar content (at least 60%) and to cook the product a little thicker than the customary consistency. With sufficiently high sugar content and low surface moisture content mold will not grow. These conditions are related to the osmotic pressure in the substrate. Crystn. is favored by high sugar content (about 70%), excessive or deficient ratio of invert sugar to sucrose, pectin deficiency and prolonged cold storage. Sugar inversion is an important process in making marmalades and close attention to acidity, temp. and other conditions is required. With pulp from low-acid fruits, for example, when fresh or preserved by sterilization (not with sulfite) all the sugar is added before cooking, but the pectin and the correct amt. of citric acid are withheld till near the end of the cooking. Julian F. Smith

Lead in maple-tree products. Elphège Bois, Maurice Lessard and Armand Roberge. *Trans. Roy. Soc. Can.* III, **33**, 107–12(1939).—A small amt. of Pb was found to be dissolved from tin plate and solder by maple sap during the process of sugaring. Painting and lacquering the app. was not sufficient protection against the corrosive action of the hot sap and a slight taste was imparted to the maple sugar. Boilers and evaporators of Al are recommended. J. W. Shipley

Determination of the water-soluble tannins in cocoa according to the cinchonine method. K. Kappeller. *Z. Untersuch. Lebensm.* **78**, 393–401(1939).—The effect of the amt. of sample, concn. of tannins (amt. of diln.), pH, and presence of milk and nuts on the detn. of the water-sol. tannins by pptn. with cinchonine was investigated. A modification of the method replaces filtering with centrifuging and decanting the supernatant liquid. It is reported that the results obtained are high because cocoa exts. contain nontannin materials which are also pptd. with cinchonine. The results are therefore not considered to be the true amt. of water-sol. tannins present. The method cannot be applied to chocolate contg. milk or nuts. M. M. Piskur

Determining paprika color components by means of the step-photometer. L. v. Cholnoky. *Z. Untersuch. Lebensm.* **78**, 401–3(1939).—Data are presented for applying the step photometer to the method previously described (*C. A.* **34**, 1090⁹). M. M. Piskur

Processing the macadamia (nut). R. H. Moltzau and J. C. Ripperton. *Hawaii Agr. Expt. Sta., Bull.* **83**, 31 pp.(1939); cf. *C. A.* **32**, 8177⁴.—The nut contains about 25% moisture when it falls to the ground. Least damage to the kernel results when cracking takes place at a moisture content of 3.5%. Air-, sun- or artificial drying methods are used. Mech. equipment for cracking the nuts is described. The kernels are reduced to a moisture content of 1.5% by very slow oven roasting, starting at 110°F. and ending at 170°F., the whole operation requiring about 8 hrs. The kernels are cooked either by (1) immersion in a vat of hot oil at 275°F. for 12–15 min. or (2) roasting at 275°F. for 40–50 min. Refined coconut oil is used for the oil bath during the oil cooking method. After cooking, the nuts are spread in thin layers to cool and are sprayed with an adhesive such as a 15% soln. of gum arabic followed by salting. Vacuum-packed salted nuts in sealed containers keep without deterioration for several years. The fresh kernels may be kept safely in cold storage under 40°F. for 12 months. At ordinary temps., deterioration in quality of the nuts takes place rapidly. C. R. Fellers

Compilation of information on kudzu, Pueraria thunbergiana. I. E. Miles and E. E. Cross. *Miss. Agr. Expt. Sta., Bull.* **326**, 3–14(1939).—This legume contains approx. 2.83% N and 0.27% P. The total digestible nutrients in the dry matter are 50.8%. The plant is a *prolific N fixer in the soil.* C. R. Fellers

Commercial feeding stuffs. E. M. Bailey. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **425**, 99 pp.(1939); *Rept. on Inspection*, 1938.—Of the 888 samples of animal feeds examd., 130 were deficient in 1 or more items. Of the 55 samples of vitamin D carriers for animal feeding, 18 samples fell below the guaranteed potencies of vitamin D. C. R. Fellers

Indigestible carbohydrates in feeds. V. G. Heller and Robert Wall. *J. Nutrition* **19**, 141–9(1940).—A modified method (cf. Williams and Olmsted, *C. A.* **29**, 3700⁷) of detg. lignin, hemicellulose and cellulose contents of feeds is given. Both the total content of and the ratio between the quantities of lignin, hemicellulose and cellulose of various cereal grains and grasses vary considerably. The indigestible residue detd. by the method is much greater than the analogous crude fiber value. The apparent utilization of cellulose in feeds is greater than that of lignin. The cellulose of certain mixts. of feeds is better utilized than that of others; the utilization is detd. to some extent by other ingredients of the mixt. C. R. Fellers

Fodders of note. M. Kling and A. Imhoff. *Prakt. Blätter Pflanzenbau Pflanzenschutz* **17**, 140–58(1939).—Results of chem. analyses to det. feeding values of weeds and many miscellaneous feeds are reported. Data cover the period from Jan. 1, 1938 to June 1, 1939. Edwin J. Sciferle

The food value of hay as affected by the process of curing. B. J. Senior and E. J. Sheehy. *J. Eire Dept. Agr.* **36**, 5–37(1939).—The results are given of an investigation extending over a period of yr. into the quant. and qual. changes taking place in grass herbage during the process of hay making and into the effect of exposure to weather influences on the nutritive value of hay. The rapid drying of green herbage in a current of air at 140°F. did not alter the digestibility to any appreciable extent. Exposure to weather influences, especially that of rain, altered the color, leached out the more sol. constituents, decreased the digestibility and, with respect to minerals, vitamins and energy content reduced the nutritive value. Under conditions of practical hay making on the farm the unavoidable loss of dry matter between the time of cutting the grass and the time of feeding the hay, 5–7 months later, ranged from about 22% in a season of favorable weather to 25% under adverse weather conditions. When the grass was allowed to lie out for 3–4 weeks before being put into cocks the corresponding figure for loss of dry matter was 36–42%. The difference in digestibility between fresh grass and hay made therefrom under favorable conditions was 2–3%. In unfavorable weather, even when the hay was saved as rapidly as possible, the loss in digestibility was as high as 8–10%. With prolonged exposure to weather the digestibility coeffs. of the dry matter were decreased nearly 30%. The total loss, comprising the quant. reduction and the qual. deterioration, which a unit wt. or the produce of a unit area of green herbage suffered between the time of cutting and the time of feeding the hay, expressed as total digestible nutrients, was in favorable hay-making weather not greater than 25%; in damp weather when the drying was protracted the total loss was about 28% and in very unfavorable wet weather it was as high as 33%. When the hay is exposed to weathering influences for an unduly long period during the hay-making process the loss, without taking into account heating in the stack or wastage in the haggard, may be as high as 58%. Not only was the mineral content of severely weathered hay reduced but there was an appreciable reduction in the assimilability of the remaining Ca and P as a result of weathering. Exposure rapidly reduced the carotene content of green herbage. Hay made up with all possible expedition in very adverse weather had about one-seventh the carotene potency of the original green herbage and similar hay, unduly weathered, contained only a trace of carotene. Feeding expts. demonstrated not only the superiority of good-quality hay overweathered material in respect to energy value, but also pointed to nutritive deficiencies in the weathered hay, which affected adversely the appearance of the skin and the general health of the animal. K. D. Jacob

Digestibility and nutrition value of artificially dried grass. E. Brouwer and N. D. Dijkstra. *Verslag. Landb. Onderzoek.* No. **45**, C, (5), 119–40, 143–7(in German, 140–2)(1939).—It was found that the av. digestible crude protein was 11.7%, digestible albumin 9.5% and the

starch value 57.8%. The difference in these respects with fresh grass is very small. Based on the quality of the dry matter, the feed value of the dried grass is higher than that of the best quality hay, but lower than other feed. J. C. Jurrjens

Pasture studies. XVI. Nutritive values of Kentucky blue grass, red top and brome grass with particular reference to the relation between the chemical composition of the herbages and the live weight gains made by the animals subsisting thereon. E. W. Crampton and Robert Forshaw. *J. Nutrition* 19,°161–72(1940); cf. *C. A.* 33, 8850².—Feeding value of pasture grasses varies considerably during the growing season; e. g., it is of greatest value for growth in the spring and fall. In midsummer, the availability of the carbohydrate fractions of herbages is materially reduced. Protein content of grasses is highly correlated with wt. gains in animals, yet there is no evidence that protein as such is a limiting factor in the growth-promoting value of immature pasture herbage, but rather that increases in protein probably represent merely increases in available energy. Et_2O-ext., fat and crude fiber have little effect on wt. gains. C. R. Fellers

Preparation of silage without butyric acid fermentation. J. van Beynum and J. W. Pette. *Verslag. Landb. Onderzoek.* No. 45, C, [6], 149–69(in English, 169–71)(1939). —From expts. conducted the conclusion is drawn that it is possible to obtain a butyric acid-free silage when the latter is prepd. in a water-tight silo and when, during the filling of the silo, a sufficient quantity of sugar or inorg. acid is added dissolved in so much water that the silage is covered by the juice. J. C. Jurrjens

Value of corn gluten meal for feeding poultry. R. C. Ringrose, L. C. Norris and G. F. Heuser. *N. Y.* (Cornell) *Agr. Expt. Sta., Bull.* 725, 18 pp.(1939).—Though lacking in vitamin G (riboflavin), corn gluten meal gave good results in poultry feeding and in egg production. The corn gluten furnished about 20% of the total protein in the ration which also included dry skimmilk and meat-scrap. C. R. Fellers

Soybean-oil meal a good protein feed for chicks. H. J. Sloan and L. E. Card. *Ill. Agr. Expt. Sta., 49th Ann. Rept.* 1937, 120–1.—When used as a protein supplement with dried skimmilk and meat scrap, soybean oil meal (solvent or expeller process) in percentages of 15–22% in the rations of chicks or laying hens gave very satisfactory results. C. R. Fellers

Soybeans as a source of fat in the dairy ration. L. A. Maynard, Karl E. Gardner and Adrian Hodson. *N. Y.* (Cornell) *Agr. Expt. Sta., Bull.* 722, 30 pp.(1939).—The use of ground soybeans was favorable for milk production and general health. From 15 to 18% of the beans were used in the rations. The rations contg. 5.3–6.3% fat gave increased milk and milk fat yields over rations contg. 3–3.3% fat. Certain levels of fat intake are important from the standpoint of max. milk and fat secretion. The use of ground soybeans is a satisfactory and practical method of providing the needed fat. C. R. Fellers

Carcass studies on some grain-fed and garbage-fed hogs. E. H. Hughes and N. R. Ittner. *Food Research* 5, 83–7(1940).—The water content of the muscle from cured and smoked muscle from grain-fed hogs was lower than for similar muscle of hogs given garbage. There was a loss of 15% in the moisture content of muscle during curing and smoking. The av. *n* values of the fat were the same before and after processing. C. R. Fellers

The composition and canning properties of loganberries and blackberries. W. B. Adam. *Univ. Bristol, Fruit Vegetable Preservation Research Sta., Campden, Ann. Rept.* 1938, 32–8.—There was very little difference in the chem. compn. (acidity, sol. solids, insol. solids and pH) of the fruits of the closely allied loganberry and Phenomenal berry. Treatment of loganberry canes with a spray contg. Cu oxychloride increased the Cu content of the canned fruit from 1.3–2.0 to 4.2–4.3 p. p. m. The pH and the total acidity of loganberry fruits did not change appreciably during the season, but the total sugar tended to increase. There was no difference in the chem. compn. or canning properties of Black Diamond and Himalayan Giant blackberries. Significant increases in sol. solids, total sugars and pH and decreases in insol. solids and total acidity occurred during the ripening of blackberries in the edible state. K. D. Jacob

---

Characterizing soils [using app. for testing flour for baking quality] (Nitzsch) 15. Biochem. features of alpine fodder plants (Grebinskiĭ) 11D. Results of two years coöperative work on effects of fertilizers upon cabbage yields and quality (Vogel, *et al.*) 15. Method for detn. of carbonate [in baking powder] (Jones) 7. Preliminary study of anthelmintic activity in vitro of fresh pineapple juice (Asenjo) 11H. Effect of refining on digestibility of edible oils and fats (Menezes, Banerjee) 27. Condenser for solvent for extg. coffee (U. S. pat. 2,182,-183) 1. App. for irradiating foods (U. S. pat. 2,181,293) 4. Vitamin prepns. [for addn. to foods] (U. S. pat. 2,183,-053) 17.

Citrus Fruits and Health. Lakeland, Fla.: Florida Citrus Commission. 73 pp.

Descartes de G. Paula, Ruben: Alimentos—composição—valor nutritivo e dietético. Rio de Janeiro: Servico de estatística da previdencia e trabalho. 278 pp.

Deodorizing milk and cream with superheated steam. Elmer M. Davis (to Industrial Patents Corp.). U. S. 2,182,335, Dec. 5. App. is described, and a method which involves mixing preheated cream with superheated steam which is under substantial pressure and permitting the steam and volatile gases to escape in an open chamber.

Dried egg products. Roy C. Newton and Leon D. Mink (to Industrial Patents Corp.). U. S. 2,182,209, Dec. 5. A small proportion of glyceryl monostearate or other glyceryl ester of a higher fatty acid having a free glyceryl alc. group is used with dried egg material and facilitates mixing with water and various cake dough ingredients, etc.

Noncaking dried whey powder. David D. Peebles and Paul D. V. Manning (to Western Condensing Co.). U. S. 2,181,146, Nov. 28. An arrangement of app. is described, and a process for producing a dry noncaking whey powder in which moisture is removed from the raw whey and the lactose is caused to crystallize to form the final product, coagulation of the major part of the whey being effected before crystg. the lactose and the lactose crystn. being effected in the presence of the coagulated proteins.

Sausage casing. Leo A. Goodman (50% to Marcleph & Co.). U. S. 2,181,886, Dec. 5. A tube of knitted material is impregnated and coated with microporous vulcanized rubber. U. S. 2,181,887 relates to a method of making a sausage casing comprising the steps of coating a sheet of knitted fabric which is relatively stretchable in one direction with a rubber dispersion in which small amts. of compatible sol. bodies are uniformly distributed, coagulating and drying the coating, vulcanizing the coated fabric, treating with a solvent which does not affect the fabric or rubber but which dissolves the sol. particles to produce small pores in the rubber coating, and forming the coated fabric into a tube in which the relatively stretchable direction of the fabric is arranged circumferentially of the tube.

Laminated sausage casing. Charles T. Walter (to Industrial Patents Corp.). U. S. 2,182,188, Dec. 5. An inner layer of cotton cloth or the like and an outer layer of regenerated viscose cellulose or the like are used with an intermediate bonded layer of regenerated viscose cellulose. Cf. *C. A.* 33, 2242⁹.

Intensifying the color of fresh citrus fruits. John P. Ioannu. U. S. 2,182,965, Dec. 12. Fruits such as oranges are treated with SO_2 and then with an alk. compd. such as aq. NH_3 and then with an aldehyde compd. such as CH_2O.

Fruit concentrates. Norman M. Thomas (to Joe Lowe Corp.). U. S. 2,182,829, Dec. 12. A washed and seeded fresh fruit is reduced to a colloidal pulp in suspension in its own juice to form a sirupy mixt. which is mixed and heated with material such as an "intensified" juice of the

fruit and sucrose and the product may be used in frozen foods or as a sterilized purée, etc.

Food product from soybeans. Rupert G. Gates (50% to Charles L. Wickersham). U. S. 2,182,175, Dec. 5. Soybean flour is steamed to remove unpalatable constituents, mixed with water and minor proportions of edible adhesive and flavoring materials such as dextrin, sugar, salt, etc., to form a dough, the dough is cooked without completely dehydrating it, and the cooked dough is formed into pieces of desired size and shape, and these pieces are toasted.

Tea partially or wholly decaffeinized. Theodor Grethe. U. S. 2,181,549, Nov. 28. Leaf tea, from which the caffeine has been at least partially removed by a solvent such as methylene dichloride, but which still contains tannin set free from the caffeine-tannin complex initially present in the tea, is treated, as by soaking in an aq. soln. of gelatin, to form with the free tannin an odorless and tasteless compd. which does not unfavorably affect the taste or odor of the tea. Cf. *C. A.* **33**, 3020[1].

Supplemental feed for calves. James M. Coyner (to Armour and Co.). U. S. 2,182,171, Dec. 5. A mixt. is formed of bone meal about 30–50, $CaCO_3$ 10–30, Ca lactate 10–20, and Ca gluconate 10–20%.

13—CHEMICAL INDUSTRY AND MISCELLANEOUS INDUSTRIAL PRODUCTS

(PLASTICS, RESINOIDS, INSULATORS, ADHESIVES, ETC.)

HERMAN A. BRUSON

Organization for detection of war poisons. P. Degand. *J. pharm. Belg.* **21**, 895–902(1939).—A discussion of the administrative and tech. organization, including materials, for identification of poisonous substances. S. W. G.

Medical experience of the Americans with chemical warfare gases in the World War. Max Gerchik. *Protar* **5**, 3–6(1939); cf. *C. A.* **34**, 1093[2]. A. L. Kibler

Alarm devices for indicating the presence of dangerous gases and vapors. Chemisch-technische Reichsanstalt. *Z. ges. Schiess- u. Sprengstoffw.* **34**, 337–9(1939).—Upper and lower explosive limits are given for 18 combustible gases in mixtures with air, and dangerous and lethal concns. are given for 16 poisonous gases. The requirements which a satisfactory alarm device should meet are listed. All com. devices tested by the Chemisch-technische Reichsanstalt and by certain other testing stations are named and the principle upon which they operate are described briefly. A. L. Kibler

Collective protection. Louis Maricq. *J. pharm. Belg.* **21**, 731–6(1939).—A discussion of the treatment of air for poison-gas shelters. S. W. Goldstein

Combustion of phosphorus. Ernst Graf. *Gasschutz u. Luftschutz* **11**, 314(1939). This is a discussion of the use of P in war for producing screening smoke, as an incendiary and poison. Some exptl. work is also reported. In finely divided form P will spontaneously ignite at 10–20°, in larger pieces and with an impure surface at about 60° or over. The temp. of burning P was detd. by means of thermoelements to be 700–800°. The ignition temp. of wood is about 350° and the temp. of burning wood is about 1000°. It is difficult to kindle wood from a P flame because it becomes coated with phosphoric acid which affords some protection against fire. A. L. Kibler

Incendiary and bacteriological bombs. L. Millard. *J. pharm. Belg.* **21**, 913–18(1939).—A discussion of the effects of the bombs and means of combating them. S. W. Goldstein

Physiotoxicology of poison gases. L. Herlant. *J. pharm. Belg.* **21**, 815–24(1939).—The gases are classified and tabulated according to their toxicity. Symptoms produced by the gases of the different classes are given. S. W. Goldstein

Aerosols. G. Batta. *J. pharm. Belg.* **21**, 833–6(1939).—A discussion, based upon Stoke's law, of the behavior of toxic substances in liquid or solid phases when explosions of shells disperse them in the air. S. W. G.

Past and future development of some problems in the field of organic chemistry in the U. S. S. R. N. D. Zelinskiĭ. *Uspekhi Khim.* **8**, 949–55(1939); cf. *C. A.* **34**, 1093[6].—Z. discusses chiefly contact catalytic processes, hydrocarbons, alcs., acetone, petroleum, synthetic fibers and wood products. F. H. Rathmann

Studies on the production of artificial plastic masses from soybean protein. Nobuaki Wada and Yositaka Takaki. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 317–18(1939)(in German).—Oil-free soybean meal was extd. with 30-fold quantities of 0.3% Na_2SO_3 soln. and the protein, after pptn. from the clear soln. with dil. H_2SO_3, was washed, dried, powd. and mixed well with water (15–20% of the press-powder) and 10–30% of formalin (35% CH_2O), after which it was pressed at approx. 120° and at least 200 kg./sq. cm. pressure into transparent tan horn-like masses. Both H_2O and urea are suitable plasticizing agents; addn. of inorg. acids, bases and salts is not recommended. Phenol to some extent increases plasticity and in small amts. increases the imperviousness to water. George Ayers

Casting of thermoreactive plastic materials under pressure. A. A. Peshekhonov. *Org. Chem. Ind.* (U. S. S. R.) **6**, 207–14(1939).—The casting of resinol, novolac and carbamide molding compds. under pressure was studied and the tentative results are tabulated and discussed. The best results were obtained by casting of compds. with 150 mm. fluidity (Raschig) at 140–50° and 1500 kg./sq. cm. The phys. and mech. properties of the castings appeared to improve with greater section of the casting forms, though excessively large dimensions produced inferior results and rendered the operations difficult. As compared with pressed articles the cast products showed greater resistance to heat, lower permeability to water and inferior dynamic and static flexibility. Chas. Blanc

Plasticization of cellulose esters. S. P. Papkov. *Org. Chem. Ind.* (U. S. S. R.) **7**, 240–3(1939).—Most plasticizers can be broadly considered as solvents, whose solubilities obey the laws previously developed for the solns. of cellulose and its esters in liquid solvents (cf. Papkov, *et al.*, *C. A.* **32**, 765[3], 5682[4]). Chas. Blanc

Raw materials and technology of molded plastics. P. V. Kurytsin. *Org. Chem. Ind.* (U. S. S. R.) **6**, 201–2(1939).—A discussion. Chas. Blanc

Colored molding materials. E. M. Efimova. *Org. Chem. Ind.* (U. S. S. R.) **6**, 214–17(1939).—Colored pressed articles were made from the condensation product of PhOH and 12% hexamethylenetetramine. The resin was mixed with wood flour and 0.2–1% dye and 0–40% of mineral filler and the mixt. was pressed at 130–70° to give a disk 100 mm. in diam. and 2 mm. thick. The dyes used were Rhodamine B, Acid Orange 2 B, Auramine, Brilliant Green, Safranine and Formyl Violet, and the fillers were lithopone, MgO, ZnO and CaO. The stability of colors was tested by exposing the molded disks to daylight for 5 months and to the action of boiling water for 5 hrs. The most intense coloring was produced by Rhodamine and Safranine. The color effect depends more on the nature and proportion of mineral filler than on the coloring matter. Disks pressed at below 150° are poorly resistant to boiling water regardless of the compn. of molding powders. Independent of the coloring matter used all molded disks show dark discoloration in the sunlight. Chas. Blanc

New ways of obtaining resinous and film-forming materials from organosilicon compounds. K. A. Andrianov. *Org. Chem. Ind.* (U. S. S. R.) **6**, 203–7(1939).—Previously it was shown that the combined reaction of hydrolysis and dehydration of alkyltriethoxymonosilicanes affords com-

plex mixts. of high-mol. products formed by the siloxane bonds (*C. A.* **33**, 4193[4]). The glass-like resinous products are sol. in org. solvents. The solns. form films, which become infusible and insol. at room temp. Their elastic properties can be modified by the addn. of common plasticizers. The resin, when mixed with asbestos or wood flour, can be molded at about 200° to an infusible product. In their dielec. strength and resistance to heat and atm. elements these products are superior to the com. condensation products of PhOH, $PhNH_2$ and $CO(NH_2)_2$ with CH_2O and to Glyptal resins. This study of $EtSi(OEt)_3$ and iso-$BuSi(OEt)_3$ is being continued with other alkyl- and arylsubstituted esters of silicic acid. Extensive bibliography is given. Chas. Blanc

Measurement of electric conductivity in the control of drying of Neoleucorite. E. S. Medvedkov and V. B. Khaĭtser. *Org. Chem. Ind.* (U. S. S. R.) **6**, 218–23 (1939).—A modified Philippoff app. (*C. A.* **28**, 4633[4]) is described for measuring viscosity and elec. cond. of a Neoleucorite sample in the process of alk. condensation of PhOH and CH_2O and vacuum dehydration of resin. In the initial stages of cooking the sp. cond. and viscosity increase most rapidly and then the consts. change very little. During the vacuum drying at 78° the resistance rises from 100 to 2000–5000 ohms. The viscosity const. also rises rapidly. Resins with equal viscosities can have unlike conductivities. The possible explanation is that the processes of polycondensation and elimination of water proceed independently of each other. The relative velocities of the 2 processes dets. substantially the properties of final product. Chas. Blanc

Measurement of the cross section of rubber on insulated wires. E. F. Richter. *Elektrizitätswirtschaft* **38**, 767–8 (1939).—The av. cross-sectional area of insulation on insulated wires is calcd. from the vol. of EtOH displaced in a calibrated tube by a 20 cm. long section of the insulated wire (or shorter sections if the longer section is not available.) A special form of tube and buret is shown which permits successive detns. with high accuracy and slight time requirement. This method has the advantage over the microscopic method of giving the av. cross section rather than the cross section at one point.
R. W. Ryan

Benzine- and oil-resistant air-drying Glyptal enamels for electrical insulation. V. S. Kiselev, R. S. Kholodovskaya and M. I. Shabanova. *Org. Chem. Ind.* (U. S. S. R.) **6**, 232–5(1939).—Glyptal bases were prepd. from phthalic anhydride 37, glycerol 17.7, oil 45.25 and litharge 0.05% by heating the mixt. at 240–5° for 1.5 hrs. The oils used were raw linseed oil and cottonseed, sunflower and castor oils previously treated with an air current at 290° for 4 hrs. The insulating enamels were prepd. from 40–50% soln. of the base mixed with BuOAc, EtOAc and Fe pigment with and without the addn. of 10% nitrocellulose. The tabulated tests show that in their resistance to benzene at 25° and to transformer oil at 105° and the dielec. strength, the lacquers and enamels obtained from treated cottonseed oil are equal to the products derived from linseed-oil fatty acids. The best results gave enamels contg. nitrocellulose. All the prepns. from semidrying oils require the addn. of Pb-Mn linoleate dryer. Chas. Blanc

Synthetic materials as wire insulation. Winton Patnode, E. J. Flynn and J. A. Weh. *Elec. Eng.* **58**, 379–88 (1939); cf. *C. A.* **33**, 8329[9].—A review. 75 references.
C. G. F.

Temperature aging characteristics of class A insulation. J. J. Smith and J. A. Scott. *Elec. Eng.* **58**, T43–4(1939).—A review. Class A insulation lasts indefinitely if temp. does not exceed 90°. 16 references. C. G. F.

Measurement of dielectric loss at ultra high frequencies. K. Morita. *Electrotech. J.* (Japan) **3**, 267–71(1939).—A new method is described using parallel Lecher wires. In principle it is a reactance variation method.
C. G. F.

High-frequency dielectric-loss measurement by the varying gap method. T. Sakamoto and H. Uno. *Electrotech. J.* (Japan) **3**, 276–9(1939).—Dielec.-const. measurements by the pasted tinfoil method were not reliable in cases in which the capacity of the sample was fairly large or when the loss angle of the sample was exceedingly small. Here the varying gap method gave reliable data. The values for the dielec. const. by this method are 3.84 for quartz; 3.77 for bakelite; 4.70 for borosilicate glass; 6.38 for mica; and 120.5 TiO_2 for porcelain. C. G. F.

Elasticity of phenolic compounds. A. F. Shepard and L. A. Sontag. *Modern Plastics* **17**, 48, 78, 80(1940).—The effect of various fillers and moisture on the elastic properties of molded phenolic compds. is discussed.
A. F. Shepard

Wetting agents. H. K. Dean. *Wetting and Detergency Symposium*, Feb. 19–20, **1937**, *Brit. Sect. Intern. Soc. Leather Trades' Chem.* 25–39. **Wetting and deflocculation.** A. de Waele. *Ibid.* 57–66. **The mechanism of detergent action.** Conmar Robinson. *Ibid.* 137–51. **The solvent action of detergent solutions.** G. S. Hartley. *Ibid.* 153–62. **Some aspects of the action of the newer detergents.** E. T. Williams, C. B. Brown and H. B. Oakley. *Ibid.* 163–74.—A series of reviews.
M. M. Piskur

Determination of wetting coefficients. Allan Ferguson. *Wetting and Detergency Symposium*, Feb. 19–20, **1937**, *Brit. Sect. Intern. Soc. Leather Trades' Chem.* 11–17. **The Bartell cell technique.** S. H. Bell, J. O. Cutter and C. W. Price. *Ibid.* 19–24. **Apparatus for measurement of contact angles by the plate method.** C. G. Summer. *Ibid.* 41–52. **The determination of contact angles on thin wires or single textile fibers.** N. K. Adam and H. L. Shute. *Ibid.* 53–6. **Some factors in detergency.** Eric K. Rideal. *Ibid.* 197–202.—Reviews. M. M. P.

The significance of suspending power in detergent processes. J. Powney and R. W. Noad. *J. Textile Inst.* **30**, T157–71(1939).—The influence of various alkalies and long-chain detergents on the degree of deposition of suspended ilmenite particles on to cotton fabric was studied under various conditions. Simple alkalies such as Na_2CO_3 and NaOH cause an increase of deposition which can be attributed to a Na-ion effect rather than to a pH effect. In contrast, certain Na silicates and phosphates exhibit a very considerable protective action, which is attributed to selective adsorption of the anion. With Na hexametaphosphate and Na pyrophosphate the protective action was still appreciable at concns. as low as 5–10 parts per million. With Na laurate, Na stearate and Na oleate, the optimum protective action is reached at concns. which decrease rapidly with increasing chain length. The effect of added alkalies on the behavior of soap solns. was considered. Detergents of the long-chain alkyl sulfate type possess relatively low protective action. Ruby K. Worner

Polymerization and the production of new synthetics. B. A. Harold. *Am. Dyestuff Reptr.* **29**, 53–7(1940).—A review indicating the similarity in build up of the synthetic polymers developed in the textile, rubber and plastic industries. Corn, soybean and milk have been the sources of proteins from which fibers may be made. Methods of prepg. zein fiber from corn and casein fiber from milk are outlined. W. H. Boynton

Industrial minerals. Samuel H. Bolbear. *Eng. Mining J.* **141**, 95–6(1940).—Economic considerations are given to andalusite, sillimanite, asbestos, barite, bentonite, borax, chromite, diamonds, feldspar, lime, magnesite, mica, portland cement, potash, Sm bauxite and fluorspar. W. H. Boynton

Media for cutting of quartz and agate. A. P. Brestkin. *Trudy Tsentral. Nauch.-Issledovatel. Lab. Kamneĭ Samotsvetov Tr. "Russkie Samotsvety"* **1938**, No. 5, 3–16; *Khim. Referat. Zhur.* 2, No. 5, 33(1939).—A noninflammable substitute for kerosene was sought as a medium for cutting quartz and agate. Nonaq. media were more effective than aq.; this is attributed to the hydrophobic properties of these minerals, which facilitate the formation in nonaq. media of an adsorption layer (lowering the hardness). Addn. of surface-active substances to mineral oils had little effect on cutting. Spindle oil and transformer oil (possessing a small volatility and having no odor) can be used

as substitutes for kerosene. In polishing polycryst. quartz addn. of surface-active substances to aq. media increased the effectiveness 2–3 times. A similar addn. to nonaq. media had no effect on polishing. A considerable increase of the polishing effect was obtained by addn. to water of caustics, owing to the chem. sorption which destroyed the surface layer of the mineral.
W. R. Henn

Recent progress in the nonmetallics. Oliver Bowles. *Mining and Met.* **21**, 95–100(1940).—Important progress has been made in the introduction of cement-clinker coolers. There is a trend toward increased fineness of final product partly because of lower costs possible through the use of grinding aids. Thus 1 part of a mixt. of triethanolamine salts and highly purified sol. Ca salts of modified lignin-sulfonic acid with 3000 of clinker increases mill capacity 20–40%. New deposits, new plants and new technologic developments in the following are discussed: clay, feldspar, nephelite-syenite, lime, gypsum, fertilizer materials, refractories, bentonite, fluorspar, mica and S. A. H. E.

Japanese lacquer mixed with phenolic and alkyd resins. S. Simizu and T. Inai. *Electrotech. J.* (Japan) **3**, 230–4(1939).—Japanese lacquer has the formula: 3-$C_{15}H_{27}$-1,2-$(HO)_2C_6H_3$ (cf. Majima and Chō, *C. A.* **2**, 541).—As an insulation coating it lacks flexibility, is unstable electrically in the presence of moisture or water, and is susceptible to "lacquer pox." To overcome these defects, various plastics were added (see following abstrs.). When the lacquer (urushiol) was combined with phenolic resin (formanol 720 D) and alkyd resin (alkydal T) with the aid of toluene, the best proportion was found to be 3:4:3. The best baking temp. was 180° for 1 hr.; breakdown temp. was 186° for flexibility; 210° for HNO_3 (sp. gr. 1.38) resistance; 230° for 10 *N* NaOH; 290° for hardness; 327° for resistance to transformer oil; 327° to water; 365° to toluene; 365° for serious drop in dielec. strength. The coatings were applied to Cu plates 3 cm. × 8 cm. × 0.2 mm. C. G. F.

Japanese lacquer mixed with alkyd resin and asphalt. S. Simizu and T. Inai. *Electrotech. J.* (Japan) **3**, 234–6 (1939).—The best combination was found to be 3 of urushiol, 4 of alkydal "T" and 3 of asphalt; baked for 1 hr. at 150°. At about 200° the compd. lost its flexibility, resistance to acid and alkali, and insulating properties.
C. G. F.

Japanese lacquer mixed with phenolic and coumarone resins. S. Simizu and T. Inai. *Electrotech. J.* (Japan) **3**, 254–6(1939); cf. preceding abstr.—The best compn. was found to be 4 of Japanese lacquer, 1 of phenolic resin and 5 of coumarone. The best baking temp. was 160° for 1 hr. The breakdown temps. for the various properties were: insulating strength 270°; flexibility 183°; resistance to 10 *N* HCl 177°; to 10 *N* NaOH 195°; to oil 305°; to water 300°; to solvents 296°. C. G. F.

Japanese lacquer mixed with phenolic resin and amber. S. Simizu and T. Inai. *Electrotech. J.* (Japan) **3**, 280–2 (1939).—Samples of insulating varnishes were made by combining phenolic resin, amber and Japanese lacquer and the phys. and chem. properties of thin films studied. The amber was heated under reduced pressure and only the stable residue was used for the expts. The samples were baked at 150° for 1 hr. before testing. The best compn. was Japanese lacquer 5, phenol resin 4 and amber 1. A sharp drop in the breakdown voltage occurred upon heating to 320°; in flexibility at 170°; resistance to 10 *N* HCl at 213°; resistance to 10 *N* NaOH at 235°; to oil at 296°; to water at 315°; and to solvents at 342°.
C. G. F.

Methyl bromide as a rodenticide. C. E. Berry. *Bull. Dept. Agr., Calif.* **27**, 172–80(1938).—MeBr is effective in the control of rodents and of the insects harbored by them. There is no danger from fire. It can be used around buildings where poisoned baits cannot be used. The Mackie-Carter applicator is recommended for treating ground-squirrel burrows. C. R. Fellers

A methyl bromide dispenser for use in the fumigation of quarantined products. Charles A. Cain. *U. S. Dept. Agr., Bur. Entomol. Plant Quarantine* **ET-156**, 2 pp. (Feb., 1940). K. D. Jacob

---

Acetylation of wood cellulose and prepn. of cellulose acetate plastics (Davankov, Berlin) **23.** Silico-calcium [for smoke screens] (Bergeret) **4.** Industrial wastes from equipment manufacturers' viewpoint (Knowles) **14.** Derivs. of phenol obtained from cashew-nutshell oil [as plasticizers for lacquer materials] (U. S. pat. 2,181,119) **10.** Mixed triaryl phosphates [as plasticizers with cellulose esters or ethers] (U. S. pat. 2,182,309) **10.** Triaryl phosphates [as plasticizing agents for cellulose ether compns.] (U. S. pat. 2,182,817) **10.**

Chemical Industries. 13th ed. Edited by **D. M. Newitt.** New York: Chemical Publishing Co. 379 pp. $4.00. Reviewed in *J. Chem. Education* **17**, 98(1940).

Fourth Saranac Laboratory Symposium on Silicosis: An Official Transcript of the Fourth Laboratory Silicosis Symposium Held in Connection with the Trudeau School of Tuberculosis at Saranac Lake, N. Y. Edited by **B. E. Kuechle.** Wausau, Wis.: Employers Mutual Liability Insurance Co. 379 pp. $3.00.

Molding material. Carroll A. Hochwalt and Mark Plunguian (to Mead Corp.). Can. 386,619, Jan. 30, 1940. Concd. sulfite waste liquor is treated directly with caustic at boiling temps. and above at predetd. pressures, to remove objectionable sulfonic compds. and to provide a lignin product of alk. reaction having controllable m. p. characteristics.

Molding products such as steering-wheel rim coatings. Harry R. Husted (to Standard Products Co.). U. S. 2,182,400, Dec. 5. Various details of app. and operation, with differential temp. regulation for flow control of materials within a mold cavity.

Molding and polishing products such as automobile steering wheels. James S. Reid (to Standard Products Co.). U. S. 2,182,388–9, Dec. 5. Various details of app. and operation.

Dies or molds suitable for use with various materials. Paul C. Abouchar. U. S. 2,182,775, Dec. 12. Dies or molds are formed comprising at least 2 parts with an impression or mold chamber formed between adjacent surfaces of the parts, each of the opposed walls of the mold chamber being female exact reproductions for the surfaces of the articles to be produced, and the walls of the impression or mold chamber of the die parts consisting of electrodeposited iron having finished hardened surfaces.

Synthetic resins. Horace H. Hopkins and Frank A. McDermott (to E. I. du Pont de Nemours & Co.). U. S. 2,181,893, Dec. 5. A process of producing modified polyhydric alc.-polybasic acid resins that are clear and homogeneous and form rapid and hard drying films comprises heating glycerol, phthalic anhydride, linseed oil acids and China wood oil, the China wood oil constituting between 10–60% of the combined linseed oil acids and China wood oil content.

Synthetic resinous product. Winton I. Patnode (to General Elec. Co.). U. S. 2,181,739, Nov. 28. A hard, rigid, solid, resinous product suitable for elec. insulation is obtained by the copolymerization of styrene and 1–10% of allyl methacrylate (suitably by heating for 24 hrs. at 70–80°).

Synthetic thermoplastic resins. Philip H. Groggins, John T. Stearn and Benjamin Makower. U. S. 2,181,231, Nov. 28. Resinous products are obtained by esterifying a polyhydric alc. such as glycerol with an aliphatic hydroxycarboxylic acid such as lactic acid to give an ester which contains at least as many hydroxyl groups as were originally available in the alc. and then further treating this ester with stoichiometric quantities of a polycarboxylic acid such as sebacic acid to combine with all free hydroxyl groups.

Silicon-modified phenolic resins. Howard K. Nason (to Anderson-Stolz Corp.). U. S. 2,182,208, Dec. 5. Products suitable for molded articles or coatings, etc., are

obtained by treating *p-tert*-butylphenol, *p*-isoamylphenol or *p*-cresol with an alkyl orthosilicate, a Si tetrahalide, an alkyl-substituted Si halide or an aryl-substituted Si halide, and a vegetable oil such as castor oil (suitably by heating for 20 hrs. at 165–170°). Various examples are given.

Vinyl resin compositions. Kermith K. Fligor (to Carbide and Carbon Chemicals Corp.). U. S. 2,181,478, Nov. 28. A heat-stable compn. comprises a vinyl resin which contains a vinyl halide, and, as dispersed stabilizing material, about 1.2% of a metal stearate such as that of Cd, Ca or Pb and an alkali metal salt of a monobasic, monocarboxylic acid having not more than 2 C atoms to the mol. such as NaOAc about 0.3%.

Polyvinyl acetal resin. James G. McNally and Russell H. Van Dyke (to Canadian Kodak Co., Ltd.). Can. 386,580, Jan. 30, 1940. A polyvinyl compd. having a substantial content of acetate group is treated in the presence of a deësterifying medium and a strong acid, with butyraldehyde together with formaldehyde, acetaldehyde or propionaldehyde, added either simultaneously or successively. Cf. *C. A.* **33**, 3025[5].

Polyvinyl acetal resin sheets. Henry B. Smith and Donald R. Swan (to Eastman Kodak Co.). U. S. 2,182,359, Dec. 5. Transparent, rubbery sheets are formed of a polyvinyl acetal resin 100 parts together with at least about 40 parts of an "elasticizer" consisting of butyl or isoamyl carbamate 30–70 and dibutyl phthalate 70–30%. U. S. 2,182,360 relates to generally similar sheets contg. a polyvinyl acetal resin in which a predominating proportion of the acetal groups are butyraldehyde acetal groups, together with sufficient *o*-cresyl toluenesulfonate to give the sheet a rubbery character without substantially impairing its transparency. U. S. 2,182,361 relates to generally similar sheets of a resin contg. CH_2O acetal groups, together with benzyl H succinate. U. S. 2,182,362 relates to like sheets of a resin the acetal groups of which are acetaldehyde acetal or butyraldehyde groups, together with bis(2-(β-ethoxyethoxy)ethyl) formal; and U. S. 2,182,363 relates to like compns. in sheet form contg. bis(2-(β-butoxyethoxy)ethyl) formal with similar polyvinyl acetal resins. Cf. *C. A.* **33**, 2247[3] and following abstr.

Polyvinyl acetal resin sheets. Emmett K. Carver and Bruce E. Gramkee (to Eastman Kodak Co.). U. S. 2,182,371, Dec. 5. Transparent, rubbery sheets are formed of a polyvinyl acetal resin and tripropionin (suitably about 40% or more of the wt. of the resin). Cf. preceding abstr.

Hollow articles or vessels such as bottles from artificial resins. Heinrich Hoenig (to Richard Collins, John J. Sheridan and Philip M. Scher). U. S. 2,181,786, Nov. 28. A method of making open hollow articles or vessels having at least one constriction from artificial resins by molding under the action of heat and pressure involves spraying moldable artificial resin powder into a hollow mold through a constriction therein so as to line the interior thereof and then admitting fluid under pressure to the interior of the mold under the requisite temp. conditions, the fluid being in direct contact with the moldable compn.

Insulated electric conductor. Herbert A. Winkelmann (to Marbon Corp.). U. S. 2,181,632, Nov. 28. See Fr. 837,354 (*C. A.* **33**, 7437[1]).

Insulated submarine cable. Archie R. Kemp and Frank S. Malm (to Bell Telephone Laboratories, Inc.). U. S. 2,181,188, Nov. 28. A metal conductor such as one of Cu strands is surrounded by a highly magnetic metal such as a ribbon of Ni-Fe alloy with an overlying pressure-equalizing material of viscous or semiliquid polymerized isobutylene or the like, and a surrounding thermoplastic insulation such as rubber or gutta-percha.

Electric cable insulation. Fred R. Kaimer (to General Elec. Co.). U. S. 2,182,667, Dec. 5. A flexible, flame and moisture-resisting electrical cable of high-dielectric strength comprises a metallic conductor and insulation therefor comprising, in direct combination one with the other, at least one layer of vulcanized rubber compn. contg. halogenated aromatic C ring compd., the rubber compn. having a tensile strength of at least 1200 lb. per sq. in. and a min. stretch before rupture of a 2-inch section on a 6-inch test specimen of at least 400% and at least one layer of felted asbestos thereover and which is coated and impregnated with a compn. comprising halogenated aromatic C ring compd., such as chlorinated naphthalene. U. S. 2,182,668, relates to the use of an insulation comprising varnished fabric and inorg. fibrous insulating material such as felted asbestos with an intervening relatively thin sheet of material such as cellulose acetate or regenerated cellulose protecting the varnished fabric from abrasive action of the inorg. fibrous material.

Electric cables. Standard Telephones and Cables Ltd. Thomas R. Scott, Raymond C. Mildner and Thomas Edward David Menzies. Brit. 508,036, June 26, 1939. A barrier joint or termination is prepd. in an impregnated power cable by building up the insulation with fibrous tapes impregnated with polymerized material, e. g., polystryene, which may be admixed with plasticizers, e. g., rubber, or other polymers, e. g., polyisobutylene, polyethylene, basting the impregnated tapes with polymerizable material, e. g., monomeric or partially polymerized styrene, at intervals during the building up operation to cause them to adhere to one another and causing the impregnated tapes to overlap the protective sleeve of the cable.

Interpolymerization of fumaric esters and isobutylene. Heinrich Hopff and Gustav Steinbrunn (to I. G. Farbenind. A.-G.). U. S. 2,182,316, Dec. 5. Products of rubber-like or hard and elastic character suitable for use in making *lacquers* or *cable insulation*, etc., are obtained by the interpolymerization of isobutylene with fumaric diethyl ester or other fumaric ester in an aq. emulsion in the presence of O-yielding substances such as K persulfate and H_2O_2 which serve as polymerization catalysts.

Cyclohexylated chlorodiphenyl ethers. Frank B. Smith (to Dow Chemical Co.). U. S. 2,182,827, Dec. 12. Cyclohexylated chlorodiphenyl ethers varying in character from high-boiling liquids to hard, brittle resins, and suitable *for elec. insulation*, use as *plasticizers* with cellulose ethers or polystyrene, etc., are prepd. by the reaction of a cyclohexylating agent such as cyclohexene, cyclohexyl chloride, cyclohexyl bromide or cyclohexanol with a mono-, di-, or trichlorodiphenyl ether or a mixt. of such compds. in the presence of a condensing agent such as $AlCl_3$, BF_3, $FeCl_3$, $AlBr_3$, or an activated bleaching earth such as "Retrol" or "Tonsil." Various examples with details of procedure are given.

Adhesive. Albert J. Heberer (to Glidden Co.). U. S. 2,181,129, Nov. 28. An adhesive which is suitable for use on decalcomania transfers contains glue admixed with about 5–20% of a phosphatide such as lecithin, a plasticizer such as the mono-Bu ether of ethylene glycol and a water-sol. blending solvent such as glycerol. Cf. *C. A.* **33**, 3030[1].

Adhesives from dextrin. Philip D. Coppock. U. S. 2,181,782, Nov. 28. For rendering com. dry-roasted dextrin nonlump-forming when mixed with water, it is heated in a dry state for about 3–15 min. to about 70–130° between heated plates under a pressure of about 1 lb. per sq. in. and then ground to a powder.

Adhesive suitable for use on the edges of paper sheets. Walter P. Hilbourn. U. S. 2,182,399, Dec. 5. A mixt. contg. glycerol 5, Venice turpentine 5, white flake glue 32, and HOAc about 57 parts is subjected to gentle heating.

Adhesives suitable for use in making corrugated boxboard. Robert W. Maxwell (to E. I. du Pont de Nemours & Co.). U. S. 2,182,524, Dec. 5. An adhesive is prepd. contg. about 15–30% of unhydrolyzed starch such as corn starch, and a salt of deacetylated chitin in an amt. equiv. in its effect on the adhesive's viscosity to that of about 1.5–4.0% of an acetate of a typical deacetylated chitin a 5% aq. HOAc soln. contg. 5% of which typical deacetylated chitin has a viscosity of 880 poises.

Assistants for use in leather and textile treatments. Albert F. Bowles and Saul Kaplan (to Richards Chemical Works, Inc.). U. S. 2,181,476, Nov. 28. In various processes, use is made of an assistant which is a sulfuric acid deriv. of a hydroxy-ether ketone of the general

formula $R'CO(R''O)_nH$ in which R' is an alkyl radical having 3–20 C atoms, R'' is an alkylene radical and *n* is a number between 2 and 10.

Derivatives of substituted succinic acids. Walter Pinkernelle (to I. G. Farbenind. A.-G.). U. S. 2,182,178, Dec. 5. Succinic acids substituted in at least one of their methylene groups by at least one satd. or unsatd. hydrocarbon radical contg. at least 5 C atoms (suitably 8 or more C atoms) are converted into derivs. in which at least one acid hydroxyl group is substituted by an amino radical, to form derivs. of high capillary activity suitable for use as *wetting, washing, emulsifying, dispersing* or *permeating agents*, as by the reaction of isoamyl-, hexyl-, cyclohexyl-, heptyl-, octyl-, isododecyl- or pentadecyl-, or isononylenesuccinic acid anhydrides with NH_3 or amines such as monomethylamine, dibutylamine, diisopropylamine, octylamine, cetylamine, hydroxyethylamine, primary and secondary aromatic amines, such as aniline, toluidine, xylidine, chloroaniline, nitroaniline, ethylaniline, diphenylamine, α-naphthylamine, benzylamine, amines of the alicyclic series, such as cyclohexylamine, amino carboxylic acids, such as glycocoll and anthranilic acid, and also amino sulfonic acids, such as taurine, aminobenzenesulfonic acids, naphthylaminesulfonic acids, etc. NH_3 and the anhydride of isononylenesuccinic acid at 40–60° form a monoamide of dough-like character which gives off water when heated to 150–160° and forms an imide b_9 202–5°. Aniline and isododecylenesuccinic acid anhydride form a monoanilide which when heated to about 160° is converted into a phenylimide, $C_{22}H_{31}O_2N$, b_8 133–7°. Isononylenesuccinic acid monobutylamide is converted to an imide, $C_{17}H_{29}O_2N$, b_8 187 192°. Isononylenesuccinic acid β-hydroxyethylimide, b_7 200–212°. Isononylenesuccinic acid *m*-aminophenylimide b_9 268–275°. The dicarboxylic acid monoamide from isododecylenesuccinic acid anhydride and glycocoll, $C_{18}H_{31}O_5N$, is a yellow viscous mass which on heating to 150 200° is converted into isododecylenesuccinic acid-imidoacetic acid, b_{12} 260–5°. *p*-Aminophenol and isododecylenesuccinic acid anhydride form isododecylenesuccinic acid *p*-hydroxyphenylimide, $C_{22}H_{31}O_3N$, a dark brown, viscous resin. Isododecylenesuccinic acid anhydride heated with the Na salt of sulfanilic acid form a bright brown "glass," $C_{22}H_{30}SO_5NNa$. Isododecylenesuccinic acid anhydride and the Na salt of β-aminoethanesulfonic acid form a dark yellow "glass," $C_{18}H_{30}O_6NSNa$. Isononylenesuccinic acid anhydride and *N*-ethylaniline form the Na salt of isononylenesuccinic acid mono-*N*-phenyl-*N*-ethylamide, $C_{21}H_{30}O_3NNa$, a bright brown "glass." Isononylenesuccinic acid anhydride and diethylamine form isononylenesuccinic acid bisdiethylamide, $C_{21}H_{40}O_2N_2$, a dark yellow viscous oil b_{10} 195–205°. The Na salt of isotetradecylenesuccinic acid monobutylamide, $C_{22}H_{40}O_3NNa$, is a white powder.

Maltosamines. James H. Werntz (to E. I. du Pont de Nemours & Co.). U. S. 2,181,929, Dec. 5. By reaction of a mixt. contg. H, maltose, and NH_3 or an aliphatic primary or secondary amine, at a temp. of 20 50° and under a pressure of at least 15 atm., in the presence of a base-metal hydrogenation catalyst such as a Ni catalyst, products are formed such as: methylmaltosamine, a viscous liquid; octadecylmethylmaltosamine, a cryst. powder; 1-dodecylamino-1-hydroxymaltose; dodecylmaltosamine, m. (decompn.) 110–15°; 1-hexadecylamino-1-hydroxymaltose, m. 100–105°; hexadecylmaltosamine, m. 124–7°; mixed octadecyl- and octadecenylmaltosamines; mixed hexadecyl- and octadecylmaltosamines; maltosamine, a viscous sirup; 1-(*N*-methyl-*N*-heptylamino-1-hydroxymaltose, a sirupy product; and similar compds., those products having an aliphatic radical with 6 or more C atoms being suitable for use as *wetting, penetrating, deterging, dispersing, emulsifying, frothing* or *foaming agents*, alone or in various compds. and mixts. Numerous examples with details are given.

Oxidized chlorinated olefin polymers. Wm. J. Sparks and Clifford W. Muessig (to Standard Oil Development Co.). U. S. 2,181,158, Nov. 28. Products suitable for thermoplastic molding, either alone or mixed with fillers, dyes, pigments, etc., or for use with varnish gums, resins, solvents, etc., are produced by polymerizing an isoölefin such as isobutylene to a high mol. wt., oxidizing the polymer, as with O_3, and treating the oxidized polymer in soln. with Cl. Various details and modifications of procedure are described.

Polymeric esters. Wilbur A. Lazier (to E. I. du Pont de Nemours & Co.). U. S. 2,182,991, Dec. 12. Polymeric esters suitable for use in *making fibers, sheets, molded articles, etc.*, are prepd. by heating, in the presence of a dehydrogenation catalyst such as Cu chromite, a polymethylene glycol such as hexamethylene glycol, having at least 2 primary hydroxyl groups and at least 6 methylene groups interposed between the hydroxyl groups.

Polymerizing olefins such as isobutylene, from still gases. John A. Anderson (to Standard Oil Co. of Ind.). U. S. 2,182,512, Dec. 5. In a process of producing plastic hydrocarbon polymers, having a mol. wt. above about 1000 and suitable *for addn. to lubricating oils*, by the polymerization of isobutylene contained in hydrocarbon mixts. from cracking-still gases, which also contain a small amt. of diolefins, wherein the hydrocarbon mixt. is subjected to the action of an active metal halide catalyst such as BF_3 at a low temp. of about −40° to −70°, a method of increasing the mol. wt. and plasticity of the polymers involves removing the diolefins from the hydrocarbon mixt. before subjecting it to the polymerizing action of the catalyst by treating the mixt. with a reagent, such as Na, a peroxide, or maleic anhydride, which reacts with the diolefins but leaves the isobutylene and other hydrocarbons present substantially unaffected.

Polymerizing 1,2-dihydronaphthalene. Norman D. Scott (to E. I. du Pont de Nemours & Co.). U. S. 2,181,770, Nov. 28. A substantially infusible solid polymer is obtained by bringing 1,2-dihydronaphthalene into contact with an addn. compd. of an alkali metal such as Na in the proportion of 2 atoms with 1 mol. of a polycyclic aromatic hydrocarbon such as naphthalene (suitably at a temp. of −30°). U. S. 2,181,771 relates to a like polymerization of styrene. Cf. *C. A.* **33**, 9496[8].

Interface-modifying agents for detergent purposes, etc. Benjamin R. Harris. U. S. 2,181,890, Dec. 5. A method of converting a salt of an org. interface-modifying agent, having a lipophile group with at least 6 C atoms and a hydrophile group, such as lauryl K sulfoacetate, having relatively poor cold-water soly., into a different salt of greater soly. in cold water, involves prepg. a hot soln. contg. at least several percent of the initial material and passing the soln. in contact with a base-exchange material such as "Cristallite." Various examples with details are given.

Casein compositions. Charles Schwartz (to Hall Laboratories, Inc.). U. S. 2,182,357, Dec. 5. Casein and an alkali metal tripolyphosphate are used together in forming plastic setting compns. adapted for use as coatings, sizings, adhesives, etc.

Coating nails, tacks or the like with cellulose derivatives. James R. Thompson (to American Steel and Wire Co. of N. J.). U. S. 2,181,352, Nov. 28. A metal fastening for frictional insertion in wood or the like is provided with a hard, smooth coating comprising a base of ethyl-cellulose, nitrocellulose or cellulose acetate and contg. a resin effecting microscopic bonding of the coating to the fastening and to the material in which the latter is inserted, the coating being sterilized when applied to the fastening by a nontoxic alc. solvent, the base and resin of the coating both being nontoxic and the fastening being fit for holding in the mouth of the user, the coating being nongumming when the fastening is stored in warm or damp places. Cf. *C. A.* **33**, 7270[6].

Coating articles such as tin cans with resin compositions. Clifford J. Rolle (to Interchemical Corp.). U. S. 2,182,304, Dec. 5. An emulsion contg. a resin plasticizer such as "butyl cellosolve stearate" and a vaporizable liquid such as water is applied to the surface of an article such as a can and the article is bent while heated to vaporize the liquid, and a resin compn. is applied to the surface on which the plasticizer remains.

Composition for brush-coating belt pulleys. Joseph

Birnbaum (to Manhattan Lubricants Co.). U. S. 2,182,774, Dec. 12. A compn. for coating pulleys or the like to give increased traction between the coated surface and a belt contains nitrocellulose, a volatile solvent for the nitrocellulose, wood flour and iron filings.

Use of cellophane or the like as a wrapping material. Wilhelm B. Bronander. U. S. 2,182,113, Dec. 5. App. is described, and a method of sealing the wrapping material which may involve rendering it tacky and adhesive with a solvent such as ethylene glycol monomethyl ether and pressing the tacky surfaces together.

Diurethandiamine polymeric materials. Elmore L. Martin (to E. I. du Pont de Nemours & Co.). U. S. 2,181,663, Nov. 28. Products suitable for the *manuf. of continuous filaments*, etc., are produced from a diurethan of the general formula $(R'OOCNR'')_2R$ and a diamine of the general formul $(HNR'')_2R'''$ in which R and R''' are bivalent org. radicals having a chain length of at least 4 atoms of which the 2 terminal atoms are C atoms, R' is a univalent hydrocarbon radical and R'' is a univalent hydrocarbon radical or H, such as hexamethylenediamine and diethyl hexamethylenediurethan or the like (suitably by heating at 150-300°). Various examples with details are given.

Noncorroding "antifreeze" mixtures. Cyrus D. Eaton (to American Distilling Co.). U. S. 2,182,612, Dec. 5. Denatured alc. 100 cc. is used with a light mineral oil 1.0-4.2 cc., sulfonated castor oil 0.03-0.3 cc. and Na salicylate 0.1-0.4 g.

Magnesium oxychloride binders and compositions. Pierre J. Rougard. Brit. 507,982, June 23, 1939. A Th compd., e. g., $Th(SO_4)_2$, is incorporated as a substantial component of pigmentless Mg oxychloride binders, etc.

Restoring faded ink documents. Alexander Lowy and Clyde H. Campbell. U. S. 2,182,672, Dec. 5. For revivifying Fe-contg. faded characters on documents, they are treated with an acid soln. of $K_4Fe(CN)_6$, and the document is washed, and treated with a pptg. soln. such as one of a metal salt and subsequently washed again. A dye also may be used.

Etched intaglio printing plates. Charles L. Henderson (to Paper Patents Co.). U. S. 2,182,559, Dec. 5. An etched intaglio printing surface having in its printing surface ink-receiving recesses of substantially uniform depth and of area varying in accordance with the tone depth in the subject to be reproduced. The recesses are substantially rectangular in outline and substantially corresponding in location and arrangement to both the black and the white squares of a black and white checkerboard. The printing surface has continuous, solid, unetched portions sepg. all of the recesses and providing a continuous surface over which a doctor blade may ride, the unetched portions being in the form of two perpendicularly intersecting sets of spaced, parallel, continuous lines of material of sufficient width in the portions of the surface corresponding to the deepest tones of the subject to support a doctor blade and varying in width in the other portions of the surface substantially inversely proportional to the tone depth of corresponding portions of the subject, so that the full range of tones in the subject may be reproduced.

Hectograph carbon and copy sheet assembly. Richard V. Bowman (to Kee-Lox Mfg. Co.). U. S. 2,181,363, Nov. 28. With a sheet for use in making hectograph reproductions having a C coating on one side, there is used a copy sheet sep. from the C sheet and positioned against its coated surface, and the sheets are held in removable relation.

Hectograph blanket. Johan Bjorksten and Wm. Hoskins, Jr. (to Ditto, Inc.). U. S. 2,181,864, Dec. 5. The duplicating surface of a hectograph blanket is covered with a removable nonadhesive film comprising an algin or pectin such as a mixt. of starch or chlorinated starch and pectin.

Preserving textiles, rubber, paper, hydrocarbon oils, glyceride oils, essential oils, etc., from oxidative deterioration. Sidney Musher (to Musher Foundation Inc.). U. S. 2,181,765, Nov. 28. As a preservative treating agent, use is made of water-sol. antioxygenic material which may be prepd. from unbleached and unleached finely divided oats, maize or barley by mixing with water having a pH of between about 5 and 6.7 and at a temp. of about 52–74°, removing the undissolved residue, and concg. the resulting starch- and fiber-free liquor.

Cold-bonding waxy surfaces such as those of paraffined paper. Wm. I. Buckeridge (to Standard Oil Co. of Ind.). U. S. 2,182,513, Dec. 5. A method of cold bonding waxy surfaces comprises applying to one of the surfaces as a bond therebetween a coating of hydrocarbon plastic from the class consisting of isobutylene polymers having a mol. wt. of about 2000 to 15,000 and hydrogenated rubber, and pressing the surfaces together at ordinary temp.

Laminated material suitable for oil containers, etc. Everett G. Hughes (to Standard Oil Co. of Ohio). U. S. 2,181,811, Nov. 28. Laminated material comprises fibrous layers of sheet cellulose such as chip board or rag stock and, conforming accurately to the cellulose and having substantially the same rate of expansion and contraction, an oil-proof amorphous surface layer of Na silicate whose $SiO_2:Na_2O$ ratio is such as resultant from 5-40% of a 2:1 Na silicate, and 70–35% of a 3.25:1 Na silicate, and smaller amts. of gum arabic, glycerol and soap. Cf. *C. A.* **34**, 1475[5].

Wood composition suitable for use as a core with veneers. Charles Roman. U. S. 2,181,439, Nov. 28. Comminuted wood fibers are used with a binder consisting of a soln. prepd. from water 5 gallons, animal glue 8 oz., starch 4 lb., a mixt. of paraformaldehyde one oz., and 3 oz. of a mixt. formed of NaCl 19 and $NaHSO_4$ 75 parts.

Liners for cans, bottle caps, etc. Daniel M. Gray (to Hazel-Atlas Glass Co.). U. S. 2,181,481, Nov. 28. A flexible, nontacky compn. is used contg. a polymerized vinyl ester resin 14–17, tritolyl phosphate 4–6, and petrolatum jelly 0.35–0.6 parts (suitably with ethylene dichloride as a solvent).

Device for use in permanent waving of hair. Daniel Lakenbach. U. S. 2,182,636, Dec. 5. A sachet for permanent waving without the use of electricity comprises an envelope of soft, pliable, absorbent material such as paper contg. a mixt. of chemicals adapted to enter into exothermic reaction with a soln. which may be applied in drop form through an opening in a backing sheet with which the envelope is provided.

Smoke filter for cigarets. Robert S. Striefling. U. S. 2,181,614, Nov. 28. Within the mouthpiece end of a cigaret there is placed a smoke filter of fibrous material such as porous paper impregnated with an oxide or hydroxide of Ca, Mg, Al or Si.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Analysis of the sulfur-bearing waters of Carobbio (Parma). Giuseppe Illari and Maria Zucchetti. *Ann. chim. applicata* **29**, 467–74(1939).—These waters contain 2.5 cc. H_2S and 18.4 cc. of CO_2 per l. in soln. They also contain high Na and Ca and traces of Fe, Al, Sr and Ba. They are alk. bicarbonate sulfur-bearing waters.

A. W. Contieri

The fluorine content of Chengtu well water. Libin T. Cheng and Tung-Pi Chou. *J. Chinese Chem. Soc.* **7**, 36–9(1939).—Twenty-three samples of well water from different districts of Chengtu city (Szechuan) are analyzed and show a range of F content from 0.095 to 3.600 p. p. m. Only 4 samples show more than 1 p. p. m. of F.

Wm. H. Adolph

Simple dissolved-oxygen sampling device. Francis E. Daniels. *Public Works* **70**, No. 2, 20(1939); *U. S. Pub.*

Health Eng. Abstracts 20, S, 5(Jan., 1940).—Two methods for using single dissolved-O_2 bottles, in the absence of more complicated devices, for the collection of samples of water for dissolved O_2 are described. The first method consists of 1 glass tube within another and the 2nd method has the rubber stopper with 2 glass tubes with the seal outside of the neck. C. R. Fellers

Metropolitan Boston's new water-supply system. W. R. Brend. *Can. Engr.* 77, No. 20, 9(1939).—A review. Ann Nicholson Hird

Water purification progress during 1939. Norman J. Howard. *Eng. Contract Record* 52, No. 52, 49–51(1939).—A review. Interest was focussed chiefly on water pollution, higher standards of bacterial quality for finished waters, accelerated methods of treatment, and superchlorination for taste control. R. E. Thompson

New method of filtration. Anon. *Tech. sanit. munic.* 34, 40–1(1939).—Filtration of water after the addn. of an inexpensive colloid at the proper pH is proposed as a simple, effective and low cost treatment. The colloidal film of $Al(OH)_3$ or $Fe(OH)_3$ acts as a good bacterial filter. C. R. Fellers

Use of activated carbon to deliver a palatable unfiltered drinking water. Melvin H. Diven. *Taste and Odor Control* 4, No. 2, 1–2(1937); *U. S. Pub. Health Eng. Abstracts* 18, W, 15(Feb. 5, 1938).—Powd. activated C applied to a reservoir following treatment with $CuSO_4$ for algae control, effectively removed offensive odors and tastes from the water supply. While the $CuSO_4$ destroyed the algae, the C was required to remove the taste and odor. C. R. Fellers

Activated carbon and its use in water treatment. H. Descroix. *Tech. sanit. munic.* 34, 42–7(1938); cf. Helbig, *C. A.* 32, 8051[1]. C. R. Fellers

How to make certain that you can control tastes and odors in your plant, and how to obtain the greatest efficiency from your applied activated carbon. John P. Harris. *Taste and Odor Control* 4, No. 1, 1–3(1937); *U. S. Pub. Health Eng. Abstracts* 18, W, 14(Feb. 5, 1938); cf. *C. A.* 31, 4063[8].—Activated C makes possible a palatable, safe water which makes certain that the consuming community will not seek palatable water from unsafe sources. The use of activated C for odor and taste control is the most important development in water works practice since the use of Cl was introduced. C. R. Fellers

Ozone for water treatment. J. B. Klumpp. *Eng. News-Record* 124, 168–70(1940).—The lack of suitable equipment and the high cost of operation have retarded adoption of O_3 treatment in America. More efficient app. is now available. O_3 is generated by passing thoroughly filtered and dried air through the silent blue corona discharge created between dielectric plates at high voltage. The ozonized air, contg. approx. 0.5% by vol., is applied to the water under pressure and mixed with it by electrically driven agitators. The over-all power consumption is 9–14 kw.-hrs. per lb. of O_3 generated, depending on atm. conditions. At Whiting, Ind., a pilot plant of 3600-gallons per day capacity succeeded in producing a palatable water where all other chem. methods had failed to remove medicinal tastes caused by industrial wastes. A 4-million gallon per day plant is now under construction. The peak O_3 demand is estd. at 15 lb. per million gallons and the av. at less than 10 lb. With a max. energy demand of 14 kw.-hrs. per lb. and elec. energy at 2¢ per kw-hr., the cost would be $2.80 per million gallons. Older types of plants have been in continuous operation at Long Beach and Hobart, Ind., since 1930 and 1932, resp. R. E. T.

Application of experimental methods to the design of clarifiers for water works. Robert Walton and Thomas Dow Key. *J. Inst. Civil Engrs.* (London) 1939–40, No. 1, 21–48. Ann Nicholson Hird

Problems of sterilizing and clarifying water supplies. George B. Prindle. *Taste and Odor Control* 4, No. 1, 3–5(1937); *U. S. Pub. Health Eng. Abstracts* 18, W, 14 (Feb. 5, 1938); cf. *C. A.* 32, 1825[9].—Aeration is of very little value in removing org. odors. Superchlorination of raw water, followed by dechlorination of the filtered water, is effective only with relatively low odor intensities. The use of even small amts. of Cl in the raw water may at times seriously interfere with odor removal. Chloramines are less likely to interfere than Cl. C may be depended upon to remove any odor, providing enough can be fed. The point of C application should be either before or immediately after the water enters the mixing basin. Applying the C at the same point as the alum gives improved coagulation. C. R. Fellers

The use of sodium hexametaphosphate for softening of hard water. F. Nevolin and R. Shtern. *Maslobойno Zhirovoe Delo* 15, No. 5, 18(1939).—A method of prepn. of $(NaPO_3)_6$ is described and its effectiveness as a softening agent for water is confirmed. Chas. Blanc

Conditioning water for vapor heating boilers on Diesel-powered trains. Ray McBrian, *et al. Am. Ry. Eng. Assoc., Bull.* No. 414, 219–24(1939).—Vapor boilers as used for heating Diesel-powered trains, require water conditioning to prevent scale formation, pitting and corrosion. Steam at 200 lb. pressure is produced rapidly in continuous coils of steel tubing several hundred feet in length with no satisfactory means for mech. cleaning. Where proprietary compds. are used for water conditioning, frequent blowdown is necessary and also coils are cleaned every 30 days with passive acid. Condensate suitably conditioned by anti-corrosion treatment, is satisfactory but expensive. Exchange filters consisting of two filter beds of processed synthetic resins, for removal, resp., of both the cations and anions in the dissolved solids, are being used successfully at an operating cost of $0.34 per 1000 gal. for H_2SO_4, NaOH and wash water, to condition a water contg. 395 p. p. m. dissolved solids. Where raw water is low in Cl and SO_4, the use of H-zeolite in combination with Na-zeolite affords another means of securing a feed water low in dissolved solids. R. C. Bardwell

Use and application of chemicals for preventing deposit in pipe lines. R. M. Stimmel, *et al. Am. Ry. Eng. Assoc., Bull.* No. 414, 240–2(1939).—The pptn. of $CaCO_3$ in water lines as well as heaters, cooling coils, etc., can be prevented by the use of tannins or molecularly dehydrated phosphates such as Na hexametaphosphate. The optimum dose of tannins will vary from one pound of tannin to from 4000 to 15,000 gallons of water. Good results have been obtained with the hexametaphosphate using a treatment of one lb. to 60,000 gal., and in some cases as high as 120,000 gal., of water. R. C. B.

Comparative resistance of Bacillus coli and Bacillus typhosus to water treated with chloramines. Francis S. Smith. *N. Dakota Water and Sewage Works Conf., Official Bull.* 7, No. 1, 6–8(1939); *U. S. Pub. Health Eng. Abstracts* 19, W, 114(Dec. 16, 1939).—This article refers particularly to length of life of the organisms, methods of detection and treatment with chloramine to disinfect the water. Some strains of *B. typhosum* are even more resistant to Cl and chloramine than members of the coli-aerogenes group of bacteria. The effect of pH is discussed. C. R. Fellers

Sanitary aspects of the San Francisco water system. G. E. Arnold. *Civil Eng.* 9, 722–3(1939).—The watershed sanitation, storage, disinfection and lab. control are discussed. Ann Nicholson Hird

Progress report on the chemical treatment of lakes and streams with special reference to the origin and control of swimmers itch. *State of Wis., Comm. on Water Pollution,* July, 1939; *U. S. Pub. Health Eng. Abstracts* 20, SW, 1(Jan., 1940).—Schistosome dermatitis is known as "swimmers itch." The use of $CuCO_3$ for eliminating snails harboring cercariae from recreational bathing areas is described. The control of algal growths which cause offensive odors and tastes is largely by means of $CuSO_4$ in amts. so small that fish life is unaffected. Cf. *C. A.* 33, 8799[8]. C. R. Fellers

Water supply and sewage systems for Heron Bay Townsite. A. W. Lash. *Eng. Contract Record* 53, No. 1, 7–10(1940).—The water supply of the village of Heron Bay South, Ont., drawn from the Pic River, is purified by hypochlorination and pressure filtration. The sewage-treatment system consists of a septic tank and tile drains to a gravel percolation bed. R. E. Thompson

Sewage-disposal project of Buffalo, New York. Samuel A. Greeley. *Proc. Am. Soc. Civil Engrs.* **65**, 1341–65 (1939).—The engineering data accumulated during the design and construction of the intercepting sewers and the treatment plant are reported. The treatment consists of primary sedimentation, chlorination, sludge digestion and sludge incineration. W. D. Hatfield 1

Ontario sewerage plans for 1940. A. E. Berry. *Can. Engr.* **77**, No. 20, 7–8(1939). Ann Nicholson Hird

Sewage treatment coupled with irrigation. F. M. Veatch. *Eng. News-Record* **124**, 24–6(1940).—The recently completed sewage-treatment plant of Pueblo, Colo., is described. The effluent is discharged into the Arkansas River, the entire flow of which is appropriated for irrigation, and the principal objective of the plant is to prevent deposition of suspended matter in the river and irrigation canals. The plant, which has a capacity of 20 million gallons per day, consists of screens, grit chambers, pre-aeration tanks for grease sepn. and for mixing when a coagulant is employed, clarifiers of the center-feed, peripheral overflow type, heated sludge-digestion tanks equipped for gas collection and sludge drying beds. The sludge gas is utilized in gas engines, butane being used as a standby fuel. The digestion tanks are heated by circulation of the engine jacket water. The cost of the plant was $465,300, of which $68,300 was for connecting sewers. R. E. Thompson 2 3 4

Problems and trends in activated sludge practice. Robert T. Regester. *Proc. Am. Soc. Civil Engrs.* **65**, 1501–25(1939).—Pertinent data relating to the basic design and principal characteristics of 30 plants are included for comparative study. Operation results and techniques are discussed and the need for further research on the process is noted. W. D. Hatfield

How the moisture content of sludge affects digestion. Walter A. Sperry. *Public Works* **70**, No. 4, 14–15(1939).—Improvement in digester operation was obtained by reducing the pumping schedule to the min. needed to keep the tanks clean. This resulted in the thickening of the raw sludge and a reduction in vol. of the wet sludge. Data are given on the amt. and analysis of gases produced. Improved fuel gas was produced by adding used greases from plant units to the digester. George Papps

Sanitary engineering. Edward J. Cleary. *Eng. News-Record* **124**, 226–8(1940).—Developments in water purification, sewage treatment and refuse destruction are reviewed. R. E. Thompson 6

The history of sanitation in Chicago. Robert I. Randolph. *J. Western Soc. Engrs.* **44**, 227–40(1939). W. H. Boynton

Modern sanitation in Great Britain. David M. Watson. *J. Inst. Civil Engrs.* (London) **1939–40**, No. 2, 125–46.—A discussion. Ann Nicholson Hird 7

Typical problem in industrial sanitation. J. J. Bloomfield. *Proc. Am. Soc. Civil Engrs.* **65**, 1484–99(1939).—After a preliminary survey of the 36 plants in the U. S. engaged in the prepn. of hatter's fur, 5 were selected for careful studies. The major industrial hazards were found to be *dust* from the furs and *Hg vapors*. Suggested remedies are (1) by segregating those operations which handle untreated skins, 23% of the workers may be removed from the Hg-vapor hazard, (2) exhaust ventilation for cutting, brushing and blowing, (3) good natural or mech. ventilation decreased the Hg vapor assocd. with piling and shipping, (4) considerable exposure is attributed to handling Hg compds. in bulk and the storage of large quantities of Hg-treated furs, both of which should be stored in well-ventilated rooms away from the workrooms, (5) good housekeeping and general sanitation. W. D. Hatfield 8

Household fumigation with hydrogen cyanide discoids and with sulfur. Arnold Mallis. *The Sanitarian* **2**, No. 3, 11–12(1939); *U. S. Pub. Health Eng. Abstracts* **20**, PHA, 4(Jan., 1940).—Zyklon discoids, widely used for house fumigation purposes, are composed of diatomaceous earth impregnated with liquid HCN. Methods of fumigation and a discussion of safety factors are given. C. R. Fellers 9

Report on an experiment converting municipal wastes into organic fertilizer. J. C. Carter and Kamal El-Din Fahmy. *Ministry Pub. Health, Egypt, Sanit. Eng. Sect.* **1937**, 19 pp., Cairo Govt. Press; *U. S. Pub. Health Eng. Abstracts* **18**, GR, 6(Apr. 9, 1938).—House refuse was successfully composted with sewage or sewage sludge. The addn. of partially digested refuse to new composts materially accelerated digestion. The completely digested material was useful as fertilizer and was safe to handle from a public-health standpoint. C. R. Fellers

Industrial wastes from the equipment-manufacturers' viewpoint. C. L. Knowles. *Ind. Eng. Chem.* **31**, 1338–45(1939).—A review. Foster Dee Snell

Industrial water for textile industry (Schwabe) **25**. Toxicity of basic fuchsin for certain bacteria (Ritter) **11C**. Chemistry of waters beneath the Dnepr-Don depression and their connection with the size of oil deposits (Makov) **8**. Tube and header heat-exchange app. for use with H_2O, etc. (U. S. pat. 2,181,602) **1**. App. for cleaning filter beds (U. S. pats. 2,182,094–5) **1**.

Hastings, Anna B.: Biology of Water Supply. London: Trustees of the British Museum. 48 pp.

Meyer, Aug. F.: Der Wassermeister. Munich: R. Oldenbourg. 40 pp. M. 1.20.

Purification of water. Otto Liebknecht (to Permutit Co.). Can. 386,731, Feb. 6, 1940. Saline water is brought into contact with carbonaceous H zeolite to remove bases, then with a keratin material, such as wool, to remove free acids. The carbonaceous and keratin materials are regenerated periodically by treating with acid and with base, resp. Cf. *C. A.* **33**, 5959[8].

Treating water supplies by carbonation. Henry W. Doennecke, Emory W. Douglass and Carl O. Anderson (to Ozark Chemical Co.). U. S. 2,182,286, Dec. 5. A method of carbonating a large volume of water without appreciably raising its temp. involves effecting combustion of a gaseous carboniferous fuel beneath the surface of the water and discharging the combustion products directly into the water while causing relative movement between it and the point of discharge to effect suitable admixture.

Valve operating system (with a variable period time control) for water filtration plants and similar apparatus. Walter J. Hughes (to Infilco Inc.). U. S. 2,183,075, Dec. 12. Various structural, elec. and operative details.

Apparatus for preventing corrosion in water-heating equipments. Julia C. MacDougall and Leonard V. Sutton, Executors of the Estate of Archibald J. MacDougall. Can. 386,772, Feb. 6, 1940. An Al rod having insulating collars is suspended in the equipment, a Cu tube is mounted between the collars with openings at its ends to allow free circulation of water and gases, and a Zn tube closely embraces the Cu tube. This device establishes internal electrolysis with the heating equipment as the cathode.

Rotary distributor for sewage-treatment apparatus. Hubert Beddoes (to Pacific Flush Tank Co.). U. S. 2,181,932, Dec. 5. Various structural and operative details.

Apparatus for separation of grease from drainage, etc. Geo. J. Dehn. U. S. 2,181,263, Nov. 28. Various structural details.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

M. S. ANDERSON AND K. D. JACOB

Chemical studies of four soil types in the Louisiana sugar district. Nelson McKaig, Jr., and L. A. Hurst. *Proc. Intern. Soc. Sugar-Cane Tech.* **6**, 296–303(1938).—Correction. The first author's name is incorrectly given in the abstr. in *C. A.* **33**, 6503⁶. E. J. C.

Stabilized soil mixtures. E. A. Willis. *Roads and Streets* **83**, No. 2, 37–44(1940).—A summary of the results of tests on circular tracks obtained by the Public Road Administration on stabilized soil mixts. from studies of sand-clay, sand-clay gravel and crusher-run materials. W. also discusses the use of NaCl and $CaCl_2$ as water-retentive chemicals. Henri Marc 2

The physical, chemical and biological nature of soils in the olive groves of Ospedaletti and Alassio. M. Duggeli. *Vierteljahrsschr. naturforsch. Ges. Zurich* **84**, 119–36(1939).—Results of the examn. of 48 samples of soil from olive groves in different localities and under different cover crops are tabulated with respect to pH and content of H_2O, $CaCO_3$ and bacteria. The quant. estn. of soil bacteria was made by means of proliferation in 3 different nutrient media viz., gelatin, agar, and sugar and agar. John O. Hardesty 3

Local conditions of tropical West Africa, with special reference to the Cameruns. Wilhelm Grosskopf. *Kolonialforstl. Mitt.* **1**, 4–37(1938); *Neues Jahrb. Mineral., Geol., Ref.* II, **1939**, 135–8.—A detailed account of the formation of the red loam, of soil bleaching (podzolization), and of laterite formation is followed by a sketch of the chief soil types of Africa. C. A. Silberrad 4

Soil genesis from andesite in Grenada, British West Indies. F. Hardy and G. Rodrigues. *Soil Sci.* **48**, 361–84(1939).—Extensive chem. analyses and chem. and mineralogical examns. were made of representative materials obtained from a deep red earth profile overlying augite andesite as developed in Grenada, British West Indies. Bulk chem. analyses of various materials including parent rock and surface soil show that the combined SiO_2, Al_2O_3 and Fe_2O_3 vary widely in different products. SiO_2 was characteristically low in the laterite. Mineralogical examns. and dehydration curves were used to differentiate the various natural clay minerals. Typical clay minerals were used also for comparison. Three of the materials showed dehydration curves with remarkable similarity to the one for halloysite, although in these there is also some resemblance to kaolinite. The laterite curve is obviously modified by the content of gibbsite. The red earth may be regarded as the parent material of the surface soil. A theory is presented to account for gibbsite silication as an essential process in the transformation of primary gibbsitic laterite into secondary kaolinic red earth. This is based on colloid chem. interactions between descending acidic H_2O and alk. silica solns. comprising ground water, the level of which fluctuates with intermittent satn. An alizarin dye test is used for gibbsite, hydrous Fe oxides and clay minerals. The magnitude of dye absorption varied widely for different materials. Phosphate fixation tests showed that the surface soil, although the least active of the materials, is capable of fixing about 0.163% of its wt. of P_2O_5 or 1630 p. p. m. of P_2O_5. M. S. Anderson 5 6 7 8

New methods for the determination of the fertility of soils on the basis of their physicochemical characteristics. G. K. Davydov. *Doklady Vsesoyuz. Akad. Sel'sko-Khoz. Nauk im. V. I. Lenina* **1938**, No. 13–14 (22–23), 38–47; *Khim. Referat. Zhur.* **2**, No. 5, 54(1939).—In the soils investigated (ordinary chernozem, leached chernozem, rich chernozem and gray forest soil) the following relationships were found: (1) The greater the N content of the fraction < 1 μ the smaller is the need for N fertilizers. (2) This rule holds to a smaller degree in regard to P_2O_5. (3) Prolonged addns. of manure to the soils enrich the soil with N in the fraction < 1 μ. Attempts were made to prep. the soil for the sepn. of the fraction < 1 μ by treatment with ultrasonic vibrations of frequency 425,000/sec. This method is not as effective as the chem. method, but D. considers that it can be used successfully. W. R. Henn

Characterizing soils. W. v. Nitzsch. *Bodenkunde u. Pflanzenernähr.* **15**, 127–30(1939).—Because the colloids of soils vary widely in absorptive properties, tests such as hygroscopicity or heat of wetting are unsatisfactory in characterizing samples. The pycnometric detn. of "colloidal shrinkage" on a fresh sample by a procedure outlined (cf. N., *Pore Size in Soil and its Relation to Soil Treatment and Water Economy*, RKTL-Schr., H. 85, Paul Parey, Berlin), with the estn. of dispersable constituents, is recommended for the rapid examn. of soils necessary in advising farmers as to treatment. The former procedure is well adapted to serial investigations, the latter might be modified to use the special app. employed in *testing flour* for baking quality by washing out the starch, and so be made very rapid. Four references. C. J. S. 9

Annual report of the agricultural chemist to the government of Bengal for the year 1936–37. Gostabehari Pal. *Dept. Agr., Bengal, Ann. Rept.* **1936–37**, Pt. 2, 85–137 (1937); cf. *C. A.* **31**, 1927⁸.—The *germination of sugar-cane cuttings* was improved by soaking the cuttings in water for 8–24 hrs.; further improvement in germination was not obtained by adding ground limestone (1 lb.) to the water (25 gal.). *Soils* from the cinchona plantation at Mungpoo, Kalimpong to a depth of 18 in. were rich in N (0.179–0.412) and HCl-sol. P_2O_5 (0.10–0.32) and K_2O (0.89–1.51) but were low in HCl-sol. CaO (0.07–0.39%). Most of the coastal areas of the Chittagong district are going out of cultivation because of the gradual appearance in the soil of a condition known locally as "kasch," which adversely affects the growth of paddy. The top soil which usually extends to a depth of 3–12 in. is gray and friable. The next layer, usually 2–3 ft. deep, is full of chocolate-brown, semidecompd. vegetable matter spotted with sulfur-yellow, crumbly deposits. These yellow deposits, which occur mostly among the roots, are probably responsible for the poisonous effect. Samples of *mustard oil* available on the Bengal market showed sapon. values of 171.09–172.84 and I values of 98.74–99.86, as compared to values of 166.86–171.67 and 99.83–108.10, resp., for oils extd. locally from pure seeds. **Annual report of the agricultural chemist to the government of Bengal for the year 1937–38.** *Ibid.* **1937–38**, Pt. 2, 77–143(1938).—*Soil work.* "Kasch" soils from the Chittagong district were usually much higher in total N, org. matter and org. C than were the good soils in the same areas. In lab. expts., decompn. of the org. matter was not hastened by treating "kasch" soils under aerobic conditions with either saline or fresh water, with or without the addn. of $CaCO_3$; this was apparently because of the absence of aerobic bacteria from the natural soils. In lab. expts., the amt. of water-sol. K extd. from Dacca red soil was slightly increased by addn. of lime at the rate of 500–6000 lb./acre. *Mustard oil* extd. from different varieties of seeds tended to show characteristic I values and it was possible to calc. beforehand the I and sapon. values of oil prepd. from mixts. of known quantities of pure seeds. At vapor pressures above 4 mm., the *equil. moisture content* (*m*) *of wheat grain* corresponds to the equation $\log m = 0.18 + 0.7 \log pv$, where *pv* is the vapor pressure. K. D. J. 10

Method and procedure of soil analysis used in the Division of Soil Chemistry and Physics. W. O. Robinson. *U. S. Dept. Agr., Circ.* **139**, 21 pp.(1939).—A revision of U. S. Dept. Agr., *Circ.* **139**, issued Oct., 1930, in which methods are given for the detn. of Se and As in soils in addn. to the methods described in the earlier publication (*C. A.* **25**, 2504). W. H. Ross 11

The determination of lime requirements of soils. I. L. Skorik. *Doklady Vsesoyuz. Akad. Sel'sko-Khoz. Nauk im. V. I. Lenina* **1938**, No. 13–14 (22–23), 48–50; *Khim. Referat. Zhur.* **2**, No. 5, 53(1939).—Shake 20 g. of soil + 50 cc. of water + 5 g. of $CaCO_3$ in a mixer and collect the

liberated CO_2 in a buret (eudiometer) filled with a 0.05 N H_2SO_4 soln. About 20–30 min. is required for completion of the reaction. One cc. of CO_2 corresponds to about 1 ton of lime required per hectare. The accuracy of the detns. was ± 2 quintals/hectare. W. R. Henn

Estimation of potash in soils by the cobaltinitrite method. T. Rajagopalan. *Indian J. Agr. Sci.* 9, 745–53 (1939).—The cobaltinitrite method of estg. potash both volumetrically and gravimetrically was tested with reference to simple salts, artificial mixts. of various bases, acids, and HCl and citric acid exts. of soils. It was found reliable and quick within the ranges tried (3–53 mg. K_2O). The volumetric procedure especially may be very useful in detg. small quantities of potash, even below 1 mg., as are usually found in citric acid and NH_4Cl exts. of soils. The method is cheap and applicable in the presence of sulfates, phosphates and other bases and has thus distinct advantages over the platinichloride and perchlorate methods. A simple modified volumetric procedure for direct estn. of potash without removal of the bases in the HCl exts. of soils is also outlined. A. H. Krappe

An indirect method for determining the moisture content of soils at the "sticky point." Chao-Lin Feng. *J. Chem. Eng. China* 5, 74–8(1938); cf. *C. A.* 34, 1433[5].—A rapid and economical method for the detn. of the "sticky point" of soils, suitable for soils contg. not too large an amt. of sol. salts and giving results comparable with those obtained by methods hitherto used, is developed. The detn. is carried out as follows: About 50 g. or more of soil is first passed through a 2-mm. sieve and then placed in a shallow container contg. a small wire basket with holes about 1 cm. in diam. The surface of the soil is made smooth and plain by scraping it with a plate. Then, in the course of about 0.5 min., 1.0 cc. of distd. H_2O is dropped from a buret, the tip of which being 1.5 in. above the soil surface. After being allowed to stand for another 0.5 min., the mass is immediately removed from the wire basket by first lifting the basket from the container with a gentle tipping of the basket in order to let the dry soil filter through the bottom of the basket. It is then picked up with a pair of glass rods and weighed immediately. C. L. Tseng

Reliability of the proposed suction method of determining the moisture equivalent of soils. R. M. Pinckney and F. J. Alway. *Soil Sci.* 48, 403–11(1939); cf. *C. A.* 23, 3530.—The suction method for the detn. of moisture equiv. of soils is compared with the older centrifuge method on 113 Minnesota soils. These ranged in moisture equiv. from 1.5 to 90.6, in N content from 0.001 to 2.03%, and in pH from 4.7 to 8.1. The relations found are in general agreement with those reported by Bouyoucos, cf. *C. A.* 29, 6992[6], but they do not fully support his conclusion as to their reliability. Soils of loam or finer texture averaged about $^1/_{10}$ higher in moisture equiv. by the suction method than with the centrifuge, while sands were about twice as high by the former method. Soils intermediate between sands and loams showed variable concordance. Duplicate detns. by the suction method were much less concordant than those by the centrifuge procedure. The suction method may prove to be very satisfactory for comparing soils in 1 area, but for comparing soils of different areas the centrifuge method is preferable. M. S. Anderson

pH of soils in relation to moisture. M. R. Huberty and A. R. C. Haas. *Calif. Citrograph* 25, 6, 26–9(1939).—The data were obtained for soils of orange orchards under different irrigation practices. Preliminary work showed that the pH values for air-dry samples were consistently higher than those for oven-dry samples but in both cases the variation in pH values were uniform. Storage after oven-drying of soil samples increased the pH of the soil. Increasing the size of sample on which the pH detns. were made caused a slight drop in the pH value of 3 out of 4 soil samples tested. pH detns. in this work were made on 30 g. of oven-dry samples. Detns. on a 1–5 soil-water ratio showed that there was a progressive increase in pH with depth. With the probable exception of an Aiken clay loam there were marked increases in pH with increases in moisture content when the soil-water ratio was low, but at ratios of 1–10 the pH value might be lower than at the 1–5 ratio. pH values may undergo considerable change at moisture contents below the H_2O-holding capacity of the soil. Several soils were slightly basic at high dilns. but quite acid at low soil-moisture content. Direct soil pH measurements in the field gave lower values than those obtained from the 1–5 soil-water suspension. Marked changes were noted in the pH of calcareous soils at low and high dilns. Irrigation on a 2-week schedule gave lower soil pH values than a schedule calling for an irrigation every month. Dead algae tended to lower the pH of irrigation water, whereas when the algae were minute green forms exposed to light they tended to increase the pH. The pH of rainfall varied from 6.59 to 6.93. J. R. Adams

Three years' experiments on the water economy of the soil. L. Pozdena. *Bodenkunde u. Pflanzenernähr.* 15, 255–68(1939).—Plots on productive brown loamy sand only moderately supplied with humus, about 1% org. C and 1% $CaCO_3$, were variously fertilized with chemicals, specially fermented manure (Edelmist) and several humus fertilizers (cf. *C. A.* 31, 7576[1]). The connection between rainfall, H_2O in the soil at different depths, fertilization and yields of potatoes, oats and corn was studied. In so far as ground water did not supply the needs of the crops, there was a direct relation between rainfall, modified by seasonal distribution, and yields. The soil under potatoes tended to be more moist than under corn, from prevention of evapn. by the denser cover of the former. Fertilization tended to dry out the soil, but only as it caused a greater production of plant substance and better utilization of the available H_2O. The effects of the org. fertilizers and manure were the same as those of mineral fertilizers in this respect. Thirty references.
C. J. Schollenberger

Investigation of soils by the bio-indicator method. O. Pogrebnoĭ. *Visti Akad. Nauk Ukraïn. Sotsialist. Radyans'koĭ Respub.* 1938, No. 8–9, 61–5; *Khim. Referat. Zhur.* 2, No. 5, 53(1939).—The bio-indicator method does not replace the field, vegetation and chem. methods, but, being a mass method, it simplifies soil analyses in conjunction with them. W. R. Henn

Nonexchange ionic reactions in soils. S. G. Rydkiĭ. *Doklady Vsesoyuz. Akad. Sel'sko-Khoz. Nauk im. V. I. Lenina* 1938, No. 13–14 (22–23), 32–7; *Khim. Referat. Zhur.* 2, No. 5, 54(1939).—The object of the investigation was to study the hydrolysis reactions in soils. These reactions, when adapted to saline soils, can be regarded as a partial expulsion by H^+ of the exchange cations of the soil (Ca^{++}, Mg^{++}, Na^+) during the interaction with water, and an increase of pH which leads to an increase of their nonexchange adsorption by the soil. A dispersion of the soil mass is a result of this reaction. This conclusion was verified by the detn. of pH at different degrees of dilu. of the soil suspensions and by the potentiometric titration of soils with HCl and NaOH in the presence of NaCl. The increase or decrease of pH in the first expts. did not exceed the 0.5 limit in any soils except red soils, in which a dilu. of the suspension from 1:5 to 1:400 (1 g. of soil/400 g. of water) caused an increase of pH from 5.00 to 6.65. Thus, hydrolysis has an effect in the phenomena of dispersion of the soils, for practical purposes, in red soils only. In the potentiometric method of titration the suspension was first treated with a base, then titrated with acid and back-titrated with a base. The difference in the titration curves is regarded as a result of the preferential adsorption of OH^- or of H^+ by the soil. The magnitude of the difference of the curves can be regarded as an indicator of the character of the hydrolytic splitting of the soil colloidal complex. W. R. Henn

Agronomic evaluation of the "precipitate" from phosphorite. M. Kurakhtanov. *Trans. Sci. Inst. Fertilizers Insectofungicides* (U. S. S. R.) (*Sbornik Fosf. Udobr. i ikh Kach.*) 1938, No. 141, 156–66; *Khim. Referat. Zhur.* 1, No. 11–12, 73(1938).—Expts. with oats, peas and sugar beets on a no. of soils of different acidities show that the action of the "precipitate" from bone meal did not differ from the action of superphosphate from floated apatite. The "precipitates" from phosphorite contg. sesquioxides

had a smaller effect than had the superphosphate. A still smaller effect was obtained from the "residues" after the treatment of the "precipitates" with weak acids. Peterson's reagent cannot be used to det. the assimilation of P_2O_5 from "precipitates" rich in sesquioxides.
W. R. Henn

The effect of free iron oxide removal on some properties of soil colloids. S. J. Toth. *Soil Sci.* **48**, 385–401(1939). —Free Fe oxide was removed from soil colloids by the method of Drosdoff (*C. A.* **29**, 4865[4]). Various properties of the deferrated colloids were compared with the untreated materials. Deferrated colloids lost more SiO_2 and sesquioxides during electrodialysis than did the untreated colloids. The compn. of the sesquioxides varied, but more Al was always electrolyzed from the deferrated residues than from the untreated colloids. The Colts Neck colloid lost 4 times as much SiO_2 on electrodialysis after being deferrated as before, while the Sassafras colloid showed only a slight increase in loss. The SiO_2/Al_2O_3 ratio of the catholyte sediment varied between the limits 0.77 and 1.62. The sediments of the Cecil and Sassafras colloids had a higher ratio in the untreated sample while in the case of the Colts Neck and Penn colloids the higher SiO_2/Al_2O_3 ratios were obtained with untreated colloids. The removal of free oxides lowered the ultimate pH of the colloids without materially affecting the cation exchange capacity at pH 7. Removal of Fe oxide greatly decreased the capacity of the colloids to adsorb chloride and phosphate ions. However, the completely deferrated residue is capable of adsorbing approx. $1/2$ as much phosphate as the untreated colloid. In some cases the adsorption of phosphate ions increased the cation exchange capacity but in other colloids there was but little change. Neutralization curves of deferrated colloids were similar to the curves for original colloids but the residues possessed a somewhat lower buffer capacity. In general only slight changes were observed in the acidoid nature of soil colloids on removal of the free iron oxide. M. S. Anderson

The relationship between type of soil and the absorption of plant nutrients, based on results of pot experiments. F. Keller. *Landw. Jahrb. Schweiz* **53**, 786–92(1939).—Light soils are especially likely to be deficient in N; heavy soils are deficient in P. It is not correct to assume that in general heavy loam or clay soils are adequately supplied with K. In such soils the movement of the soil soln. is frequently slow and the K firmly held by the soil colloids is difficult for plants to acquire. Consequently, soils relatively rich in K may appear poor in this element and actually need fertilizers contg. K. E. O. Whittier

Partial sterilization of soils. M. Bogopol'skiĭ and O. Bershova. *Mikrobiol. Zhur. Akad. Nauk U. R. S. R.* **5**, No. 4, 119–60(1938); *Khim. Referat. Zhur.* **2**, No. 5, 55(1939).—Cl, $CaSO_4$, C_6H_5OH, etc., in amts. of 0.05–0.1% were investigated for the sterilization of soils. The effect of partial sterilization on the microflora of the soils was detd. by the change in the activity of the basic groups of bacteria. The activities of the ammonifying bacteria, the N-fixing bacteria and the bacteria that destroy cellulose are increased while the activity of the nitrifiers is decreased. The acidity (hydrolytic and exchange) and the soly. in water of mineral and partly org. substances (in particular of NH_4 salts and salts of H_3PO_4) are increased, while the amt. of nitrates in the soil soln. is decreased. The partial sterilization of soils increases the yield of tomatoes, oats and potatoes. W. R. Henn

The influence of cropping practices on some physical and chemical properties of soil. Frank Moser. *Soil Sci.* **48**, 421–31(1939).—Org.-matter content appears to be either directly or indirectly assocd. with the phys. properties that are important in soil structure. In a series of field expts. org. matter increased with legume and green manure crops and decreased with cotton-corn rotations. Cropping practices also had an influence upon dispersion ratio, suspension percentage and porosity. The suspension percentage and the dispersion ratio showed sufficient correlation with erosional behavior of soils under field conditions to be good indexes for predicting soil and water losses by lab. methods. M. S. Anderson

Pedology of Freiberg mining dumps. Gottfried Horn. *Mitt. Naturw. Ver. Freiberg* **3**, 30–3(1938). **Plants of the Freiberg dumps.** E. Lange. *Ibid.* 20–9, 45–6. **Old mining pools rich in plant life.** K. A. Jurasky. *Ibid.* 34–40; *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 120–1.—The Freiberg dumps are mainly derived from gray biotite gneiss, which readily weathers to form a fertile mellow loam contg. up to 3% chalk, 4% potash and 0.1% phosphates. The dumps from the Zn and Pb ores contain much sulfide and arsenide, and the decompn. products are very harmful to vegetation; as also are the dumps from the sericitized vein walls which are often impregnated with pyrite and arsenopyrite, and weather to an As- and S-contg. clay. Dumps from dolomite formations contain much less As and S, and produce generally satisfactory soils. C. A. Silberrad

The influence of overliming on boron deficiency. E. R. Purvis and W. J. Hanna. *Am. Fertilizer* **91**, No. 8, 5–7, 24, 26(1939).—The addn. of B alone to soln. cultures made alk. with lime water did not prevent overliming injury, but the injury was greatly reduced when the B was supplemented with the addn. of Mn. An overlimed Norfolk fine sandy loam soil retained more applied B after leaching than did the same soil in an unlimed state, and this retained B remained available to plants as evidenced by injury to subsequent crops. The evidence obtained indicates that overliming is not a primary cause of B deficiency. W. H. Ross

Occurrence of arsenic in soils and waters in the Waiotapu Valley, and its relation to stock health. I. R. E. R. Grimmett and I. G. McIntosh. *New Zealand J. Sci. Tech.* **21A**, 137–45(1939).—Sickness and death of cattle on drained swamp areas was assocd. with high As content in the soil and water. Co deficiency, called "bush" sickness, was excluded as a cause of death. Muds varied in As content from 0.0068–1.9% As; waters, from traces to 2.6 grains of As_2O_3 per gal.; and soils 0.0008–0.525% As. **II. Feeding experiments at Wallaceville.** L. W. N. Fitch, R. E. R. Grimmett and E. M. Wall. *Ibid.* 146–9.—The feeding of 0.342 g. As to a cow showed no increase in As in the milk. The feeding of about 1.36 g. of As over a period of several days resulted in death. As poisoning was obtained in cows fed limonitic and ferruginous muds contg. As from the Reporoa district. **III. Experiments, observations and analytical results on farm animals at Reporoa.** R. E. R. Grimmett, I. G. McIntosh, E. M. Wall and G. B. Jones. *Ibid.* 150–60.—The As content of clean pasture grasses from arsenical areas ranged from 0.6 to 23 mg. As_2O_3 per kg. of dry substance. The av. was 7.3 mg. This is not considered a likely source of cattle poisoning. Prolonged Co drenching in sick cattle was of no benefit, indicating that "bush" sickness was not involved. The As is derived by the cattle largely from water and mud in wet areas where As is concd. C. R. Fellers

Wilting coefficient and wilting percentage of three forest soils of the Duke Forest. Wilbur H. Duncan. *Soil Sci.* **48**, 413–20(1939).—Profile samples of Congaree clay loam, Georgeville clay and Orange loam soils gave ratios of moisture equiv. to wilting percentage varying from 1.57 to 5.65. Wilting coeff. is not a good measure of the lower limit of available H_2O in these 3 soils. M. S. A.

Seasonal water and nitrate leachings in relation to soil and source of fertilizer nitrogen. A second report on Windsor lysimeter Series "A". M. F. Morgan and O. E. Street. *Conn. Agr. Expt. Sta. (New Haven), Bull.* **429**, 43 pp.(1939); cf. *C. A.* **30**, 8472[2].—Particular attention was paid to the distribution of leaching during the several seasons, both as to vol. of drainage water and quantities of N lost from the soil. Nitrates are leached in direct proportion to the amt. of drainage water passing through the soil. Fifty % of the nitrate N residue was leached by 0.95 acre-in. of drainage water from the sandy soils and by 1.4 acre-in. from the loamy soils. NH_4 salts pass through the process of nitrification before being appreciably leached. In light sandy soils NH_4 salts may be leached to some extent before nitrification occurs. Urea is more readily leached from soils than either cottonseed meal or $(NH_4)_2SO_4$. Less than 66% of the N from cotton-

seed meal became available in the form of nitrates in the course of a year. On the other hand, about 80% of the N in $(NH_4)_2SO_4$ and urea is transformed to nitrates. The use of 200 lb. of N per acre, supplying 40 lb. immediately available as nitrates and the remainder as org. N, is good fertilizer practice in the Conn. Valley. Nitrate N applied to these soils before planting may often be leached away before the plant can utilize it. A summer rain of 1 in. or less rarely causes leaching of soil nutrients. On loam soils which have not received water for a week or more, a 2-in. rain causes no leaching. C. R. Fellers

Applicability of the Schuhknecht-Waibel apparatus for determining potash and phosphoric acid to the flame photometric and colorimetric estimation of potash and phosphoric acid in soil extracts and plant ashes. L. Schmitt and W. Breitweiser. *Bodenkunde u. Pflanzenernähr.* 15, 268–77(1939); cf. *C. A.* 33, 2436[6].—The app. has been improved by substituting a more compact galvanometer which requires no special support but magnifies its reading by projection to give as great sensitivity as with the mirror galvanometer formerly used. K_2O is detd. by atomizing the HCl soln. of ash, etc., into a C_2H_2 flame, and focussing through a light filter the characteristic double line of the K spectrum upon a photocell, the current from which is read upon the galvanometer scale. P_2O_5 is detd. by interposing a cell contg. the sample soln. with color developed according to Zinzadze into the path of the light beam and noting the decrease in the reading. In each case, the app. is standardized with samples of known compn. Several hundred detns. by either method can be made in a working day, with 98% of the K_2O and 95% of the P_2O_5 detns. agreeing within 2 mg. with the indications of standard chem. methods. The procedures are described in detail. C. J. Schollenberger

Comparison of Goy's single titration with results for hydrolytic or exchange acidity. H. Lacour. *Bodenkunde u. Pflanzenernähr.* 15, 246–50(1939).—A comparison on 325 soils of Goy's method I for CaO requirement, a single titration to pH 6.5 (cf. *C. A.* 31, 4033[3]), with the indications for hydrolytic or exchange acidity by Lemmermann's method (*Methoden für die Untersuchung des Bodens, C. A.* 28, 5916[9]) showed great variations and little consistency of either in relation to the pH values of the soils. Neither method has much basis in reason for the assumption that it will correctly indicate the optimum application of $CaCO_3$, and no consts. to fit all cases can be selected. Four references. C. J. Schollenberger

Microbiological investigation of the long-period experiment field of the University Farm at Mydlniki. J. Kleczkowska. *Polish Agr. Forest Ann.* 39, 322–39(in English, 339–40)(1937).—Examn. of the whole exptl. field revealed the presence of azotobacter when the pH of the soil was above 6.0; soils pos. with azotobacter gave 100% results in defining lack of P. Soils of pH less than 6.0 showed absence of the azotobacter which when inoculated into these soils gave 100% in showing lack of P and only 50% correct results when the P content was sufficient for good growth. Liming low pH soils did not cause a rapid appearance of the organism previously not present. C. T. Ichniowski

The adsorption of bacteriophages by the adsorbing complexes of soils. O. Bershova. *Mikrobiol. Zhur. Akad. Nauk U. R. S. R.* 5, No. 4, 161–80(1938); *Khim. Referat. Zhur.* 2, No. 5, 55(1939).—The adsorption of bacteriophages by 7 samples of soils (1 sample of peat) was investigated. The samples of one of the soils were satd. with different cations (H^+, NH_4^+, Na^+, K^+, Mg^{++}, Ca^{++}, Al^{+++} and Fe^{+++}). The adsorption of the soils is proportional to the amt. of humus in the soil. Heavy soils (chernozem) adsorb more bacteriophages than do the clay soils and, especially, more than the sand soils. Lowland peat adsorbs little bacteriophage. The adsorption increases in soils with cations H^+, NH_4^+, Al^{+++} and Fe^{+++} and decreases with Ca^{++}, Mg^{++}, K^+ and Na^+. The adsorption of bacteriophage depends on the org. part of the adsorbing complex of the soil. W. R. Henn

Oxidation of free ammonia by nitrifying bacteria. M. Kholodnil', V. Smalil' and R. Pikovs'ka. *Mikrobiol. Zhur. Akad. Nauk U. R. S. R.* 5, No. 4, 103–17(1938); *Khim. Referat. Zhur.* 2, No. 5, 54–5(1939).—Soil bacteria that are able to oxidize free NH_3 to HNO_2 and HNO_3 are not identical with the ordinary nitrifying bacteria, which oxidize NH_4 salts. However, in some cases the representatives of both groups of bacteria can use as sources of energy from the same substance, free NH_3 or NH_4 salts. Bacteria that oxidize free NH_3 can be cultivated on a solid substrate (silica gel satd. with a soln. of mineral salts without $(NH_4)_2SO_4$ with an addn. of chalk) as well as on a liquid substrate. When they are cultivated on silica gel, small yellowish brownish colonies are formed that can be easily detected at small magnification. W. R. Henn

Nitrogen fixation in rice soils. B. N. Uppal, M. K. Patel and J. A. Daji. *Indian J. Agr. Sci.* 9, 689–702 (1939).—Expts. with rice plants collected during the rainy season, isolations from soil samples by Ashby's method, and inoculation showed that *Azotobacter* plays an important part in the N recuperation of rice soils at Karjat. The organism is stimulated to greater activity when assocd. with the growing roots of rice plants, which seem to cause an increase in its efficiency of N fixation by bringing about a change in the reaction of the medium in the vicinity of living roots. The organism shows a marked periodicity probably because of external climatic influences in the soil, as it is very abundant during the monsoon but suffers a sharp decline in nos. in the dry period until it almost disappears from the soil in the cold season and during hot months. The microbial activity during the monsoon is reflected in an increased N content of rice soils. 15 references. A. H. Krappe

The influence of water and nitrogen supply upon the protein contents of barley varieties. (Experiments with second generation seed.) K. Nehring. *Bodenkunde u. Pflanzenernähr.* 15, 336–45(1939).—Barley grown in a previous expt. (*C. A.* 33, 1860[7]) was used as seed in a continuation of the work to det. the effects of differences in the N contents of the seed from the previous treatment upon the crop. The 6 times replicated plots of 25 sq. m. were fertilized at rates of 0, 27 and 45 lb. N/acre. Germination varied inversely with N in the seed, but otherwise there were no differences attributable to fertilization of the seed crop; the influence of the current fertilization was preponderant. The effects of N were similar to those previously noted; yields and crude protein contents were increased. The most pronounced effect was obtained with the normally high-N Abyssinian naked barley, which showed nearly as great increase in protein production as the high-yielding low-N variety Hado-Streng; the differences between the 2 high- and 2 low-protein varieties were less than in the previous crop. Control of the water supply by varying the width of drill rows had effects similar to those previously noted; planting in 15-cm. rows produced larger yields and showed greater effects from N fertilizer than were obtained from the same varieties in rows 20 cm. apart. Five references. L. Schmitt and W. Schineis. *Ibid.* 345–76; cf. *C. A.* 33, 1861[4].—The results of expts. similar to the foregoing are summarized: Only 1 variety of summer barley, normally high-N, showed any increase in ability in the second generation to produce more protein from increased N fertilization. The crops from high-N seed of 2 other varieties, one normally high-N and the other low-N, showed an inverse relation between N in seed stock and ability to utilize N fertilizer during growth. The latter seems to be a varietal characteristic; in varieties possessing it, the same is strengthened when the seed is rich in N, but otherwise the seed is weakened by high-N fertilization. In other respects, the effects of increased N supply for the seed crop were uncertain. High-N seed produced heavy grain; this quality in the second crop showed an inverse relation to yields of grain and straw and N contents. The greater water supply with 20-cm. rows was less favorable to increased yield of protein than the limited supply with 15-cm. rows; seed of some varieties grown in 15-cm. rows was weakened. As in the previous expt., with seed of normal compn. increase in available N increased yields and protein contents; 36

lb. N/acre seemed to be the optimum. Low-N varieties produced more protein to the acre because yields were greater. With 45 lb. N/acre applied, utilization was better with 20-cm. rows, because there was more water available. The crop from high-N seed showed less ability to utilize N supplied in fertilizer, but this difference tended to disappear as the N offered was increased. Differences in the seed caused by varied fertilization of the plants producing it were evident in differences in vol. wt. of the second crop with uniform treatment, but the limited water supply with 15-cm. rows was a more important factor for the second crop. Two references. C. Pfaff. *Ibid.* 377–82; cf. *C. A.* **33**, 1861[2].—Yields and compn. of barley varieties grown in pot tests to study the foregoing problem showed with uniform fertilization no significant differences attributable to effects of previous fertilization upon the seed stock. All lots of seed produced normal yields, with insignificant variations; that is to say, the 4 varieties tested showed their characteristic differences in yield and protein contents, independent of seed compn. The same indications as to the influence of water supply were obtained with the second generation crop as with the first. Two references. C. J. Schollenberger

Concerning the effect of several trace elements, boron in particular, on the growth of various cotton varieties. W. Schropp and B. Arenz. *Phytopath. Z.* **12**, 366–404 (1939).—Four varieties of Egyptian cotton were used in testing the effects on plant growth of B, Mn, Cu and Zn in Hoagland's A-Z nutrient solns. Expti. content of B ranged from 0.1–0.66 mg., Mn was 0.1 mg. and Cu and Zn each 0.01 mg., per l. of soln. Clear-cut effects of Cu and Zn were not obtained, although in the absence of these elements the shoot yield was higher, the root wt. lower, the chlorophyll content lower and the N uptake greater. The protein N portion of total N was greater in Zn deficiency than in Cu deficiency. Mn deficiency had assocd. with it chlorosis, depression of shoot wt., and a strong reduction of N uptake. Chlorophyll content reached its lowest level with Mn deficiency. It is uncertain whether Mn is indispensable for cotton. B is indispensable for cotton, its deficiency resulting in a lessened chlorophyll content and a general growth check and destruction of the shoot tip, with a strong thickening and watch-glass bending of the leaf blade. The N content of the shoot was not materially changed, the N uptake and protein production standing in close relation to the nutrient level and the duration of the expt. Injury symptoms of B deficiency are more marked with high nutrient level and long growth and likewise the action of higher B concn. is dependent on the level of the nutrient supply. Injury due to B deficiency is explained as NH_3 poisoning due to carbohydrate deficiency. The effect of B upon CO_2 assimilation and protein formation is indirect, as B prevents an undue swelling of plasma colloids, thereby favorably influencing the water relations. B brought in with Chile saltpeter completely prevented the appearance of deficiency symptoms. Of the cotton varieties studied Ashmouni was most tolerant, followed by Giza 12, Giza 7, with Sakel least tolerant to B deficiency. These variety differences are probably related to the climatic conditions of the typical culture regions of the 4 varieties. Merritt N. Pope

Borax for alfalfa in northern Idaho. W. E. Colwell and G. O. Baker. *Better Crops with Plant Food* **23**, No. 3, 9–11, 37–8(1939); cf. *C. A.* **33**, 7022[1].—Many of the soils in northern Idaho are deficient in B for alfalfa, and substantial increases in yields can be obtained by the addn. of borax either in the spring or in the fall, preferably at the latter time. Indications are that the protein content of B-deficient alfalfa is somewhat less than that of healthy plants receiving sufficient B for normal growth. J. R. Adams

Effect of the trace element vanadium on plant growth. S. Gericke and E. v. Rennenkampff. *Prakt. Blätter Pflanzenbau Pflanzenschutz* **17**, 17–22(1939); cf. Scharrer and Schropp, *C. A.* **29**, 6624–7.—VCl_3 at a concn. of 0.01% V in sand culture produced injury to barley growth whereas NH_4VO_3 gave favorable results at this concn. in sand and at 0.125% concn. in a soil rich in lime. In water-culture expts. 1 mg. V as $Ca(VO_3)_2$ gave better results than 0.1 mg., and 2 mg. further increased root growth, while 10 mg. was injurious to root and top; an increase from 0.1 to 1 mg. V as VCl_3 damaged growth. Water-culture expts. were made comparing the effects of $Ca(VO_3)_2$ and a com. fertilizer, Thomas phosphate, (I), contg. 0.6% V as $Ca(VO_3)_2$. One mg. V as I was much more favorable than as $Ca(VO_3)_2$, owing to the other constituents in I. However, the addn. of 1 mg. V as $Ca(VO_3)_2$ to 1 mg. V as I further increased growth, but the addn. of 10 and 20 mg. produced increasingly unfavorable results. E. J. S.

The action of trace elements in the border regions of the south Bavarian moors. J. Weigert and F. Fürst. *Prakt. Blatter Pflanzenbau Pflanzenschutz* **17**, 117–40 (1939).—Preliminary expts. (1935) indicated that the poor yields and partial crop losses of oats, barley, summer wheat and rye, potatoes, corn, hemp, beets and less of clover and other legumes in this area were due, not to deficiencies of the chief nutrients, N, P and K, but to the lack of B and Mn. Field expts. in 1936 showed that $CuSO_4$ dusted at 75 and 150 kg./ha., and sprayed in 3% soln. produced no appreciable effect on yield of oats, corn, hemp and potatoes. Addn. of 75 kg./ha., 150 kg./ha. and 10% soln. of $MnSO_4$ produced yields, resp., of 2, 3, 4 times the untreated in oats; 1.3, 1.7, 2 in oat straw; 1.3, 1.4, 1.4 in corn; 1, 0.9, 0.6 in hemp; and 1.3, 1.5 and 1.5 in potatoes. In beets, the yield was approx. doubled by addn. of 20 kg. borax, 10 kg. boric acid or B-contg. superphosphate. Lab. expts. showed that oats grown on local soil + $MnSO_4$ gave increased yields and were free of dry spot disease while plants on this soil + $CuSO_4$ or com. N-P-K fertilizer were diseased. Mn and Cu were not effective on potatoes in these lab. expts. Large and repeated field expts. in 1938 showed that the highest yield of potatoes was obtained by addn. of $MnSO_4$ at 60 kg./ha + com. fertilizer contg. N 45–50, P 60 and K 120. Addn. of $MnSO_4$ at 80 kg./ha. generally decreased the yield and $CuSO_4$ was inactive. The use of B as B-contg. superphosphate gave a less increased yield of potatoes but gave the highest yield of beets. Edwin J. Sciferle

Investigation of the individual action of calcium and phosphoric acid on plants. A. T. Kirsanov. *Doklady Vsesoyuz. Akad. Sel'sko-Khoz. Nauk im. V. I. Lenina* **1938**, No. 13–14 (22–23), 23–31; *Khim. Referat. Zhur.* **2**, No. 5, 56(1939); cf. *C. A.* **32**, 2891. The individual actions on barley of superphosphate, phosphorite and CaO were compared on podzol soils. In the first year superphosphate acted in the same manner as an equiv. amt. of Ca in lime. In order to verify the role of phosphorite as a Ca fertilizer vegetation expts. were performed with phosphorite + $Ca(OH)_2$ and with phosphorite separately. The action of superphosphate was considerably greater than that of phosphorite. Phosphorite in podzol soils acted at first like a lime fertilizer. With an increase of the degree of cultivation of the podzol soils the effectiveness of phosphorite as a source of P_2O_5 must decrease. The easily sol. phosphates are much needed for fertilizers. W. R. Henn

The effect of phosphorus and magnesium on the crop yield and on the quality of sunflower seeds, depending on the time of their addition. I. V. Mosolov. *Chemisation Socialistic Agr.* (U. S. S. R.) **1938**, No. 12, 92–4; *Khim. Referat. Zhur.* **2**, No. 5, 56(1939).—Sand-culture expts. showed that (1) P increased the yield of sunflower seeds (application at the beginning of the growth of sunflowers was more effective than during blossoming); (2) addn. of K before blossoming increased the yield of seeds and of oil (a max. yield of seeds was obtained by addn. of P during planting and of K during blossoming); (3) application of Mg together with P at the beginning of the growth of the sunflowers increased the content of oil in the seeds and its total yield. W. R. Henn

The effect of iron and aluminum oxides on the quality of Ammophos. Soil cultivation. L. I. Obolenskaya. *Trans. Sci. Inst. Fertilizers Insectofungicides* (U. S. S. R.) (*Sbornik Fosf. Udobr. i ikh Kach.*) **1938**, No. 141, 104–17; *Khim. Referat. Zhur.* **1**, No. 11–12, 72(1938).—Expts. with oats on an ordinary chernozem, on leached cherno-

zem, and on leached clay soils showed that effectiveness of fertilizers in decreasing order is Ammophos with small amts. of R_2O_3, Ammophos with large amts. of R_2O_3 and superphosphate, complex NH_4 phosphates of Fe and Al, phosphates of Al, and phosphates of Fe. The slightly sol. phosphates can be better evaluated on the second year after the fertilization. W. R. Henn 1

The effect of the composition and structure of iron and aluminum phosphates on the growth of plants. D. M. Khelfets. *Trans. Sci. Inst. Fertilizers Insectofungicides* (U. S. S. R.) (*Sbornik Fosf. Udobr. i ikh Kach.*) **1938**, No. 141, 76–87; *Khim. Referat. Zhur.* **1**, No. 11–12, 73 (1938); cf. *C. A.* **31**, 1717[6].—Cryst. $FePO_4.2H_2O$ and $AlPO_4.2H_2O$ are obtained by pptn. from soln. with $CaCO_3$ and by lime water at pH 2.8. Their soly. in Peterman's soln. is less than 50%. Similar phosphates are obtained at pH 3.6–4.2, by longer action of the reagents. Amorphous ppts. are first obtained, which are completely dissolved in Peterman's reagent. In expts. with oats on acid clay soils the amorphous RPO_4 was equiv. to "precipitate" and to double superphosphates. The effect of cryst. RPO_4 is only half that of amorphous RPO_4. By the action of NH_3 on solns. of Fe phosphate the following complex salts can be formed: (1) yellow-green $NH_3.2FePO_4.4H_2O$ formed at pH about 4.5, (2) colorless $NH_4H_2[Fe(PO_4)_2]$, (3) pink $NH_3[Fe(PO_4)_2].7H_2O$ formed at pH 3.8 and lower. (1) is slightly sol. in Peterman's soln., and is little available to the plants (according to the expts. with oats on acid clay soils); (2) and (3) are almost completely dissolved in the Peterman's soln. and, are more available than (1) in podzol, but are also comparatively little available in chernozem. W. R. Henn 2

The effect of ammonium humates on the availability of phosphates of the sesquioxides [iron and aluminum] to plants. D. L. Askinazi. *Trans. Sci. Inst. Fertilizers Insectofungicides* (U. S. S. R.) (*Sbornik Fosf. Udobr. i ikh Kach.*) **1938**, No. 141, 230–8; *Khim. Referat. Zhur.* **1**, No. 11–12, 75(1938).—The NH_4 humates increased the soly. and the availability for the plants of P_2O_5 from RPO_4 in the presence of $CaHPO_4$. This effect is attributed to a rupture in the bond between RPO_4 and $CaHPO_4$, with increase of soly. of $CaHPO_4$. W. R. H. 3

The effect of magnesium on the behavior of phosphoric acid in the soil. F. van der Paauw and Th. B. van Itallie. *Verslag. Landb. Onderzoek.* No. **45**, **A**, [7], 173–89(summary in German 189–90)(1939).—The addn. of MgO has no decided effect on the amt. of P taken up by the plant or its soly. in the soil. The addn. of Mg as phosphate to the soil shows after a short time the same soly. proportion as other H_2O-sol. phosphates. Pot and field expts. showed, that even with the addn. of a great variety of Mg salts, the amt. of P taken up by the plants was almost the same. J. C. Jurrjens 4

Manganese studies: California soils and citrus leaf symptoms of deficiency. H. D. Chapman, George F. Liebig, Jr., and E. R. Parker. *Calif. Citrograph* **24**, 427, 454; **25**, 11, 15(1939).—Pot tests showed that certain crops on certain California soils may be benefited by Mn applications. Mn-deficiency symptoms in the leaves of citrus cuttings were detd. Soil alky. often induced Mn deficiency. Despite the regular addn. of Mn to exptl. outdoor navel orange sand cultures, Mn deficiency developed when the pH of the nutrient soln. was maintained at 7.0 or above and disappeared when the pH was lowered. Analyses of leaves showing Mn-deficiency symptoms showed a Mn content of 2.7 to 4.9 p. p. m. while healthy leaves had 14 to 26 p. p. m. of Mn. J. R. Adams 5

Foliar diagnosis: Nutritional differences affecting the yields of potatoes from similarly treated plots. Walter Thomas and Warren B. Mack. *Proc. Am. Soc. Hort. Sci.* **36**, 573–89(1939); cf. *C. A.* **33**, 4728[9], 9514[3].—There was no direct relationship between the N content of the leaves and yield; the effect of N on the yield was governed by the presence of P and K. A relationship existed between the P and K in the leaves and yields. A low intensity of nutrition (sum of N, P_2O_5 and K_2O content of leaf as percentage of dry wt.) was always assocd. with low yields; but, owing to luxury consumption of K, high intensities were not always assocd. with high yields, although high yields were always assocd. with adequate intensity. The course of nutrition with respect to N, P and K during the growth cycle is described with the aid of graphs which show in trilinear coördinates the equil. between N-P_2O_5-K_2O in the chosen leaf at each sampling date for the different fertilizer treatments. Lawrence P. Miller 6

Losses caused by mineral phosphates in mixtures with sulfate of ammonia. P. A. Keiller. *Trop. Agr.* (Ceylon) **93**, 205–9(1939).—Mixts. of Ephos and $(NH_4)_2SO_4$ in ratios of 1:1 and 3:2 lost 1.7 and 3.4% of their total N, resp., when 0.5 lb. was spread in open pans for 15 days; 6.4 and 8.7% in 63 days. Mixts. contg. $(NH_4)_2SO_4$, Saphos and KCl in the ratio of 2.4:4 lost 4.8% of their total N in 9 weeks. Results were about the same when bone meal was substituted for Saphos. Two-ton lots of similar mixts. stored in bags gave negligible losses of N over a period of 2 months. **A note on the loss of ammonia from fertilizer mixtures.** Reginald Child, T. Eden and M. L. M. Salgado. *Ibid.* 210–12.—The above results were confirmed by similar expts. and it is concluded that the greater loss of N from the small samples used in the previous expts. (*C. A.* **33**, 7470[8]) was due to the more rapid uptake of H_2O in the very early stages of storage. John O. Hardesty 7

The influence of fertilizers upon the development of sweet clover (Melilotus albus). K. Nehring. *Bodenkunde u. Pflanzenernähr.* **15**, 130–3(1939).—Pot expts. with increasing applications of P_2O_5 and K_2O carriers to det. the effects upon yields, crude protein and coumarin contents (*C*) of sweet clover are described. Yields increased with fertilizer supplied, protein was increased by P_2O_5 but not by K_2O. The effects upon *C* were variable, permitting no very definite conclusions; generally, *C* in the first cutting was somewhat increased by the fertilizers, with little or no difference in the second cutting. Extreme values for protein in the dry sample were 14.0% in the first crop and 21.2% in the second; *C* varied 0.5–1.0 and 0.3–0.5%, resp. C. J. Schollenberger 8

Results of two years coöperative work on the effects of fertilizers upon cabbage yields and quality. F. Vogel. *Bodenkunde u. Pflanzenernahr.* **15**, 134–6(1939); cf. *C. A.* **33**, 7468[3].—An outline of the background and plan of the work described in the following abstrs.: **Cabbage experiments.** H. K. Möhring. *Ibid.* 136–9.—Tests on a fertile neutral loam garden soil indicated a slight but not significant increase in yield from chem. fertilizers alone, and a similar decrease from the same used with solid manure. The latter alone caused significant increases, and with liquid manure in addn. there was further improvement in yields; market quality declined as yields increased, and was adversely affected by com. fertilizers, alone and with solid manure, but the complete manure was worst in this respect. This neg. correlation between yields and quality is attributed to the prevalence of false mildew and bursted heads. **Experiments with cabbage for storage.** K. Reichelt and Fr. Weber. *Ibid.* 139–45.—Stable manure produced heavier yields, attributed largely to a specific effect in aiding the plants to recover from maggot injury. Com. fertilizers produced the largest percentage of full-sized heads, perhaps because the stand was thinner. There was no disease or pest injury the second year, and manure was again superior in effects, but yields were smaller because a less well-adapted variety was grown. **Fertilizer experiments with cabbage.** J. Reinhold. *Ibid.* 145–55.—Yields increased with length of growing season of the variety. Late varieties benefitted more from com. fertilizers, but the latter were not as good as manure, which seemed to enable plants better to survive adversities at an early stage, although manure was apparently injurious in one early variety. Since fertilizers alone noticeably improved survival from attacks by maggots, etc., the effect is attributed to improved nutrition in general. Data on decrease in dry matter and relative increase in ash contents with time of chopped cabbage allowed to rot in Petri dishes (Vogel's lab. test), to det. the effects of fertilization thereon, are shown graphically. The curves are similar and of the common log type with the former, 9

but manure had a specific influence to increase the slope with the latter. Rotting proceeded fastest with the unfertilized cabbage, and least rapidly with that receiving complete com. fertilizer; the influence of the latter was evident when used in addn. to manure. **Influence of fertilization upon yields and quality of cabbage.** F. Vogel. *Ibid.* 156–73.—In almost all respects, a combination of com. fertilizers and manure was preferable to either alone or no fertilizer; an exception was noted in tendency for heads to burst, and fertilizers alone produced the whitest cabbage. The unfertilized crop was highest in dry substance, 9.23%, that with manure and chemicals lowest, 8.52%, and with either alone, 8.9%. There are numerous illustrations of rotting tests and the growth of molds in juice from the crops, with discussion. **Cabbage quality tests.** J. Reinhold. *Ibid.* 173–9.—Samples grown in 6 localities, including those discussed above, were examd. for storing and cooking qualities (odor and flavor), both in Nov. and in Apr., after storage, to det. the effects of fertilization. Differences in culinary quality increased after storage, and were quite marked, but when averaged there was no consistent indication that quality had been influenced by fertilization. **The effect of fertilization upon the flavor quality of cabbage kept over winter.** J. Reinhold and A. Vogelmann. *Ibid.* 179–87.—Many factors enter into a judgment of culinary quality, and all must be considered. Tests on cabbage grown in 3 localities gave no consistent indication that fertilization had affected quality, when averaged. **Tests of the storage properties of cabbage.** K. Reichelt and Fr. Weber. *Ibid.* 187–90.—Cabbage grown in fertilizer expts. at several localities was stored in Nov. at the same place for comparisons of keeping qualities. In Apr., differences in color had disappeared. Some lots heavily fertilized with solid manure, and the same with liquid manure, showed a greater tendency to rot in storage, and it is concluded that this treatment may not be advisable for cabbage to be stored. **The dependence of sauerkraut quality upon fertilization of the cabbage.** F. Vogel, H. Rademacher and R. v. Hösslin. *Ibid.* 191–221; cf. *C. A.* 33, 2269⁷.—The cabbage grown in these fertilizer tests, at 6 and 3 places in the 2 years, was made into kraut by 2 firms, for tests under com. conditions. Notes on the behavior in fermentation and quality of the products are given. Considering all factors, it is concluded that fertilization of the cabbage with both manure and com. fertilizers is practically necessary to assure a good product. Cabbage grown without fertilization fermented "dead," that with manure alone was slightly superior to minerals alone, but not equal to the combination. **Chemical investigations on cabbage variously fertilized.** R. Balks and E. Pommer. *Ibid.* 222–33.—Detns. of ascorbic acid (*C*), total C, Na, Cl and other ash elements, crude and digestible protein, fat, fiber, N-free ext., etc., were made on samples of the cabbage grown in the fertilizer expts. at 3 places in 2 years, and the data are tabulated and discussed. There are wide and contradictory differences, and no very definite conclusions can be drawn. Manure seems to have increased *C* over the unfertilized crop, but the effect of fertilizer in this respect was scarcely inferior. N in complete fertilizer nearly always increased protein, but the effect of N in manure was uncertain. C. J. Schollenberger

Fertilizer experiments with tulip bulbs. J. Reinhold. *Bodenkunde u. Pflanzenernähr.* 15, 233–46(1939).—Plot and pot expts. are described to det. the value of standard com. and various "humus" fertilizers, stable manure and lime in propagating tulip bulbs. Mineral fertilization is in general advisable. N does not usually increase the crop of bulbs, but up to 10 g./sq. m. during the period of bulb growth has value in hastening the blooming when the same bulbs are forced. A part may be applied in Sept., when the bulbs are planted, a larger part in March and the remainder late in May. Nitrates are preferable to NH_4 salts, and if the soil is not very fertile, P_2O_5 and K_2O also are necessary. Fifteen g. K_2O/sq. m. as 40% manure salts is recommended; the tulip is not Cl-sensitive. The effect is on yield of bulbs rather than on forcing qualities. Superphosphate was the best P_2O_5 carrier in expts. on peaty soil, but in greenhouse culture others were as good; the effects of P_2O_5 were quickly evident in the better development of leaves; up to 12 g. P_2O_5/sq. m. is recommended. Two hundred g. $CaCO_3$/sq. m. had practically no effect on 2 soils at pH 6.5, nor were any differences seen in the forcing house. With more acid soils, liming is generally advisable, but not to exceed pH 6. The pH of the topsoil is important; in sandy soil at pH 5.5, many stalks broke down. Manure is not effective in increasing yields of bulbs, and is detrimental to forcing qualities; its only place in tulip culture is in application to a preceding crop. The com. humus fertilizers Huminal B and Stercoral with peat mull showed some value in tests on a light soil. Pot tests seem of no value in work with tulips; the bulbs require more room. The effects of fertilizers were more noticeable when the bulbs planted were small; large bulbs carry a stock of plant food sufficient for good growth even on poor soil. C. J. Schollenberger

Contribution to the study of the improvement of native tobaccos. Influence of fertilizer on their chemical composition. J. Stalé. *Landw. Jahrb. Schweiz* 54, 55–94(1940).—In acid soils, K_2SO_4 is particularly effective in improving the quality of tobacco; in lime soils, a complete fertilizer is most effective. E. O. Whittier

The action of deep-stall manure as affected by method, time and depth of covering, upon two different soils on one farm. H. Schurig. *Bodenkunde u. Pflanzenernähr.* 15, 284–335(1939).— The manure from 32 1200-lb. steers in a deep stall, fed 206 lb. beet tops and 6.2 lb. hay with 29 lb. wheat straw for bedding/head/day, was in part removed after 5–16 weeks. Samples showed 26–31% dry substance contg. 1.7–2.0% N, 26–30% thereof NH_3 and 73–69% protein. It was applied at 2 rates, 13.5 and 27 tons/acre, and at various times, plowed under deeply or shallow, promptly or after lying on the surface over winter, to plots on calcareous peaty sand and higher sandy loam. The plots were generously fertilized with P_2O_5 and K_2O, and some with N also to equal that supplied in manure. Potatoes and sugar beets were grown the first year; unfertilized barley was grown the second. There were also expts. with manure held between wire netting, buried deep or shallow in the soil and subsequently recovered for examn. Yields indicated that prompt covering after spreading manure is most important. Losses of N were less, with correspondingly more beets produced, when manure was spread on frozen ground in Feb. than on unfrozen ground in Nov., in each case plowed under in Apr. The loss in effect of manure lying uncovered over winter seemed relatively greater in the second year, as indicated by barley yields. Manuring in spring was always better than in fall; this is attributed not so much to the greater losses in the latter case as to the greater bacterial activity and sol. N content of manure after fermenting in storage over winter; after exposure over winter, the sol. constituents had been so far leached out that the remaining org. substance did not decomp. readily. With spring application, more NH_3 is available to the crop at a crit. period; spring plowing is more favorable, in that the soil is thereby more warmed and aerated than after lying plowed over winter. Prompt covering is most important with manure applied in spring, because drying by wind is then more rapid and causes greater losses of NH_3. Cultivation with spring manuring caused more of the N to be utilized the first yr., with a corresponding reduction in the second crop. The starch content of potatoes was reduced more by manure applied in spring, owing to the greater amts. of available N and Cl in the soil during the growing season; this effect was reduced by using a low-Cl K_2O carrier. The expts. intended to show differences in decompn. of manure buried in the soil were inconclusive, because these sandy soils were well aerated at all depths; they did show that a layer of manure can cut off capillary connection with the subsoil. Analyses of samples buried in Apr. and taken up in July showed that 15–23% of the org. substance and 8–10% of the total N had been removed; other samples buried since Dec. showed removals of 56–60 and 47–51%, resp. Disappearance of N was relatively greater in winter, of org. matter in summer. Manure was essential for max.

yields on these soils; plots with equiv. chemicals were less productive. 25 references. C. J. Schollenberger

Granulating phosphate fertilizers. J. N. Mackall and Mark Shoeld. *Chem. & Met. Eng.* **47**, 102–5(1940). E. H.

Disposal of orange waste as fertilizer. Sam J. Walker and Charles D. Samuels. *Calif. Citrograph* **24**, 350(1939).—The fluctuations in nitrate-N, P_2O_5 and K_2O were detd. on 3 different types of soil during a period of 60 days for both orange waste and dairy manure. During the first 20 days on a sandy loam soil and the first 30 days on a clay soil, the amt. of N that was made available was insufficient to satisfy the needs of the soil bacteria and there was a reduction in soil nitrates. Following these initial periods the nitrate-N was above the initial amts. and there was no fear of nitrate-N deficiency. The P_2O_5 and K_2O concns. showed a continued increase throughout the 60-day test period. Heavy use of orange waste on very sandy soils resulted in a 20 to 30% increased retentiveness of water. From these tests it is evident that orange waste is of equal value in all respects to dairy manure except for use in the spring of the year when addnl. N applications will be required. J. R. Adams

The composition of Ammophos obtained from raw materials rich in R_2O_3; methods of analysis. V. N. Panfilov. *Trans. Sci. Inst. Fertilizers Insectofungicides* (U. S. S. R.) (*Shornik Fosf. Udobr. i ikh Kach.*) **1938**, No. 141, 96–8; *Khim. Referat. Zhur.* 1, No. 11–12, 72(1938).—Ammophos contg. total P_2O_5 33, N 10.9, SO_3 15.0, and R_2O_3 18.3% was repeatedly leached with water, and the residue leached with a 2% soln. of citric acid or treated with a 10% HCl soln. Of the N 25.4% was insol. in water. Half the water-insol. N dissolved in 2% citric acid soln, all of it in 10% HCl soln. The water-insoly. of the N is attributed to the presence of complex salts of Fe and Al. It is proposed to det. total N according to the soly. of its compds. in a H_2SO_4 ext. A sample examd. contained 5.25% N in the form of $(NH_4)_2SO_4$, 3.8% in the form of the mono- and the di-phosphates of NH_4, and 2% in the form of $NH_4H_2[Fe(PO_4)_2]$. W. R. Henn

Effect of chloropicrin fumigation on nitrification and ammonification in soil. Frank L. Stark, John B. Smith and Frank L. Howard. *Soil Sci.* **48**, 433–42(1939).—In many respects chloropicrin behaves similarly to other so-called volatile antiseptics which have been tried for soil fumigation. Low dosages had but little effect on nitrate formation but applications as large as 9 cc. per cu. ft. greatly inhibited nitrification. In no case was ammonification inhibited. The data indicate that the increases in plant growth often reported to result from soil sterilization cannot be accounted for solely by the hypothesis that more N was made available. M. S. Anderson

Summary of work done under agricultural chemist and soil physicist, Agricultural Research Station, Sakrand, during the year 1935–36. Anon. *Dept. Agr., Sind, Ann. Rept.* **1935–36**, 118–33(Pub. 1937).—Paris green (applied at the rate of 40 lb. per acre, mixed with 10 times its wt. of sawdust), spread near the stems of the plants before the 1st irrigation, gave no control of *white ant attack on cotton plants*. *Effect of presence of NaCl at different stages of growth of wheat plants*. In pot expts., addn. of 0.3% NaCl to the soil before sowing had a very adverse effect on the growth of wheat. Comparatively little adverse effect was produced by adding NaCl after the seedling stage. K. D. Jacob

Detergents and wetting-out agents as assistants in plant pest control. H. Martin. *Wetting and Detergency Symposium*, Feb. 19–20, 1937, *Brit. Sect. Intern. Soc. Leather Trades' Chem.* 117–35.—A review. M. M. Piskur

Peach borer control with ethylene dichloride emulsion. Byrley F. Driggers. *N. Jersey Agr. Expt. Sta., Circ.* **396**, 1–2(1939).—The common peach tree borer, *Conopia exitiosa* Say, is well controlled by a 50% soln. of $CH_3.CHCl_2$ made up as follows: Prep. a stock soln. by adding with const. stirring 1 part by vol. of good grade fish-oil soap to 9 parts of $CH_3.CHCl_2$. When the emulsion is complete add 8 parts of water to bring the final stock emulsion to 50%. For trees 3 or more years old use 3–5 gal. of the stock emulsion with 5–7 gal. of water per tree. C. R. Fellers

Control of Japanese beetle on ornamental plants. Clyde C. Hamilton. *N. Jersey Agr. Expt. Sta., Circ.* **387**, 1–4(1939).—A mixt. of Pb arsenate and fish oil used as a spray is an effective spray material if used about July 1st when the beetles first appear in considerable nos. To prep. the spray, add 6 lb. powd. Pb arsenate and 1 pint of menhaden fish oil to 100 gal. of water and stir into a good emulsion. Powd. derris and cubé roots also contain toxic substances which are very repellent to the beetles. These powd. roots should contain not less than 4% rotenone and 16% total extractives. A satisfactory emulsion consists of 4 lb. derris or cubé powder, 4 lb. rosin residue emulsion and 100 gal. of water. C. R. Fellers

The grasshopper outbreak of 1939. Stewart Lockwood. *Bull. Dept. Agr., Calif.* **28**, 393–411(1939).—The most satisfactory bait for the 4 species of grasshoppers most commonly found in Calif. is composed of 1 quart of Na arsenite dild. with 12–16 gal. of water and then mixed with 100 lb. bran or equiv. of bran and sawdust. Beet pulp can also be used as an absorbent substance. C. R. Fellers

Destruction of alfalfa weevil (Hypera variabilis) by fumigation and other means. D. B. Mackie and W. B. Carter. *Bull. Dept. Agr., Calif.* **28**, 466–70(1939).—When fumigated under tarpaulins the weevils in baled alfalfa hay were killed by MeBr used at the rate of 1–2 lb. per 1000 cu. ft. of space with an exposure of 6–12 hrs. C. R. Fellers

Hypera brunneipennis and its destruction in baled hay by fumigation. D. B. Mackie and W. B. Carter. *Bull. Dept. Agr., Calif.* **28**, 387–92(1939).—This alfalfa weevil is destroyed in baled hay by a fumigation with MeBr in concns. of 1 lb. to 1000 cu. ft. of space. The residual Br in the hay is about 10 p. p. m. C. R. Fellers

A new method of combating chrysomelids on rice in Madagascar. C. Frappa. *Riz et rizic.* **12**, 33–9(1938); *Rev. Applied Entomol.* **27A**, 664–5.—Crude oil, to which 5% cresyl had been added as a spreader, was distributed over the water of rice fields at the rate of 22 pints/acre. The injurious beetles, *Hispa gestroi* Chap. and *Trichispa sericea* Guér., were beaten down to the oil by dragging a rope across the rice. Edwin J. Seiferle

Further studies on the control of bean rust, with some reference to the prevention of chocolate spot of beans. A. F. El-Helaly. *Ministry Agr., Egypt, Tech. Sci. Service, Bull.* No. **236**, 24 pp.(1939); cf. *C. A.* **33**, 7030⁴.—Spraying with 0.5% Bordeaux mixt. was the most satisfactory method for controlling both chocolate spot (caused by *Botrytis fabae*) and rust of beans. The effectiveness of the spray was not greatly affected by variations in the ratio of $CuSO_4$ to lime. Bouisol, a proprietary Cu fungicide, also gave good results. The plants should be sprayed at the first appearance of disease and further applications should be made at intervals of 4–8 weeks. Lime-S was not so effective as the Cu sprays. Wettable S and Kolofog S sprays and a S dust (Kolodust) were ineffective. K. D. Jacob

Further spraying experiments for the control of apple scab [Venturia inaequalis] in 1937 and 1938, with some observations on the disease. Robert McKay. *J. Éire Dept. Agr.* **36**, 42–72(1939); cf. *C. A.* **32**, 5987¹.—Three to 4 applications of lime-S or of Bordeaux mixt. applied pre- and postblossom gave very satisfactory control of scab. The superiority of Bordeaux mixt. over lime-S in giving more lasting protection to the foliage appeared to be due in part to its direct effect on the foliage, as distinguished from obvious injury such as brown dead spots or purple blotches; the leaves became hard in texture and took on a mature appearance soon after applications of Bordeaux mixt. following petal-fall. Sch. 1132 (a proprietary Cu fungicide) caused considerable injury to the foliage and fruit of Allington Pippin and Newton Wonder apples. Although the results from micronized S for scab control were inconclusive, the material seemed to be safe for postblossom application on a no. of varieties which will not stand lime-S after flowering. K. D. Jacob

Weed control in tulips. J. Hargrave and F. C. Thompson. *Agr. Inst. Expil. Sta., Kirton, Rept. Bulb Expts.* **1936**, 45–7.—The best control of weeds was obtained by spraying the plots in Jan. or March with a soln. of 10–20 lb. $NaClO_3$ per acre applied in 150 gal. water. The larger application of $NaClO_3$ caused some slight damage to the tulips. Weed growth was reasonably well controlled by a dry application of com. $CaCN_2$ (5 cwt. per acre) made in Jan.; there was no apparent damage to the foliage. K. D. Jacob

Manganese deficiency as the cause of marsh spot of peas. Helena L. G. de Bruyn. *Tijdschr. Plantenziekten* **45**, 106–20(1939); *Rev. Applied Mycol.* **18**, 777.—Pathological symptoms of marsh spot of peas due to Mn deficiency developed less rapidly in acid solns. where the Mn is more readily available than in alk. solns. but pH of the soil is of secondary importance as the disease develops under both conditions. Under field conditions the highest incidence of marsh spot occurs among the heaviest peas, but in cultures the lightest (under 400 mg.) suffered most (41.5%) and the heaviest (over 500 mg.) least (19.5%). Oden E. Sheppard

Stem-black disease of apple in Kumaun. P. K. Dey and U. B. Singh. *Indian J. Agr. Sci.* **9**, 703–10(1939).—A description of the stem-black disease of apple by *Coniothecium chomatosporum* Corda, a fungus which can enter the stem only through wounds, is followed by a detailed cultural study of the fungus. The latter is slow in growing and does not produce conidia in any of the media tried; only chlamydospores are formed. Painting of the pruned surfaces with a paste of 2 oz. each of red lead and copper carbonate and 100 cc. of raw linseed oil effectively controlled the spread of the disease. 6 references. A. H. K.

Studies on the conditions essential for life of the fungus Monilia fimicola Cast. et Matt. and its relations to mushrooms. K. Flachs and M. Walter. *Prakt. Blatter Pflanzenbau Pflanzenschutz* **17**, 98–114(1939).—Expts. were made to det. the optimum growth conditions of *M. fimicola*, "white plaster mold," parasitic on cultivated mushrooms, and to compare them with those of the host. A series of artificial media was prepd. by mixing 1 kg. of nutrient medium with 2 l. H_2O, heating to 50–60°, decanting after standing overnight, and adding to 1 l. of this ext. 1 l. H_2O and 40 g. agar-agar. The nutrient media were: well-rotted horse manure (I), carrot (II), sugar beet (III) and beans (IV). These prepd. media were further varied by addn. of a "complete fertilizer" (V), i. e., 0.1% $(NH_4)_2SO_4$, 0.1% K_2HPO_4, 0.05% $MgSO_4$, 0.2% NaCl and 0.04% $FeSO_4$. Growth of *M. fimicola* on the artificial media alone decreased in the order: II III, I, IV. Addn. of V increased growth on II but caused earlier degeneration and spore formation. Growth was impaired by addn. of V to III or by addn. of V or 0.1% K_2HPO_4 to I and was increased by addn. of 0.1% $(NH_4)_2SO_4$ to I. Growth was good on the undild. aq. ext. of III and was poor on the undild. aq. ext. of I and on exts. of wheat- (VI) and oat-straw (VII) prepd. from 500 g. straw + 2 l. H_2O as above: Addn. of V to the aq. exts. was detrimental. The growth of cultivated mushroom on the artificial media was best on I, poorer on II and IV, very poor on III; addn. of V was disadvantageous in all cases. Growth was good on VI and VII, poor on the undild. aq. exts. of I and III; addn. of V again was detrimental. The growth min. of *M. fimicola* on bean-agar is at pH 4, the optimum at 6.44–7.0, the max. at 8. Optimum temp. is 18–20°. The growth of mushroom is best at pH 6.6–7.0, and poorer at lower and higher values. The effect of temp. varies with the source of the culture. Expts. show that *M. fimicola* can assimilate N only as nitrate, while mushroom can assimilate N as nitrate or amide. Neither utilizes ammonia N. *M. fimicola* growing on bean-agar was treated with various *fungicides*, including 0.1% $HgCl_2$, 1 and 2% Bordeaux and lime-S mixts., the seed disinfectant Ceresan, and formalin. A 2% soln. of formalin was most effective. Difficulties encountered in the use of fungicides are discussed. Edwin J. Seiferle

The root-rot disease of cotton in the Punjab. VI. Chemical composition of healthy and diseased cotton plants. R. Sahai Vasudeva and Mohammad Rafique. *Indian J. Agr. Sci.* **9**, 331–42(1939).—Diseased cotton plants which have wilted as a result of root-rot attack are higher in reducing sugars and sucrose in all parts, i. e., root, stem and leaf, than the corresponding parts of healthy plants. Total N, NH_3, Fe and the Ca:K ratio are higher in diseased than in healthy roots. The ratios of (Fe in leaf):(Fe in root) and (Ca in leaf):(Ca in root) are lower in diseased plants but the ratio (K in leaf):(K in root) is higher in diseased than in healthy plants. J. T. Sullivan

Hot-water treatment [of narcissus bulbs] with the addition of chemical disinfectants. E. R. Wallace. *Agr. Inst. Expil. Sta., Kirton, Rept. Bulb Expts.* **1936**, 38–41.—Treatment of healthy bulbs at 110°F. for 3 hrs. with solns. of either formalin (1:400) or Me Hg phosphate (1:400) had no adverse effect on yields of flowers and bulbs from the subsequent crop. A cold dip of formalin (1:100) for 8 hrs. was very injurious to the bulbs. K. D. J.

The hot water treatment of narcissus bulbs, 1935–36. J. Wood. *Agr. Inst. Expil. Sta., Kirton, Rept. Bulb Expts.* **1936**, 25–37.—Bulbs were severely injured when they were plunged into cold water immediately after they were subjected to the standard hot-water treatment (100°F. for 3 hrs.). Bulbs that were stored at 80°F. prior to the hot-water treatment subsequently produced more flowers than did those stored at 60°F. There seemed to be some advantage in storing bulbs at 80°F. before the hot-water treatment and then storing them at 60°F. after the treatment, as compared to the opposite procedure. K. D. Jacob

Determination of pyrethin I. Linearity of results by the mercury-reduction method. D. A. Holaday and J. J. T. Graham. *Ind. Eng. Chem., Anal. Ed.* **12**, 80–1(1940).—Wilcoxon (*C. A.* **30**, 8076[3]) proposed a method for detg. pyrethin I which was based on the reduction of the $HgSO_4$ in Denigès reagent to the mercurous condition followed by pptn. as Hg_2Cl_2 but found the method limited to detg. 50–70 mg. of the substance. Martin (*C. A.* **33**, 3036) and Holaday (*C. A.* **32**, 3078[7]) showed that the results were not directly proportional to the actual content. H. showed that the errors were caused by the presence of unsatd. org. compds. which titrate with the iodate soln. along with the $HgCl_2$. He proposed a modification which has been adopted by the Assoc. Off. Agr. Chemists. The work here described was undertaken to det. whether this modification gives results linear with respect to the quantity present and such was found to be the case. W. T. H.

Basicop as a cherry spray in 1938. Colin W. Robertson and Donald Cation. *Mich. Agr. Expt. Sta., Quart. Bull.* **21**, 291–5(1939).—Liquid lime-S used at a concn. of 2.5:100 and used 4 times during the season did not give adequate control of cherry leaf spot caused by *Coccomyces hiemalis*. The tendency to dwarf the fruit and to injure foliage renders Bordeaux mixt. 6:8:100 unsatisfactory. Cupro K gave good control of leaf spot but severely injured the foliage. Basicop-lime concns. of 3:8:100 or 3:6:100 gave good control of the disease without significant foliage injury. $ZnSO_4$ may be used in place of the lime to prevent leaf injury. Four sprays are used at proper intervals. C. R. Fellers

Entomological Section. Annual Report. H. Wilkinson. *Rept. Dept. Agr. Kenya 1937*, **2**, 86–101(1939); *Rev. Applied Entomol.* **27A**, 666–7.—Lime-S sprays (1:80) gave complete control of *Thrips tabaci* Lind. on pyrethrum plants. Expts. showed that 5 g. of locally produced pyrethrum powder per tree gave a high percentage kill of *Antestia* on coffee trees. Tobacco powder was only slightly toxic, and a 1:1 mixt. of pyrethrum and tobacco gave variable results. Coffee seed treated with CS_2 or heated to 120°F. for control of *Stephanoderes* [*hampei* Ferr.] showed no differences in germinative capacity attributable to the treatments. Edwin J. Seiferle

Emulsions. N. I. Timokhina. *Trudy Sredneaziat. Sta. Zashchite Rastenii* No. 2, 65–71(1937); *Rev. Applied Entomol.* **27A**, 626–7.—In lab. investigations on the prepn. of stock emulsions, it was found that certain combinations of various distillates of petroleum, Na soap and H_2O pro-

duced H_2O-in-oil emulsions which were not suitable for large-scale use in insecticides. "Instantaneous" emulsions were substituted. The instantaneous stock emulsions tested contained, besides H_2O, 1.3% NaOH, 10–12% acidol (naphthene acids from the alkali residue obtained in refining solar oil and kerosene) and 50–72% mineral oil. Edwin J. Seiferle 1

Relative solubility of the lead arsenates and calcium arsenates. R. P. Tucker. *Bull. Dept. Agr., Calif.* **28**, 276–83(1939).—The possible effect of CO_2 in concns. such as the atm. provides; of sol. chlorides; of hydrolysis; and of the components present as very sol. impurities upon the soly. of the As_2O_5 component of the Pb and Ca arsenates is discussed. Basic Pb arsenate in field practice should be very resistant to the effect of hydrolysis, to CO_2 and to sol. chlorides so far as the soly. of the As_2O_5 is concerned. Lab. studies further showed that dilead arsenate should not be seriously affected by either hydrolysis or by CO_2 but that it is very susceptible to the action of sol. chlorides. Basic Ca arsenate is not seriously affected by hydrolysis nor by sol. chlorides, but it is susceptible to the action of atm. CO_2. The As_2O_5 component, if present in small amts. as a very sol. impurity in the com. materials, may have a decided influence upon the toxicity of basic Pb arsenate, of dilead arsenate and of basic Ca arsenate to foliage. Manufacturers of these arsenicals should exercise the greatest possible care that sol. impurities contg. the As_2O_5 component be kept down to the very min. that industrial practice will allow. C. R. Fellers 2 3

Evaluation of the comparative toxicity of preparations of fluorine and arsenic. T. I. Bezrukova. *Trudy Srednеaziat. Sta. Zashchite Rastenii* No. 2, 72–85(1937); *Rev. Applied Entomol.* **27A**, 627.—Lab. expts. were made in Uzbekistan to det. whether F compds. could be substituted for As compds. in combating phytophagous insects. The poisons were tested by feeding dusted leaves, the rates of application being the same against a given species of insect. Na and Ca arsenites were most effective, but as they scorch plants severely, they can only be used in baits or on weeds. Ca arsenate was next most effective against *Calliptamus italicus* L., but against other insects (larvae and adults of *Hypera* (*Phytonomus*) *variabilis* Hbst., adults of *Rhynchites auratus ferganensis* Nevsk., and larvae of *Agrotis* (*Feltia*) *segetum* Schiff., *Lymantria* (*Porthetria*) *dispar* L., and *Bombyx mori* L.), it was inferior to Paris green, $BaSiF_6$, NaF or Na_2SiF_6. The latter was most effective of the F compds., but Na_3AlF_6 and BaF_2 also gave promising results. Pb arsenate, tested only on *R. auratus ferganensis*, was less effective than NaF, Na_2SiF_6 or $BaSiF_6$, apparently owing to repellence. Edwin J. Seiferle 4 5

Tests on new dust and liquid fungicides in 1938 for control of celery leaf blights. Ray Nelson. *Mich. Agr. Expt. Sta., Quart. Bull.* **21**, 295–307(1939).—Cuprocide-S-talc dusts gave superior control of leaf blights and possessed excellent coverage and flowage properties. Basicop-S-talc and Bordow-S-talc dusts were less satisfactory than Cuprocide but about equal in effectiveness to $CuSO_4$-lime and $CuSO_4$-lime-talc prepns. Bordeaux 8-12-100 and 8-6-100 controlled leaf diseases without perceptible injury to the foliage more effectively than the Cu fungicides of low soly., all of which caused sufficient injury to reduce yields. Grasselli Copper A was an effective fungicide but it caused injury to the foliage. $Ca(OH)_2$ and $ZnSO_4$ failed to prevent injury to the foliage by Basicop sprays. C. R. Fellers 6 7

The production of barium polysulfide. M. Gabrielova. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 10, 38–9(1939).—BaS_x for *insecticides* is prepd. by fusing a 3:1 mixt. of $BaSO_4$ and coke or coal at 1100–1250° for 3–7 hrs., cooling, grinding and mixing in a ball mill with S. H. M. L. 8

Report of the North East of Scotland Sheep Tick Committee—1938, 55 pp. *Appendix* No. 4 (Pub. 1939); *Rev. Applied Entomol.* **27B**, 242–3. **Investigations on tick control.** Walter Moore. In expts. on serial dipping for control of *Ixodes ricinus*, L., on sheep, 100% kill of all stages of the tick was attained by a dip consisting of 1 part *Derris elliptica* root (contg. 5% rotenone) and 500 parts H_2O. Sheep immersed 30 sec. were protected from reinfestation for 9–10 days. A mixt. of mineral oil, wool grease and pyrethrum ext. protected lambs for 30 days, but the smearing was too laborious a process. Expts. are being carried out with a portable power sprayer capable of treating small nos. of sheep on the spot, either in a spray chamber or by hand with power sprayers. Edwin J. Seiferle 9

Compilation of information on kudzu, *Pueraria thunbergiana* [as N fixer] (Miles, Cross) **12**. Complex process for treating Fe ore contg. P and phosphorite [slag used for fertilizer] (Malets) **9**.

MacEwan, J. W. G., and Ewen, A. H.: General Agriculture. Toronto: T. Nelson and Sons, Ltd. 345 pp. Reviewed in *Sci. Agr.* **20**, 254 (1940).

Superphosphate. Leroy H. Facer. Can. 386,798, Feb. 13, 1940. A mixt. of phosphate rock and acid is poured in a box-like enclosure in successive batches each in sufficient depth to increase the temp. and the pressure by confining within its intercellular structure the heat and pressure due to the chemical reaction. The block is left intact and untreated until the curing is complete. An app. is described. Cf. *C. A.* **33**, 1084[7].

Fungicidal and insecticidal material. Wm. P. Ter Horst (to United States Rubber Products, Inc.). U. S. 2,181,217, Nov. 28. Foliage sprays, etc., are used contg. a reaction product of acetonyl acetone and NH_4 thiocyanate (suitably in an aq. suspension).

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Researches on fermentation for the production of gallic acid. III. Effect of adding yeast. Chi-Liang Kuo. *Hwang-Hai* **1**, No. 2, 11–19(1939).—The rate of fermentation of a gallnut ext. increases with its concn. Yeast accelerates this fermentation, since its addn. to the fermentation mixt. causes the fermentation to proceed more rapidly than when bacteria alone are used. Moreover, the yield of gallic acid is also increased. If yeast is added first and then the bacteria are added there is a slightly more rapid fermentation than when both cultures are added simultaneously. **IV. Optimum concentration of gallnut extract and rate of fermentation.** Kwang-Chu Hsieh. *Ibid.* No. 3, 1–3.—The optimum concn. of gallnut ext. for fermentation to gallic acid is 10–13°Bé. With an 11°Bé ext., the fermentation requires 15–20 days and the yield is 70%. Addn. of 2% sucrose has apparently no favorable effect. **V. Changes in tannin content, gallic acid content and total acidity in the fermentation liquor [during the fermentation].** Wen-Teh Wei. *Ibid.* 4–5.—When a gallnut ext. of sp. gr. 1.14 is allowed to ferment at 20°, the gallic acid content increases in 16 days to about 0.09 g./cc. and then remains substantially const. on further standing. When this condition is reached, the decompn. of tannin proceeds more slowly. The total acidity remains substantially const. throughout the process. C. L. Tseng 9

Distilled vinegar. H. J. Fisher. *Conn. Agr. Expt. Sta.* (New Haven), *Bull.* **426**, 21–3(1939); *43rd Rept. Food Products.*—The O_2 value method of Schmidt (*C. A.* **29**, 7574[4]) was used to detect the presence of distd. vinegar (AcOH) in cider vinegar. None was found in the 14 samples examd. C. R. Fellers

Report on the fermentation industries for 1939. Prepared for the Society of Chemical Industry and the In-

stitute of Brewing. Alan A. D. Comrie. *J. Inst. Brewing* **45**, Suppl. 29 pp.(1939).—One hundred and seventy-eight references. Quick Landis

Black-ended barley grains. S. K. Thorpe. *J. Inst. Brewing* **46**, 34–7(1940). Quick Landis

Pentosans and related products in malting and brewing. I. A. Preece. *J. Inst. Brewing* **46**, 38–48(1940).—Malting produces a large increase in furfurogenic substances of which 12–20% appears in the wort. This is further decreased upon fermentation to 8–15%. The probable nature of wort and beer pentosans is discussed. 28 references. Quick Landis

Laboratory malting. III. Steeping equipment and method. J. A. Anderson and W. O. S. Meredith. *Cereal Chem.* **17**, 66–72(1940); cf. *C. A.* **31**, 6405[1].—A nearly automatic laboratory steep tank is illustrated and described. Details of the construction of the tank and of its operation are given. L. H. Bailey

Determination of amino nitrogen in malt extracts. S. R. Snider. *Cereal Chem.* **17**, 121–9(1940).—Practically pure neutral HCHO should be used in preference to a cloudy liquid that sediments on standing. Inferior grades are objectionable as they interfere with the continuity of procedure and the technique of the analyst. The blank for the HCHO is useless unless detd. in the presence of the reagents used in the test. The use of a standard com. set of pH color standards is more convenient than the use of buffer solns. used in conjunction with indicators. The pH of the buffer solns. is subject to change from day to day owing to handling and exposure to CO_2 in the atm. The prepn. of the buffer solns. is time-consuming and tedious. The use of phenol red and thymol blue indicators is preferable to neutral red and phenolphthalein indicators, resp. The amt. of indicator in the test soln. must be equal to the amt. in the color standard. Greater accuracy is possible by the use of a daylight lamp and comparator combination, than by daylight. The modified method, simplifying Pawlowski's method, is convenient, consistent, and adaptable to routine purposes. L. H. Bailey

---

Production of active AmOH from fusel oil (Birun) 10.

Hwang-Hai (Yellow Sea) (*New journal*). Deals with fermentation and bacteriology. Published bimonthly by the Golden Sea Research Institute of Chemistry. Wu-Tung-Chiao, Szechuan, China. Vol. 1, No. 1 appeared in June, 1939. Mex. $1.00 per yr. (domestic).

Baeta Neves, Luiz M.: Technologia da fabricacao do alcool. S. Paulo: Editado pela "Revista brasileira de chimica." 314 pp.

Fermentation process for the production of alcohol, etc. Leo M. Christensen (to Chemical Foundation, Inc.). U. S. 2,182,550, Dec. 5. An arrangement of app. is described, and a method of producing alc. and other products from amylaceous starting material which comprises fermenting a saccharified amylaceous mash in a fermenter with *Saccharomyces cerevisiae* to produce EtOH; the products of fermentation are distd. in a distn. zone to recover a concd. aq. alc.; the residue from the distn. zone is passed to a second fermenter and there is added to the residue in such fermenter an amylaceous mash. The material in the second fermenter is inoculated with *Clostridium acetobutylicum* to produce EtOH, BuOH and acetone. The products of conversion from the second fermenter, together with the products of conversion from the first fermenter, are passed to the distn. zone for co-distn. therein and the distd. vapors are fractionated to recover a concd. aq. EtOH substantially free from higher alcs. and acetone. The concd. aq. EtOH is then subjected to dehydration to produce anhyd. alc.

Butyric acid production by fermentation. Rafael Arroyo (to Borinquen Associates, Inc.). U. S. 2,181,310, Nov. 28. A process of prepg. butyric acid includes the steps of prepg. a mash from molasses and having a sugar concn. of about 4.6–8.5% and a pH of substantially 6.8 to 7.0, inoculating with *Clostridium saccharobutyricum* and fermenting by the action thereof at a temp. of about 30–32° in the continued presence of an excess of $CaCO_3$ over that required for neutralization of the butyric acid, and sepg. a butyric acid compd. from the spent mash. U. S. 2,181,311 relates to a butyric acid fermentation mash of *Clostridium saccharobutyricum* and an aq. substrate having a concn. of about 6.5% by way of sucrose and invert sugars.

Centrifugal rectification and distillation of materials such as alcohol. Juan Loumiet et Lavigne. U. S. 2,182,566, Dec. 5. See Brit. 507,435 (*C. A.* **34**, 291[4]).

Fermentative production of solvents from garbage. James W. Jean. U. S. 2,182,989, Dec. 12. A process of manufg. BuOH, acetone and EtOH from garbage waste involves reducing the waste to a mash, admixing a fermentable mash prepd. from grains, cooking for about 2 hrs. and adding water to produce substantially a 5% carbohydrate mass, adding about 10% of a culture of *Clostridium felsinae* and fermenting at a temp. not substantially above 37°.

Wine. Donald K. Tressler (to Cornell Research Foundation). U. S. 2,181,838, Nov. 28. An arrangement of app. is described, and a wine-making process which consists in taking wine stock including wine made from grapes of Labrusca blood, having a bright red color and foxy flavor, heating it substantially above room temp. but below 65°, simultaneously passing through the heated stock large quantities of minute bubbles contg. O, and regulating the combined effect of time and temp. so that the O treatment is terminated before the stock develops a sherry flavor, whereby the foxiness is eliminated and the color changed from red to tawny. U. S. 2,181,839 relates to a process for making sherry wine, which consists in taking wine stock including wine made from grapes of Labrusca blood, heating it to about 57°, and maintaining it at that temp. for several weeks, and simultaneously passing large quantities of minute bubbles contg. O through the heated stock, whereby a sherry flavor is produced in a few weeks.

Extracting the essential principles of hops. Lyndon D. Wood (to National Hops Laboratories, Inc.). U. S. 2,181,931, Dec. 5. A process is employed which involves finely pulverizing and crushing the entire mass of hops, simultaneously liberating the hop-seed oil content of the seeds and the hop oil from the hop-blossom leaves, and commingling the hop oil with the hop-seed oil to retard or stop evapn. of the hop oil and aroma, recovering a large percentage of hop oil, and subjecting the pulverized hops to the action of acetone in a closed chamber.

Apparatus for cleansing pipes by use of soda solutions, etc. Fred Buchhorn. U. S. 2,183,007, Dec. 12. Various structural and operative details of app. adapted for cleansing pipes such as those used for beer.

17—PHARMACEUTICALS, COSMETICS AND PERFUMES

W. O. EMERY

Determination of the apparent specific volume of official powders and its analytical and technical utility. Romolo Mazzucco. *Boll. chim. farm.* **78**, 517–19(1939). —On many occasions the apparent sp. vol. of a powder or pulverized drug is a magnitude of some importance. This is simply detd. by introducing 25 g. of powder into a 50 cc. or 100 cc. graduated cylinder, allowing the cylinder to drop about 5 cm. onto the palm of the hand 10 times (slight compression) and rapping 50 times on a hard surface (medium compression), reading the level and dividing by 25. A tabulation of the apparent sp. vol. of some 30 slightly and medium compressed powders is given. C. R. Addinall

Essential oils from the Queensland flora. XVII.

Evodia littoralis and the occurrence of a new phenolic ketone. F. N. Lahey and T. G. H. Jones. *Univ. Queensland Papers, Dept. Chem.* 1, No. 13, 4 pp.(1939).—Steam-distn. of 180 lb. of leaves from *Evodia littoralis* gave 182 cc. of oil, $d_{15.5}$ 0.8487, $[\alpha]_D$ +16.5, n^{20}_D 1.4860, ester value 0, Ac value 36. Extn. of the oil with NaOH soln. yielded 9 g. of a phenol, *evodionol* (I), $C_{13}H_{18}O_4$, yellow crystals from petr. ether, m. 84°; the *Me* (II) and *Ac derivs.* of I are white solids, m. 78° and 66°, resp. Treatment of I with alc. $FeCl_3$ gives a green color which turns red upon addn. of $NaHCO_3$. The *2,4-dinitrophenylhydrazones* of I and II are amorphous and red, resp., and m. 217 and 157°, resp. The residual oil yielded the following fractions on distn. at 2 mm., the b. p., $d_{15.5}$, $[\alpha]_D$ and n^{20}_D being, resp.: (III), 32–3°, 0.8555, +41.7, 1.4662; (IV), 36.5–7°, 0.8039, +3, 1.4822; (V), 60–70°, 0.9232, +7, —; (VI), 82–5°, 0.9100, −2, 1.4950; (VII), 92–5°, 0.9286, +17, 1.4982; (VIII), 108–12°, 0.9765, −5, 1.4970. After removal of ocimene from III by $(:CHCO)_2O$, the remaining oil was identified as *d*-α-pinene. V contained a sesquiterpene and an alc. resembling linaloöl. VI and VII consisted of sesquiterpenes which yielded a small amt. of azulene but neither cadalene, nor eudalene on treatment with Se at 280°. VIII probably contained the same sesquiterpene as VII. David E. Adelson

Some varieties of Ephedra from Sardinia. Maria Mulas and Edina Salis. *Arch. ist. biochim. ital.* 11, 315–34(1939).—*E. vulgaris* from Sardinia contained from 0.75 to 1.83% of *d*-pseudoephedrine; *E. nebrodensis* contained 3.4%. E. S. G. Barron

A new method of detection of pharmaceutical substances: carotenoids, glycosides, alkaloids, vitamins, by chromatographic analysis. Elsior Coutinho. *Pub. farm.* (São Paulo) 5, 5–11(1939).—A review. E. S. G. B.

Determination of the adsorptive power of medicinal charcoal. C. H. Liberalli and Olavo Fontoura. *Rev. quím. farm.* (Rio de Janeiro) 4, 101–6(1939).—A discussion of the methods used by the Brazilian Pharm. Detn. of the adsorptive power of medicinal charcoal with methylene blue, strychnine sulfate and H_2S is recommended. E. S. G. Barron

Preserving properties of essential oils and synthetic odoriferous substances used in cosmetics. E. Shevlyagina and R. Rutkovskaya. *Maslobo˘no Zhirovoe Delo* 15, No. 4, 31–2(1939).—Comparative tests showed that the addns. of common natural and synthetic aromatic substances to cosmetic creams retard or inhibit the growth of molds. A complete inhibition of molding was effected on the addn. of these aromatic substances to beer wort infected with cultures of *Aspergillus glaucus* and *Penicillium glaucum*. Several tables are given, showing the comparative effectiveness of various essential oils and synthetic aromatics in the suppression of mold growths in emulsified creams and beer wort. Chas. Blanc

Determination of odoriferous substances in alcohol-water solutions. M. Elderman. *Maslobo˘no Zhirovoe Delo* 15, No. 4, 33(1939).—A polemic with A. I. Naĭmark and N. A. Suvorova, *C. A.* 33, 807[5]. Chas. Blanc

A comparative study of liquor carmini and liquor cocci. Elmer H. Wirth, Frank T. Maker and Victor Lindblade. *Bull. Natl. Formulary Comm.* 8, 10–15(1939).—Color, formulas and names for these solns. have been postulated in accordance with the Munsell system. The behavior of each to various concns. of acid and base is studied. Chem. standard matching solns. are prepd. and a method of colorimetric standardization of the solns. is developed. The color qualities of liquor cocci tend toward a purple; in intensity the color of liquor carmini is 6 times stronger. On the basis of results the authors see no valid reason for deleting either of the solns. from the National Formulary. H. M. Burlage

Foot preparations. M. A. Lesser. *Drug Cosmetic Ind.* 46, 165–7, 171(1940).—The foot ailment, *epidermiphytosis*, and its treatment are discussed. Eleven formulas are offered. 13 references. H. M. Burlage

Cosmetic manual. Liquid creams. Joseph Kalish. *Drug Cosmetic Ind.* 46, 168–9(1940).—These creams include cleansing, skin, hand and foundation lotions and they may be applied easily and uniformly over a large skin area. An outline of their formulation including 33 formulas is offered. H. M. Burlage

Improved assay for areca. *Repts. Am. Pharm. Assoc. Lab., Bull. Natl. Formulary Comm.* 8, 6–8(1939).—The following method based on the German and Swiss pharmacopoeial procedures is recommended: Place 8 g. of areca in moderately coarse powder and accurately weigh into a suitable flask, add 80 cc. of Et_2O, shake well, add 4 cc. ammonia test soln., and shake (preferably in a mech. shaker) during 10 min. Allow to settle and decant the ethereal soln. into another flask. Add 0.5 g. talc to the decanted Et_2O soln. and shake for 3 min., then add 2.5 cc. H_2O and shake for 3 min. more. Let stand until clear, decant 50 cc. of the ethereal soln. equiv. to 5 g. of areca and distil off about ⅔ of the Et_2O. Ext. the remaining Et_2O in a separatory funnel, with 15 cc. 0.02 *N* H_2SO_4 and then with 3 portions of H_2O, using 5 cc. each time. To the combined acid soln. and washings, add methyl red test soln. and titrate the excess acid with 0.02 *N* NaOH. Each cc. 0.02 *N* acid is equiv. to 0.0031 g. arecoline. H. M. Burlage

Oil of rose geranium. *Repts. Am. Pharm. Assoc. Lab., Bull. Natl. Formulary Comm.* 8, 30–2(1939).—Three types of oil (7 samples of Bourbon, 4 of Algerian, and 3 French) were studied. Color, sp. gr., $(\alpha)_D$, and ester no. are reported. The oils differ only in sp. gr. and odor. H. M. Burlage

Sodium glycerophosphate. The free phosphate test. *Repts. Am. Pharm. Assoc. Lab., Bull. Natl. Formulary Comm.* 8, 38–40(1939).—A turbidimetric test for free phosphate ion in Na, Ca, Fe and Mn glycerophosphates is described. H. M. Burlage

Volatile oil content of Salvia. *Repts. Am. Pharm. Assoc. Lab., Bull. Natl. Formulary Comm.* 8, 93–6(1939).—By use of Clevenger's method (cf. *C. A.* 33, 8918[3]) 3 samples of official sage were found to yield 1.2, 1.1 and 1.3% volatile oil and the following consts. were reported: d_{25} 0.918, 0.925, 0.925; optical rotation (25°, 100 mm. tube) 9.2, 6.7, 7.5; n_{20} 1.4616, 1.4645, 1.4640; acid no. 1.8, 2.0, 1.8; ester no. 4.9, 6.8, 4.5. Fifteen references. H. M. Burlage

The acid numbers of the official tinctures of the Pharm. Hung. IV. II. István Novák. *Magyar Gyógyszerésztud. Társaság Értesítője* 16, 11–15(1940); cf. *C. A.* 33, 7486[1].—On storage for 12 months, the acid nos. generally decreased, probably owing to the soln. of alkalies from the green-glass containers. The numerical results are tabulated. S. S. de Finály

The ash contents of the official drugs of the Pharm. Hung. IV. Károly Kodrik. *Magyar Gyógyszerésztud. Társaság Értesítője* 16, 16–51(1940).—The ash was detd. in 10-cc. quartz crucibles by ignition of 0.5 g. powd. drug over a Barthal lamp heated by alc. The following values are recommended as max. percentage total and acid-insol. ash contents. Bitter-orange peel 6, 0.5; cinchona 4, 1; cassia bark 5, 1; condurango 12, 1; frangula 7, 0.5; pomegranate bark 16.5, 2.5; althaea leaves 17, 3; belladonna leaf 16.5, 3; digitalis 12, 3; hyoscyamus 24, 8; mallow leaves 17, 3.5; peppermint 12, 1.5; salvia 12, 1; senna 12, 2–3; stramonium 21, 5; trifolium 10.5, 2; uva ursi 4, 0.5; althaea root 7, 0.5; angelica root 12, 4; gentian 5, 1; hydrastis 3, —; ipecac 5.5, 2.5; jalap 6.5, 1.5; glycyrrhiza 6.5, 1.5; ononis 7, 2.5; krameria 4.5, 1; *Saponaria hungarica* root 9, 1; senega 5, 2; taraxacum 9, 3; valerian 13, 6.5; calamus 6, 1; aspidium 4, 1; triticum 5, 2.5; orris 4, 0.5; rhubarb 14, 1; zedoaria 7, 2; ginger 7, 2; salep 3.5, 1. The values prescribed by the pharmacopeias of various countries are compared. S. S. de Finály

A new type of percolator "Nera" with a dropping tap. Imre Némedy and János Ragettli. *Magyar Gyógyszerésztud. Társaság Értesítője* 16, 52–5(1940).—The dropping tap has an opening of continuously decreasing size. It gives drops as prescribed by the pharmacopeias at a rate that can be kept const. for 4 days. The structure of the tap is shown by figures. S. S. de Finály

The determination of aneurin (vitamin B_1) in drug preparations. Gábor Vastagh. *Magyar Gyógyszerésztud. Társaság Értesítője* **16**, 56–68(1940).—A modification of the methods of Jansen (*C. A.* **31**, 1443[8]) and Karrer and Kubli (*C. A.* **31**, 6275[8]) is described. Best results were obtained if the sample contained about 5 γ of aneurin hydrochloride in 10 cc. water. To 150 cc. soln. in a separatory funnel add 5 cc. of 1% $K_3Fe(CN)_6$ soln., mix, add 10 cc. 10% NaOH soln., shake, and let stand for 2 min. Add 20 cc. isobutyl alc., shake for 1 min., filter through fat-free cotton into a 25-cc. measuring flask. Repeat the extn. with 5–6 cc. isobutyl alc. and fill the flask to the mark with the filtrate. If the soln. opalesces (an indication of water in the isobutyl alc.) add 1 g. anhyd. Na_2SO_4, let stand overnight and filter. Measure the fluorescence of the thiochrome soln. by means of a Hanau analyzing lamp and a Pulfrich step photometer, and compare with that of a standard soln. prepd. from cryst. aneurin hydrochloride. If the sample contains other fluorescing substances, aneurin is adsorbed by fuller's earth preps. The method gave results with errors of not more than plus 8 or minus 16%. S. S. de Finály

Isolation of α-amyrin and ursolic acid from yerba maté. Jorge R. Mendive. *Rev. inst. bacteriol. dept. nacl. hig.* (Buenos Aires) **9**, 190–6(1939).—Dried yerba maté yielded over 0.43% of α-amyrin, m. 183 5°, and a very small amt. of ursolic acid, m. 285°. The substance found by Hauschild in 1935 (cf. *C. A.* **30**, 3537[7]) and named matesterol by him is ursolic acid. L. E. Gilson

Isolation of aspidospermine from Vallesia glabra (family Apocynaceae). V. Deulofeu, J. de Langhe and R. Labriola. *Rev. inst. bacteriol. dept. nacl. hig.* (Buenos Aires) **9**, 224–6(1939).—Dried leaves yielded about 4% and stems 2%. The amt. in the roots is small and uncertain. L. E. Gilson

Identification of exalgine (methylacetanilide) and its detection in antineuralgic mixtures. A. Denoël. *J. pharm. Belg.* **21**, 691 5, 709–11(1939).—Exalgine can be identified by its pptn. reactions with $K_4Fe(CN)_6$ in acid medium, $AuCl_3$ I in AcOH and KIO_3 in strong HCl soln. *Detection in exalgine-antipyrine mixt.* Remove the antipyrine by pptn. with Lugol's soln. or with 40% NH_4SCN in slightly acid medium and ext. the exalgine from the filtrate with ether. *Exalgine-antipyrine-pyramidone mixt.* Remove the antipyrine and pyramidone by pptn. with Lugol's soln. and ext. the exalgine from the filtrate with ether. S. W. Goldstein

Isolation and purification of the active principles of Acocanthera abyssinica. G. Menta. *Ateneo parmense* **11**, 169 75(1939).—A pure active glucoside fraction was isolated by the method of Braga (cf. *C. A.* **28**, 5595[9]). Helen Lee Gruehl

Glycol as an injectable solvent in pharmaceutical practice. Antonio Mossini. *Ateneo parmense* **11**, 242–6 (1939).— Glycol was shown to be efficacious as an injectable solvent especially in the case of camphor and folliculin. The necessity of previously testing the behavior of such solns. was stressed. Helen Lee Gruehl

Preparation of an injectable solution of quinine iodobismuthate. Antonio Mossini. *Ateneo parmense* **11**, 386–8(1939).—Ten g. quinine iodobismuthate were dissolved in a mixt. of 290 cc. ethylene glycol and 10 cc. 50% KI soln. The resulting soln. was not very viscous, could be sterilized below 60° and was easily injectable. Helen Lee Gruehl

Estimation of traces of lead and thallium in pharmaceutical chemicals. A simple dithizone limit test. Karl Bambach. *Ind. Eng. Chem., Anal. Ed.* **12**, 63–6(1940). —The dithizone test described here is simple, rapid and sensitive. It is much better than the "heavy-metals test" prescribed in the U. S. Pharmacopoeia which does not distinguish between toxic and relatively nontoxic metals. Dissolve a little of the sample in 6 *N* HNO_3, boil and cool. Transfer the soln. to a graduated sepg. funnel and add suitable quantities of NH_4 citrate, KCN and $NH_2OH.HCl$. Make the soln. basic to phenol red with freshly distd. NH_4OH and then shake with 5 ml. of dithizone soln. contg. 12 mg. of the reagent per l. of $CHCl_3$. Ext. the soln. with repeated portions of the reagent until finally the latter retains its green color. Shake the combined $CHCl_3$ exts. with 20 ml. of 1% HNO_3 and discard the $CHCl_3$ layer. Treat an aliquot part with NH_4OH and KCN as before and compare the color of the resulting dithizone ext. with standards. The test was applied to over 50 substances and in a few cases, particularly when Bi was present, a modification of the procedure was necessary. W. T. H.

Qualitative test for ethylvanillin in vanilla extract. Howard W. Chenoweth. *Ind. Eng. Chem., Anal. Ed.* **12**, 98 9(1940).—The undeclared addn. of ethylvanillin to pure vanilla exts. constitutes an adulteration which is not easily detected. The method here described will serve to detect 0.5 g. of the ethyl compd. in 3.78 l. of vanilla ext. Take a 50-ml. portion of the ext., remove the alc. by evapn., treat with $Pb(OAc)_2$ and ext. with ether by the standard method of the A. O. A. C. Place the ether ext. in a beaker and allow the ether to evap. overnight in a desiccator. Add to the residue 1 ml. of 8 *N* HCl and heat at 55° until all is dissolved. Transfer to a test tube without washing, add 1 ml. of 3% H_2O_2 and shake frequently while the color is changing to yellow, brown and then red with the final formation of a blue ppt. Allow to stand 15 min., add 15 ml. of benzene and keep at 55° with frequent shaking until the lower aq. layer becomes a dirty yellowish brown. Carefully pour off, or pipet off, most of the benzene layer into a dry test tube. If the benzene is colored violet, ethylvanillin is present; otherwise the benzene is colored a light or dirty yellow. W. T. H.

Titration of euquinine and aristochin. N. Schoorl. *Pharm. Weekblad* **76**, 1513 16(1939).—Euquinine was found to have dissocn. consts. $pK_1 = 7.15$, $pK_2 = 10.5$ (quinine has 6.0 and 9.7). On the basis of these values a titration method for euquinine is as follows: Dissolve 198 mg. (0.5 millimole) euquinine in 10 cc. 0.1 *N* HCl in the cold. Dil. the soln. with 200 cc. neutral water and 5 drops of neutralized methyl red indicator soln. In another flask place 10 cc. acetate buffer soln. (normal) of pH 5.2, dil. with 200 cc. water and add indicator. Titrate the euquinine soln. with 0.1 *N* NaOH with shaking until the color of the buffer soln. is obtained. Theory requires 5.0 cc. 0.1 *N* alkali. For aristochin dissolved with 3 mols. of HCl the pK_2 is 9.3; the pK_1 value could not be detd. even in 0.001 *N* soln. without turbidity. Direct titration of aristochin hence is impractical and the detn. is made by heating the substance with HCl to decompose the carbonic acid ester and titrating back the quinine formed. B. J. C. van der Hoeven

Fermentation of Roumanian tobaccos. I. Nitrogenous substances. I. Zaporojanu. *Bul. cultivării fermentării Tutunului* **28**, 379–453(in French, 454–62)(1939).— Expts. on the N metabolism of 18 Roumanian tobacco varieties show that the albuminoid substances in general undergo no abs. quant. modification in the course of fermentation. Nitrogenous substances undergo changes in such of their constituents as are sol. in boiling H_2O; this is shown by the accumulation of NH_3 originating in the amino acids and amides. The decompn. of nicotine is very much reduced, owing probably to the previous processes of searing and drying and to the feeble activity of the sp. oxidizing enzymes. Migrations of sol. N from the margin to the center nerve were observed, especially for nicotine. The dry substance is generally enriched in all forms of N, but, with the exception of NH_3 and albuminoid substances, these increases are too small to be of practical importance. A. H. Krappe

A photoreducing substance contained in commercial candiolin. Motomasa Tawara. *J. Biochem.* (Japan) **30**, 459–64(1939).—Candiolin (Na hexosediphosphate) contains a substance which, under the influence of light, exerts a strong reducing action on methylene blue. This effect is not assocd. with any catalytically active substance, nor was any evidence obtained that ascorbic acid was present in the candiolin. Hexosediphosphoric acid itself does not manifest this property. The substance in ques-

tion bears a close resemblance to Euler's reductone, which is thought to be an impurity in the com. prepn. S. Morgulis

Trilaurin as a substitute for coconut oil for pharmaceutical preparations. Tatuo Kariyone and Saburo Mizutani. *J. Pharm. Soc. Japan* **59**, 570-1(1939).—Trilaurin is prepd. commercially from laurin and glycerol and is a mixt. of α-monolaurin (m. 59°), β-monolaurin (m. 60.5°), α,α'-dilaurin (m. 55°) and trilaurin (m. 46°). The prepn. m. 29–38°. F. I. Nakamura

Application of capillary luminescence in pharmaceutical analysis. Hanziro Ito. *J. Pharm. Soc. Japan* **59**, 742–55(1939).—A theoretical and practical consideration. F. I. Nakamura

Officinal cinnamon bark, oil of cinnamon, and their preparations in filtered ultraviolet light. K. Leupin and J. Steiner. *Mitt. Lebensm. Hyg.* **30**, 217–19(1939).—The 2 cinnamon barks, cortex cinnamomi cassiae (I) and cortex cinnamomi ceylanici (II) show no differences under a fluorescent microscope. If, however, their powders are treated with 2 to 3 drops of 10% $Ba(OH)_2$, differences in fluorescence appear which make identification easy. As low as 10% of I in II can be detected. The oil of II (III) in Me_2CO shows no fluorescence, while the oil of I (IV) in Me_2CO fluoresces blue-green. By setting up proper standards it is possible to detect 1% of IV in III. W. J. Peterson

Ethyl chloride. Horace M. Miller. *Bull. Am. Assoc. Nurse Anesthetists* **8**, 18–22(1940). A discussion of the chem. and physiol. properties of EtCl and its anesthetic use in extg. teeth in children. J. Pinchack

Pectin. Raphael M. Nacca. *Druggists' Circ.* **84**, 22–3, 72(Feb., 1940).—Two pectin pastes have been tentatively accepted for inclusion in the National Formulary VII. These are Dense Pectin Paste composed of 2 g. benzoic acid, 150 g. No. 100 grade citrus pectin, 185 g. glycerol and soln. of physiol. salts to make 1000 g., and Thin Pectin Paste which differs from the former in having 60 g. pectin and 75 g. of glycerol in it. Both pastes deteriorate after a few months, even when stored in closed containers. The soln of physiol. salts called for in these pastes will also become official under the title liquor physiologicalis salinis. It is a modification of Ringer's soln. and consists of 8.6 g. NaCl, 0.3 g. KCl, 0.33 g. $CaCl_2$ and distd. water to make 1000 cc. J. Pinchack

Tobacco investigations. III. Successively precipitating aqueous extracts of tobacco with uranyl sulfate and copper acetate. Adolf Wenusch. *Z. Untersuch. Lebensm.* **78**, 407–14(1939); cf. *C. A.* **34**, 1130⁹.—With tobaccos there are 5 important conditions which affect quality: (1) genotype of plant, (2) phenotype of plant, (3) vitality at the time of harvest, (4) type of drying and (5) treatment of the dried tobacco (ripening, fermentation, etc.). Water-poor soil yields low chlorophyll and protein content, as well as quick loss of vitality. N-rich soil increases the nicotine content; this also depends on conditions No. 1 and 2. Effect of time of harvest and drying were discussed in the previous reports. Uranyl value (*A*) and $Cu(OAc)_2$ value (*B*) were detd. as follows: Treat 2 g. of dry finely powd. tobacco with 100 cc. distd. H_2O and allow to stand 4 hrs. at room temp. Filter, wash with 50 cc. distd. H_2O, add 15 cc. of a 10% aq. soln. of uranyl sulfate, filter, dry the ppt. in a desiccator and weigh. Treat the filtrate with 20 cc. of cold satd. $Cu(OAc)_2$, let stand 12 hrs., filter, dry in a drying oven and weigh. The weights of each of the above ppts. are designated, resp., as *A* and *B*. Tobaccos of the acid group give small *A* and high *B*. The more the loss of vitality of dried tobaccos, the lower is the *A*. The reverse is true of the *B*. Bright Virginia tobacco had an *A* equiv. to that of the acid group, while the *B* is higher than any of those of the acid group. This is due to a vital harvest and a type of drying which preserves the Cu-precipitable bodies. To obtain a typical tobacco of the alkali group, i. e., one that yields alkali-reacting N compds. in the smoke, the leaves must be vital harvested to contain a large amt. of protein, dried slowly to remove materials (sugar) giving acid smoke and they must be suitably fermented. Chemical investigations to det. these conditions of tobacco products should be most important for the hygiene of smoking. **IV. Determining the protein in tobacco.** *Ibid.* 477–80.—Results of W.'s investigations are discussed. The results of the tests yield an insight to the harvest, treatment and hygienic effect of the tobacco on the smoker. M. M. Piskur

Fungicidal testing: A comparison of methods. Adelia McCrea. *J. Lab. Clin. Med.* **25**, 538–41(1940).—The method of the author (*Ibid.* **17**, 72(1931)) with slight modifications that have been introduced later is described and its advantages are discussed. Comments are made on the methods advocated by Reddish, by Klarmann and by Taft (*Drug Trade News* **13**, 27(1938)). H. W. R.

Datura arborea (floripondio). Fernando Montesinos A. *Bol. soc. quím. Peru* **5**, 99–123(1939).—In the Solanaceae, there are 3 species of the genus *Datura* which are at present studied in Peru, namely, *D. tatula*, *D. sanguinea* and *D. arborea*. *D. arborea* is an atropine plant, 3 varieties of which exist in Peru. It has the same active principles as belladonna, hyoscyamus and stramonium, namely, the daturine alkaloids, atropine, duboisine and scopolamine. The action of daturine is shown to be superior to that produced by an equal quantity of atropine. Roots and leaves contain the most alkaloids. Galenical prepns. can be prepd. which can be used to replace prepns. of other atropine plants whenever an action of a parasympathetic nature is required. Since the alkaloidal content of *D. arborea* is less than belladonna and almost equal or less than stramonium and hyoscyamus, proportionately larger doses can be employed. Lewis Rosenstein

Coconut oil soap solutions. Charles Spain. *Chem. Products* **3**, 31–2(1940).—The Brit. Pharm. Codex soln. of coconut oil soap becomes cloudy; filtration yields only temporary clarity, and this at the expense of the soap content. The difficulty is due to the use of NaOH in the Codex formula. The following formula gives a soln. that remains sufficiently clear to filter bright, without undue loss of soap: Coconut oil 5 lb., KOH 1 lb., oil of lavender q. s., distd. water to 18 pints. Melt the oil, add 35 oz. of KOH soln. (contg. 1 lb. KOH), mix thoroughly, keep warm for a week, add the rest of the distd. water, dissolve by heating without boiling and place the warm soln. in separators. When the sepn. is completed 24 hrs. later, draw off the clear soap soln., filter through white filter paper, add the preservative and bottle the soln. for storage. Leopold Scheflan

The absorption of cosmetic materials by the skin. Ernst Ohlsson. *Progressive Perfumery & Cosmetics* **1939**, 122–3.—Suitable for use in cosmetics that are not to be absorbed are petrolatum, mineral oils, some waxes and gums, kaolin, talcum, etc. In a cosmetic intended to be absorbed by the skin the ingredients should be similar in nature to those present in the skin and have a m. p. not much higher than body temp. Examples are animal and vegetable oils, lecithin, cholesterol and their derivs. Leopold Scheflan

Body deodorants. I. R. Hollenberg. *Progressive Perfumery & Cosmetics* **1939**, 155–6, 162–3. The formulating of a body deodorant is discussed. L. Scheflan

Coal-tar and natural dyes [for use in drugs and cosmetics]. J. W. Orelup. *Progressive Perfumery & Cosmetics* **1939**, 177–81.—Dyes permitted by the Federal Food, Drug and Cosmetic Act are discussed. The chem. structures of indigo, Tyrian purple, henna (2-hydroxy-1,4-naphthoquinone), cochineal, Indian yellow (euxanthone), dyes derived from flowers, etc., are discussed and the significance of their similarity to those of the coal-tar dyes is pointed out. Leopold Scheflan

Musk. I. The natural product. Ernst Ohlsson. *Progressive Perfumery & Cosmetics* **1939**, 182–4.—A discussion of early history, the place of musk in medicine, the occurrence of musk in animals and plants and its production from natural sources. Leopold Scheflan

Iron hematoxylins containing ferric and ferrous iron. R. D. Lillie and W. R. Earle. *Am. J. Path.* **15**, 765–70 (1939).—**The stability of Fe alum hematoxylin solns. may**

be greatly increased by the addn. of $Fe(NH_4)_2(SO_4)_2.6H_2O$ and especially of $FeSO_4.7H_2O$. F. B. Seibert

Distribution of chem. substances in tobacco (Vladescu, Dimofte) 11D. Dissocn. constants and titration exponents of alkaloids (Schoorl) 2. Effect of substitutents on germicidal activity of phenols (Chien, Yin) 10. Derivs. of phenol obtained from cashew-nutshell oil [as fixatives for perfumes] (U. S. pat. 2,181,119) 10. Benzenecarboxylic acid fluorides contg. trifluoromethyl groups [as intermediates in making pharmaceutical compds.] (U. S. pat. 2,181,554) 10.

Sivadjian, J.: La chimie des produits pharmaceutiques. Paris: Gauthier-Villars et Cie. 163 pp. Fr. 40.

Medicinal compositions suitable for application to the nasal mucous membrane. Gordon A. Alles. U. S. 3 2,181,845, Nov. 28. A medicinal compn. for stimulating peripheral neuromuscular mechanisms under control of the sympathetic nervous system comprises a stable, nontoxic, sol., acid addn. salt of 1-(parahydroxyphenyl)-2-aminopropane such as the hydrobromide together with an excipient.

Carbocyclic alcohol esters of *N*-alkylpiperidinecarboxylic acids. Otto Dalmer and Claus Diehl (to Merck & Co. Inc.). U. S. 2,182,791, Dec. 12. Esters are prepd. 4 which are nonirritating to delicate mucous membranes and which inhibit the development of staphylococci, coli and gonococci. The *N*-methyl-3-piperidinecarboxylic acid thymol ester is especially effective. It b_5 177–8° and its hydrobromide m. about 168°. Its methosulfate m. about 127°. The chloro-*m*-cresol ester b_5 174–6° and its hydrochloride m. about 120°. The eugenol ester b_4 about 174–5°. The 2-carbomethoxyphenyl ester forms 5 a hydrochloride m. about 104–5°. The menthol ester of *N*-methyl-3-piperidinecarboxylic acid b_6 about 165–6° and is a slightly yellow oil. Its hydrobromide m. about 185°. *N*-Methyl-3-piperidinecarboxylic acid menthol ester methosulfate m. 110–12° and by hydration yields *N*-methyl-3-piperidinecarboxylic acid menthol ester methosulfate. *N*-Methyl-2-piperidinecarboxylic acid borneol ester is a light oil b_5 161–2° and forms a cryst. hydrochloride. *N*-Methyl-3-piperidinecarboxylic acid 6 Ph ester is a thick oil and its hydrochloride m. about 60–5°. The 4-phenoxyphenyl ester forms a hydrochloride which m. 167°. The decahydro-2-naphthyl ester b_5 about 183–5° and its hydrochloride m. about 120°. The tetrahydro-2-naphthyl ester b_5 199–200° and its hydrochloride m. about 197°. *N*-Ethyl-2-pyridinecarboxylic acid thymol ester ethylsulfate m. about 130°. *N*-Ethyl-2-pyridinecarboxylic acid thymol ester b_{10} about 186 7°. 7 4-Pyridinecarboxylic acid thymol ester b_5 178–9°. *N*-Methyl-4-pyridinecarboxylic acid methosulfate m. about 166°. *N*-Methyl-4-piperidinecarboxylic acid thymol ester is a slightly colored oil and its hydrochloride m. about 198°. U. S. 2,182,792 relates to compds. such as the thymol ester of *N*-methyl-3-piperidinecarboxylic acid and the corresponding chloro-*m*-cresol and eugenol esters, b_5 and b_4 about 175°.

Thiobarbituric acids. Arthur W. Dox (to Parke Davis 8 & Co.). U. S. 2,182,518, Dec. 5. Therapeutic compds. are produced, of the general formula $PhRC.CO.NH.CS.NM.CO$, where R is an alkyl radical having not more than 7 C atoms and M is H or a salt-forming basic group capable of replacing the H of the imino group, or metal such as K, Na, Rb, Cs or an alk. earth metal or Mg or NH_4 or the radical of an amine. Details are given of the 9 production of ethylphenylthiobarbituric acid, m. 218°, and general mention is made of the production of allyl-, propyl-, isopropyl-, butyl-, amyl- and isoamyl-phenylthiobarbituric acids and their salts. Cf. *C. A.* **33**, 5599[2].

3-Ketopolyhydrocyclopentanophenanthrenes. Max Hartmann and Albert Wettstein (to Soc. pour l'ind. chim. à Bâle). U. S. 2,182,920, Dec. 12. *Therapeutic compds.* forming freely water-sol. salts are produced by treating a hydroxy ketone such as $\Delta^{4,5}$-androsten-17-ol-3-one or the like with esterifying reagents such as succinic anhydride, maleic anhydride, phthalic anhydride, chlorosulfonic acid or P oxychloride. The succinic ester of the $\Delta^{4,5}$-compd. has dimorphous forms which m., resp., 182–4° and 191–3°. Abs. pyridine, quinoline or a dialkylaniline may be used (although not necessary) as a condensing agent in the esterification reaction. Cf. *C. A.* **33**, 3812[1].

Diaminoarsenobenzenemonosulfoxylate derivatives. Frieda Streitwolf (nee Weiss), Administratrix of the Estate of Karl Streitwolf, deceased, Alfred Fehrle and Paul Fritzsche (to Winthrop Chemical Co. Inc.). Can. 386,659, Jan. 30, 1940. Two hydroxyalkyl radicals are introduced by reaction with an alkylene oxide into one of the amino groups of a diaminoarsenobenzene which may contain further substituents in the benzene nuclei, and an alkyl radical is introduced by treatment with an alkylating agent, or a hydroxyalkyl radical, by means of alkylene oxide, and the formaldehydesulfoxylate radical are introduced into the other amino group.

Theobromine alkaline earth metal gluconates. Russel J. Fosbinder (to Maltbie Chemical Co.). U. S. 2,182,-314, Dec. 5. By reaction of CaO, theobromine and Ca gluconate, etc., a double salt of theobromine and Ca with gluconic acid is obtained, which is suitable for use in the treatment of cardiovascular diseases.

Water-soluble derivatives of *p*-aminobenzenesulfonamide. Joseph Ebert (to Farastan Co.). U. S. 2,182,-075, Dec. 5. Salts of *p*-aminobenzenesulfonamide with phenolsulfonic acid, benzenesulfonic acid and sulfosalicylic acid are produced, suitable *for therapeutic use* in treating infections caused by cocci. Details are given of the production of the salt of *p*-aminobenzenesulfonamide with benzenesulfonic acid, m. 213–17° (decompn.), the salt of *p*-aminobenzenesulfonamide with phenolsulfonic acid, m. 216–20° (decompn.), and the salt of *p*-aminobenzenesulfonamide with sulfosalicylic acid, m. 214–20° (decompn.).

Device and operative details for expressing oil from fruit skin. Melville D. Truesdale. U. S. 2,181,674, Nov. 28. Various structural and operative details.

Vitamin preparations. Harden F. Taylor (to Atlantic Coast Fisheries Co.). U. S. 2,183,053, Dec. 12. See Brit. 490,001 (*C. A.* **33**, 814[8]).

Compositions of gelatin with vitamin A, etc. Stanton Reynolds (to Atlantic Coast Fisheries Co.). U. S. 2,183,084, Dec. 12. In making an "activated" gelatin product, in finely divided form, a polyphase dispersion is produced in which liquid droplets of gelatin contg. a vitamin A concentrate or the like dispersed therein, constitute the dispersed phase and a vegetable oil, such as castor oil, constitutes the continuous phase, the droplets are caused to solidify (as by cooling to about 8°), oil is removed by use of an oil solvent such as "industrial methylated spirit," and at least part of the water is removed, as by use of alc. Various details are given.

Derivatives of androstenols. Arthur Serini, Lothar Strassberger and Willy Logemann (to Schering A.-G.). U. S. 2,182,825, Dec. 12. A method for the production of halogenated androstenol compds. involves subjecting androstenolone compds., where the hydroxy group is replaced by a group that, upon hydrolysis, is reconvertible into the hydroxy group, to the action of reducing agents capable of reducing the carbonyl group of the androstenol compds. to the secondary alc. group, substantially without affecting the double bond present in said androstenolone compds. and replacing the secondary alc. group of the androstenediol compd. obtained by halogen. The reduction may be effected with H in the presence of a Ni catalyst or by nascent H produced with use of Al amalgam, and details are given of the production of an acetate of androstenol, m. 144°, a 3-acetoxy-17-chloroandrostene, m. 170°, and a 3-acetoxy-17-bromoandrostene. The products may be used as *therapeutic agents* or as intermediates for the production of other products of the male sex hormone class.

Extractions, such as the extraction of sex hormones

from urine by use of chloroform, etc. Samuel L. Leiboff. U. S. 2,182,564, Dec. 5. App. is described, and an extn. process in which a liquid contg. a substance to be extd. is treated by placing in a first vessel a quantity of the liquid and a quantity of a liquid solvent for the substance, which solvent is immiscible with the liquid and has a higher sp. gr. and a lower b. p. than the latter. A quantity of the liquid solvent is placed in another vessel, the solvents in both vessels are heated whereby the solvents are vaporized and the vaporized solvent in the first vessel passes upwardly through the liquid contg. the substance to be extd. The vapor from the other vessel is passed into the first vessel above the liquid therein, the vapors in the first vessel are condensed above the liquid therein whereby the solvent thus condensed passes by gravity through the liquid and forms a soln. of the substance, and the soln. of the extd. substance is withdrawn from the first vessel into the other vessel.

Sexual hormone. Wilhelm Dirscherl (to Rare Chemicals, Inc.). U. S. 2,182,073, Dec. 5. A male-acting sexual hormone material comprises an ext. such as may be obtained by treating with benzene a wax-like material obtained from a tree bark such as China wax contg. a sterol-type alc. of the group consisting of cinchol, cupreol, quebrachol and rhamnol, the ext. having specific activity on the seminal vesicle of the mouse equal to one M. U. in not more than 100 γ when tested according to Loewe and Voss, but having substantially no activity upon a capon's comb. Cf. *C. A.* **33**, 5132[8]. U. S. 2,182,074 (Wilhelm Dirscherl and Josef Kraus, joint inventors; to the same assignee) relates to an ext. of isocholesterol such as may be obtained from wool fat and which has specific activity on the seminal vesicle of the mouse equal to one M. U. is not more than 100 γ when tested according to Loewe and Voss, but having substantially no activity on a capon's comb.

Germicidal detergent suitable for general use. Milward Bayliss, John L. Wilson and Erling J. Ordal (to Economics Laboratory Inc.). U. S. 2,183,037, Dec. 12. A major proportion of buffer salts such as Na_2CO_3, NaH_2PO_4 or Na silicate is used with a relatively small proportion of a mixt. of active sulfonated wetting agents including a sulfonated alc. wetting agent such as Na lauryl sulfate to form a compn. adapted when dissolved in water in amts. of 0.5–3% to form a *germicidal soln.* contg. a small fraction of 1% of the wetting agents with a sufficient amt. of the alk. salts to give a pH above 11.5. Cf. *C. A.* **33**, 2251[7].

18—ACIDS, ALKALIES, SALTS AND OTHER HEAVY CHEMICALS

E. M. SYMMES

The stability of alkali peroxide solutions. J. M. Martrémont. *Tiba* **17**, 531 7(1939).—A brief discussion of the influence of alky. or acidity, of temp. and of protective agents (soap, pyrophosphoric esters, alk. earth salts of certain alkyl sulfates, alkali stannates). A. Papineau-Couture

Distribution of boron between liquid and solid phases of the Inder Lake (Western Kazakhstan) brines during isothermal evaporation. I. N. Lepeshkov and A. I. Shpikel'man. *Compt. rend. acad. sci. U. R. S. S.* **24**, 707-8(1939)(in English).—A discussion of the problems assocd. with the development and utilization of the Inder Lake brines contg. Ca, Mg, K, Na, B and Br. F. G.

Fundamental mechanics of calcination and hydration of lime and methods of control. Victor J. Azbe. *Am. Soc. Testing Materials, Symposium on Lime* **1939**, 88-102 (1940); cf. *C. A.* **33**, 9556[9].—A discussion from the chem. engineering point of view, including both theory and practical points in design and operation of kilns. The value of lime for many purposes and the smooth operation of the kiln depend largely upon burning conditions, which can be controlled. Most lime is overburned; the first remedy is to reduce the size of stone charged but avoid fines, draw more frequently and provide better trimming facilities. Temp. control by recirculation of hot gases is practically necessary to avoid major difficulties. Errors in burning cannot be corrected completely by modifications of the hydration process; overburned lime is too dense for best results in hydration. C. J. S.

Factors affecting milk of lime employed in industry. D. E. Washburn. *Am. Soc. Testing Materials, Symposium on Lime* **1939**, 36–9(1940).—Chem. lime for prepg. milk of lime should contain at least 90% CaO, 1–3% $CaCO_3$, be mild burned, preferably in a rotary kiln, and slaked rapidly at a low temp. for satisfactory soly. and slow settling. C. J. Schollenberger

How efficient is the lime kiln? Victor J. Azbe. *Rock Products* **42**, No. 12, 43–4(1939).—Methods of calcn. are described. E. H.

Developing methods for the preparation of red lead from galena answering the requirements of the storage-battery industry. L. V. Sakharova and B. E. Levitina. *Trudy Inst. Lakov i Krasok* **2**, 7–22(1939).—The velocity of interaction of $(NH_4)_2SO_4$ with storage-battery red lead in the prepn. of paste depends primarily upon the cryst. structure of the original galena and the degree of uniform fractional oxidation. Only if there has been uniform fractional oxidation will the velocity of setting be a function of the dispersion of the red lead. With red lead obtained from polydispersed galena, the process of setting will be concd. in the coarse, little-oxidized fraction. Red lead for storage batteries must be made by uniform oxidation of galena of the tetragonal system. For uniform fractional oxidation, the galena should be preliminarily sepd. into a fraction consisting of particles smaller than 10 μ and a fraction consisting of particles larger than 10 μ, and these fractions should be oxidized separately and the products mixed in suitable proportion. French red lead is best suited for the storage-battery industry. A. A. Boehtlingk

Magnesia from Canadian brucite. M. F. Goudge. *Can. Chem. Process Inds.* **24**, 3–5, 8(1940).—A brief review of a preliminary report on brucite deposits in Ontario and Quebec and their com. possibilities. Brucitic limestone of suitable grade for com. exploitation is available in the Rutherglen and Wakefield Canadian areas to supply a large part of the present and prospective Canadian market for Mg and its products for many years. Means of identification and recovery of brucite and the cost of production are noted. W. H. Boynton

The technology of titanium dioxide. I. Properties and structure of titanium dioxide and its hydrates. A. M. Brusilovskiĭ, B. E. Boguslavskaya and E. G. Nosovich. *Trudy Inst. Lakov i Krasok* **2**, 23–35(1939).—Dehydration of Ti hydroxides by the van Bemmelen, the Bolte and the thermal methods proceeds without interruptions or breaks, i. e., the Ti hydroxides are not crystal hydrates of a definite structure. These compds. retain water by adsorption (capillary) forces. TiO_2, heated to incandescence, becomes cryst. and is then composed of a mixt. of anatase and brucite; above 1100° there is a transition of anatase and brucite into rutile. **II. Investigation of the adsorptive power of titanic acids.** A. M. Brusilovskiĭ and M. M. Poshvina. *Ibid.* 36–41.—The specific surface of titanic acids can be measured by the method of adsorption with phosphoric acid. At pH 3.83 the amt. of adsorbed phosphoric acid is greater than at pH 2.7 and 1.76; this indicates a smaller particle size of the metatitanic acid obtained at pH 3.83. The proposed method, because of its simplicity, may find practical application in the detn. of the dispersion obtained under manufg. conditions for titanic acid, for the control of the product. A. A. Boehtlingk

The functions of the flotation reagents in the soap flotation of fluorite. Kazuo Kanazawa and Genzo Komparu. *Suiyokwai-Shi* **10**, 79–96(1939).—Flotation expts.

with fluorite ore contg. 7.64% CaF_2 from Hangchow, China, were made. The −65 + 200-mesh fluorite was more floatable than the −200-mesh with small quantities of oleic acid or Na oleate, but the −200-mesh fluorite was floated with larger quantities, about 1000 g./ton of oleic acid or 600 g./ton of Na oleate. This tendency may be due to the fact that the rate of flocculation of the −200-mesh was increased by the addn. of oleic acid or Na oleate. Oleic acid with Na oleate floated more fluorite than oleic acid alone. Small quantities, e. g., about 100 g./ton, of another frother, such as camphor white oil, oleic acid or Na oleate, increased the floatability of fluorite. With 180 g./ton oleic acid, fluorite was most floatable at −150 + 200-mesh and the −100 + 150-mesh fluorite was most floatable at a pH of 9 of the tailing soln., a pH obtained by the addn. of CaO. Na silicate, $CuSO_4$, citric acid or Cr nitrate depressed the flotation of fluorite. Citric acid and Cr nitrate were the most effective depressors. The depressing action of $CuSO_4$ with oleic acid was more marked than with Na oleate. Na_2CO_3, $K_2Cr_2O_7$ or $MnSO_4$ did not depress, but slightly activated, the flotation of fluorite. In the flotation of the ore contg. 48.2% CaF_2 and 35.9% SiO_2 from Zimmu Mine, Hirosima, the max. extn. was obtained with 400 g./ton $K_2Cr_2O_7$, 250 g./ton Na silicate and 200 g./ton oleic acid.

Hideo Nishimura

Decomposition of titanite minerals with hydrochloric acid. A. M. Brusilovskiĭ and N. N. Starosel'skiĭ. *Trudy Inst. Lakov i Krasok* 2, 86-94(1939).- By HCl treatment of titanite minerals a pigment contg. TiO_2, together with filler, is obtained; the product has good com. properties. A 1.2 ratio of HCl to titanite or a max. $1^1/_4$ 2 of the theoretically required amt. is best. The duration of treatment is of minor importance. The titanite concentrate used contained TiO_2 32.3, CaO 22.1, SiO_2 31.2, Fe_2O_3 6.28, and Al_2O_3 6.2%; 20% HCl was used in the decompn. The covering power and other properties of the pigment are discussed and the results described.

A. A. Boehtlingk

Decomposition of titanite in the presence of sodium chloride. A. M. Brusilovskiĭ, M. A. Shtern and I. I. Pankova. *Trudy Inst. Lakov i Krasok* 2, 229-36(1939). —Titanite concentrate can be completely decompd. by the action of the products of decompn. of NaCl with superheated steam. The process can be improved by the introduction of catalysts. The app. should be modified to prevent the carrying off of NaCl. The expts. are described.

A. A. Boehtlingk

Decolorizing carbon and sodium silicate from Philippine carbonaceous rice-hull ash. Aurelio O. Cruz and Augustus P. West. *Philippine J. Sci.* 70, 143-56(1939). —A method of making in one process both decolorizing C and sodium silicate from carbonaceous ash obtained by burning rice hulls is described. This C gave, for saccharine liquids, a C efficiency greater than that of standard C, in one case even greater than suchar C. Treatment of this C only once with NaOH (12°Bé.) gave a very siliceous rice-hull C, which, for ordinary com. purposes, satisfactorily reduced the color of coconut oil. Crude sodium silicate, made in this manner, contained about 2% more alkali than imported silicate, and is good for making soaps, the excess alkali saponifying the fat. By treating the crude silicate with C-free rice-hull ash, the excess alkali is neutralized, and the product had about the same compn. as an imported sodium silicate.

R. K. Carleton

Primary stages in formation of platinum black. D. L. Berdichevskaya and P. D. Dankov. *Compt. rend. acad. sci. U. R. S. S.* 24, 545-8(1939)(in English); cf. *C. A.* 28, 5323[1].—Metallic Pt is formed from Na_2PtCl_6 and CH_2O in 2 stages: (1) the slow formation of nuclei (induction period) and (2) the quick pptn. of metal in the presence of the nuclei already formed. The induction period is increased by previous removal of dust from the soln., by decrease in temp., and by decrease in the concn. of the reagents, the process being checked at low temps. in the absence of dust. With decrease in concn. of the reagents, a concn. is reached below which the induction period increases sharply.

George Ayers

Evaluation of C black by rate of cure and extrusion (Johnson) 30. Lime in base-metal flotation (Rose) 9.

Flow Carbon; the Story of Pellet Black, Its Development, Perfection and Use. New York: Columbian Carbon Co. 82 pp.

Silica in Industry; Microsil Ground Silica, Blackhawk Silica Sand. Chicago: Standard Silica Corp. 27 pp.

Double fluorides of alkali metals and aluminum. Harold W. Heiser (to Aluminum Co. of America). U. S. 2,182,509, Dec. 5. See Fr. 838,351 (*C. A.* 33, 7969[3]). U. S. 2,182,510 relates to a method in which a soln. of a hydrofluoboric acid compd. is treated with materials dissocg. to form Al and alkali metal ions in the soln., in proportions effecting the pptn. of a double fluoride.

Nitrates such as sodium nitrate. Herman A. Beekhuis, Jr. U. S. 2,181,559, Nov. 28. An arrangement of app. is described, and a process for the production of a nitrate by heating a reaction mixt. of HNO_3, water and metal chloride to its b. p. to cause the acid and chloride to react to form metal nitrate and evolve a moist gaseous mixt. substantially consisting of water vapor, NOCl and Cl; this involves passing the evolved NOCl and Cl with accompanying water vapor in direct contact with aq. HNO_3 contg. 40% or more HNO_3, all of which aq. HNO_3 is introduced into contact with the moist gaseous mixt. at a temp. of 30° or lower, bringing the HNO_3 into contact with the moist gaseous mixt. without extraneously heating the HNO_3, thereby cooling the gaseous mixt. and condensing therefrom most of the water vapor contained therein, withdrawing from contact with the acid a gaseous mixt. substantially consisting of NOCl and Cl, then incorporating the resulting HNO_3 soln., contg. the water condensed from the gases, in a reaction mixt. of HNO_3, water and metal chloride which is heated to its b. p. to form addnl. metal nitrate, NOCl and Cl. Cf. *C. A.* 33, 39777.

Alumina from bauxite, etc. Rudolf Scholder. U. S. 2,181,669, Nov. 28. An aluminiferous material such as calcined bauxite is decompd. with a liquor contg. an alkali metal oxide and a halide such as NaCl, NaBr, KCl or KBr, the halide and oxide being in about the ratio of 1:3, resp., to form an aluminate liquor, in which the alkali metal oxide is present in such proportion as to maintain a ratio between it and the Al_2O_3 of between approx. 1.5:1 and 1.1:1. The decompn. may be effected by heating for several hrs. at 180°.

Aluminum silicate compositions suitable for use with glue, rubber, clay, etc. Charles E. Kraus. U. S. 2,182,086, Dec. 5. There is formed a jelly-like oil and water colloidal suspension of Al silicate, produced by agitating together naturally occurring colloidal amorphous Al silicate naturally impregnated with mineral oil, in which the colloidal properties of the Al silicate are masked and the mass cannot be deflocculated by mech. grinding in water, with an aq. soln. of an electrolyte such as a dil. NH_4OH soln. at a temp. of about 88°, and cooling the resulting modified mixt.

Ammonia production from ammonium sulfate. Edward P. Fleming and Melville F. Perkins (to American Smelting and Refining Co.). U. S. 2,182,078, Dec. 5. A process for obtaining pure, concd. aq. NH_3 involves grinding NH_4 sulfate crystals with lime and water in a gas-tight closure, the water being in an amt. insufficient to dissolve the bulk of the crystals, continuously passing steam into direct contact with the reacting materials and withdrawing ammoniacal vapors, rectifying the vapors, and condensing the enriched vapors. App. is described.

Mono-calcium phosphate. Louis Block and Charles S. King (to Blockson Chemical Co.). U. S. 2,181,933, Dec. 5. A process of making mono-Ca phosphate monohydrate involves subjecting di-Ca phosphate dihydrate of the granulation characteristics desired for the resulting

mono-Ca phosphate within the range of 60 to 250 mesh, to the converting action of a liquid medium contg. essentially an inert liquid diluent such as acetone and H_3PO_4 at least in sufficient quantity to react with the material to form the mono-Ca phosphate monohydrate and without dissolving the treated material or product. 1

Granular calcium phosphate. Augustus H. Fiske (to Rumford Chemical Works). U. S. 2,182,613, Dec. 5. A method of forming, from a "commercially pure" H_3PO_4 which is free of metallic compds., a mono-Ca phosphate contg. a relatively large proportion of granular nonfriable product to soft pulverulent product involves treating a sol. phosphate of Fe, Al or Cr with H_3PO_4, lime and water in suitable proportions to furnish approx. 1.25% of the Fe, Al or Cr in the final product. 2

Silicon carbide grains. Abraham A. Klein (to Norton Co.). U. S. 2,183,044, Dec. 12. Silicon carbide grains have their strength improved by heating them to 1000–1400° and holding them at such temp. for a considerable time (suitably several hrs.) while oxidation is limited (as by use of an inert atm.) so as to produce substantially smooth, nonpitted, lustrous surfaces, followed by cooling slowly to anneal the grains and prevent detrimental strains being set up in them. 3

Separating carbon dioxide from gaseous hydrocarbons. Ludwig Rosenstein (to Shell Development Co.). U. S. 2,182,305, Dec. 5. For recovering CO_2 from normally gaseous hydrocarbons of less than 5 C atoms, such as propane mixts., by treatment with an aq. soln. of K phosphate, the hydrocarbons, while in the liquid state, are brought into contact with an aq. K_3PO_4 soln. under conditions maintaining the materials in the liquid state, and CO_2 is recovered from the resulting soln. by steaming. 4

Extracting fluorine values from fluorspar ores. Harold W. Heiser (to Aluminum Co. of America). U. S. 2,182,511, Dec. 5. A fluorspar ore is digested with an aq. soln. of H_2SO_4 (suitably of about 10–20% strength and at a temp. of about 70–100°) contg. boric acid or a borate.

Hydrogen production by reaction of water with a metal such as iron. Walton H. Marshall, Jr. (to M. W. Kellogg Co.). U. S. 2,182,747, Dec. 5. An arrangement of app. is described, and a method of continuously generating H by the reaction of water in the liquid phase and a finely divided metal such as Fe at temps. of about 230–370° in a reaction zone wherein a pressure is maintained above the vapor pressure of water at the reaction temp., gaseous products being continuously removed from the reaction zone, metal oxide formed being removed and fresh finely divided metal being supplied and water being continuously supplied to the reaction zone (H being recovered from the gaseous products).

Ore concentration. Benjamin R. Harris. U. S. 2,182,845, Dec. 12. An ore pulp, such as one of sylvite and halite, contg. KCl and NaCl is subjected, in a substantially satd. brine, to a froth flotation treatment in the presence of octyl sulfate or its sol. salts.

Apparatus for agglomeration of carbon black. Howard W. Price. Can. 386,813, Feb. 13, 1940.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

The internal binding energy and constitution of glass. I. The viscosity of glass at temperatures near the transformation point. Taro Moriya. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 357(1939).—Measurements of viscosity, carried out by detg. the elongation rate of glass fiber subjected to longitudinal tension, show that the relation between log η and $1/T$ is represented closely by two straight lines that break at a temp. called the transformation temp. (near transformation temp. obtained from thermal expansion measurements), where the coeff. of viscosity is approx. 2.4×10^{14}. **II. The viscosity and internal binding energy of soda-silica glasses.** *Ibid.* 357–8.—Based on data obtained for several soda-silica glasses, the binding energy (derived from the slope of the straight lines of the curve log η *vs.* $1/T$) above the transformation temp. is different from that below the transformation temp. At temps. above the transformation point, the binding energy decreases with increasing SiO_2 content, while at temps. below the transformation point, it increases with increasing SiO_2 content. **III. The viscosity and internal binding energy of Na_2O-B_2O_3-SiO_2 glasses.** *Ibid.* 367.—The binding energy increases with increasing B_2O_3 content both above and below the transformation temp. **IV. The internal binding energy of glass and the glassy state.** *Ibid.* 367.—From the exptl. data of previous reports, as well as of other workers, the probable internal binding energy-temp. curves for a series of soda-silica glasses have been examd. for a wide temp. range. From considerations of the "glassy state," the compd. Na_2O.SiO_2 may exist at high temp. in soda-silica glass. George Ayers 7 8

The influence of silica on the gas content of glass melts (displacement of SO_3 by SiO_2). H. Jebsen-Marwedel. *Glastech. Ber.* **17**, 325–7(1939).—Analysis of a series of soda-lime-silica glasses with 2% of the Na_2O introduced as sulfate shows that, with increasing SiO_2 content, there is a proportionate drop in SO_3 content. This displacement of SO_3 as soln. of SiO_2 progresses is an important factor in gas evolution and fining. J. F. Hyde 9

A glass containing cadmium sulfide. I. K. Huwa and H. Inuzuka. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 296(1939).—Glass contg. added CdS and analyzing 1.20% Cd, 0.35% total S and 0.30% "sulfide" S, when heated approx. 1 hr. at 750°, acquires a slightly yellowish milky appearance; increase in temp. increases the yellowish milky opaqueness until at 1000° a transparent greenish yellow glass is obtained. X-ray photographs of the glass samples which were heated at temps. from 550° to 1000° show the same lines as those of α-CdS, while those of the glass samples heated at 1000° or above do not contain these lines. George Ayers

Propane and acetylene in lamp-working shops. Theo. Ziener. *Glastech. Ber.* **17**, 329–35(1939). J. F. Hyde 6

Further developments in the testing of materials and properties. Heinz Mields. *Ber. deut. keram. Ges.* **20**, 508–17(1939).—A review of 10 years of ceramic testing. 259 references. P. S. Roller

Special bricks that are necessary in war time. (chromite refractories). Josef Robitschek and Felix Singer. *Brit. Clayworker* **48**, 310–14(1940).—A review of data concerning silica, fireclay, high Al_2O_3, chromite, forsterite, magnesite and dolomite refractories. E. C. Petrie

Thermal tests and calculations on drying in the brick industry. Heinz Roth. *Ber. deut. keram. Ges.* **20**, 427–47, 457–76(1939).—The thermal efficiencies for a large room, a chamber and a tunnel dryer were, resp., 62, 48 and 21%, while the air efficiencies were 93.5, 97.8 and 78%. P. S. Roller

Beryllium and beryl in the ceramic industry. L. Guimin. *Rev. matériaux construction trav. publics* **1939**, 85–7B. P. S. Roller

The recrystallization of alumina. Eugen Ryschkewitsch. *Ber. deut. keram. Ges.* **20**, 477–84(1939); cf. *ibid.* **16**, 111(1935).—Calcined Al_2O_3 occurs as small flaky grains. In a cast slip, the grains nearest the wall are oriented parallel to it, and even in pressed articles an orientation is observed. Recrystn. occurs rapidly above 1800°, sometimes along the *c* axis, so that the original platy material takes on a prismatic structure. However, usually the recrystn. is regular. Mineralizers facilitate recrystn., but as a fine-grain structure is desired in ceramics, mineralizers are to be avoided, especially TiO_2 and ZrO_2. In tech. ware, gas inclusions are frequently present in the crystallites, but as these are sealed, impermeability is high. Because of the tendency for crystn. to take place

around an air space, a capillary hole as for a spinning die, retains its original dimensions after firing. P. S. R.

The reaction between burnt kaolin and lime in aqueous solution. W. Strätling. *Ber. deut. keram. Ges.* **20**, 522–7 (1939).—Total heat of reaction of Zettlitzer kaolin and $Ca(OH)_2$ consists of heat of wetting and heat of adsorption or reaction. The latter, as well as total heat, showed a max. for kaolin burnt at 500°, while the heat of wetting decreased continuously. The surface area, calcd. from size analysis, also decreased from 34,000 sq. cm./g. at 110° to 9200 at 500° and 5800 at 1100°. The amt. of CaO taken up in 111 hrs. and subsequently forming satd. soln., was greatest for the product burned at 700°. On evapn. of the mother liquor of the reaction with the 500° to 800° product, spherulitic crystals with n equal to 1.53 and of compn. 3 $CaO.Al_2O_3.12H_2O$, and in one case $3CaO.Al_2O_3.18H_2O$, were obtained. The solid phase was a new quaternary hydrate of CaO, Al_2O_3 and SiO_2, probably in the ratio of 2:1:1. This compd. according to x-ray, was also obtained in the reaction of $3CaO.Al_2O_3$, SiO_2 sol and $Ca(OH)_2$, but not when $3CaO.Al_2O_3.6H_2O$ was used, owing to the slowness of the reaction. P. S. Roller

California pottery manufacturers now use local china clays. Howard R. Erwin. *Ceram. Ind.* **34**, 56, 58(February, 1940).—Compn. and properties are compared with English type VC No. 1. Herbert S. Willson

Increase of the stability of unburned clay in the firing of porcelain articles. G. K. Tereshchenko. *Stroitel. Materialy* **1938**, No. 8-9, 50-3; *Khim. Referat. Zhur.* **2**, No. 4, 104-5(1939).—Conditions for increasing the bending strength of dry clay were investigated by the addn. of different admixts. to the porcelain mass: mineral acids, liquid glass, tanning ext., joiners' glue, bentonite, etc. Masses contg. sulfite-cellulose ext., molasses, dextrin and starch were found to yield dry clay which was fairly strong and which absorbed very little water. As a result of these investigations a conclusion was reached that dry clay can be glazed by the immersion method. The use of admixts. to improve the mech. properties of dry porcelain clay is recommended for articles which require firing.
W. R. Henn

The relative behaviors of porous and densely burned porcelain insulators in high-frequency electric fields. Werner Endres. *Keram. Rundschau* **47**, 443–5, 465–6, 483–5, 501-3, 519–21, 527-8(1939).—The presence of pores and small cracks results in a decrease in dielectric loss and dielectric const. As a result, when dry, the porous product is less heated in a condensor field by a high-frequency voltage. However, in the presence even of traces of moisture, the reverse is true. P. S. Roller

Control of soluble metallic salts results in uniform colors. John H. Grady. *Brick & Clay Record* **96**, No. 2, 31(1940).—These sol. salts have several advantages over colored glazes for polychrome decoration. Aqueous solns. of most of the sol. salts have a pH lower than 7.0 and metal parts cannot be used in painting or spraying. When exposed to the atm. these salts, being deliquescent, condense a film of moisture on their surface and the film soon becomes a satd. soln. by dissolving the solid. The process will continue until all the salt has dissolved. Watering of the various salts greatly increases the difficulty of prepg. uniform solns. E. C. Petrie

Choosing refractories. Bernard Thomas. *Proc. Staffordshire Iron Steel Inst.* **54**, 16–29(1938–39); cf. *C. A.* **33**, 1116[2].—Typical refractories found to give the most economic service are: (*a*) For low-temp. solid-fuel furnaces, various grades of Stourbridge firebrick with 53–70 SiO_2 and 25–39% Al_2O_3; (*b*) for high-temp. solid-fuel furnaces, aluminous series contg. 51–53 SiO_2 and 42–44% Al_2O_3; (*c*) siliceous type refractory for high-temp. stoker-fired furnace contg. 89.50 SiO_2 and 8.10% Al_2O_3 and having a refractoriness of 1670° and a porosity of 26.4%. (*d*) Chrome Spinel type of refractory contg. 35–39 MgO, 24–25 Cr_2O_3, 16–17 Al_2O_3, 14 FeO, 5–7% SiO_2, and a refractoriness under load, of 1560–1650° with a porosity of 19–22%. G. T. Motok

Soaking-pit refractories. Everett C. Hite and Gilbert Soler. *Brick & Clay Record* **96**, No. 1, 62–3; No. 2, 60, 62(1940).—A discussion. E. C. Petrie

The fluidity of low-melting mixtures of some oxides of importance in the slagging of refractories. K. Endell and G. Brinkman. *Ber. deut. keram. Ges.* **20**, 493–507(1939); cf. *Ibid.* **19**, 49(1938).—In the systems CaO or MgO–Al_2O_3–SiO_2 and CaO–FeO(Fe_2O_3)–SiO_2, the viscosity increased with increase in SiO_2 and in Al_2O_3. The FeO system was by far the most fluid. At 1500° the viscosity was related to the ratio $CaO/SiO_2 + Al_2O_3$, and the viscosity of basic and acid slags at 1400° was found to be given in terms of this ratio. Mg, Fe and Ti formed exceptions to the rule that with decrease in ion radius the fluidity increases; this was explained by a stiffening effect caused by replacement of Al in the lattice by these ions. On the other hand, they can split up SiO_2 tetrahedra and thereby exert a contrary liquefying effect. P. S. Roller

The application of lead- and boron-free whiteware glazes. W. Funk. *Ber. deut. keram. Ges.* **20**, 484–9 (1939).—A lecture. P. S. Roller

The characteristic nature of the glaze of Japanese earthen wares and porcelains. Eiiti Koizumi. *J. Chem. Soc. Japan* **60**, 1242–6(1939); cf. Koizumi, *C. A.* **33**, 7509[7].—Analyses of porcelain glazes from the Kyushu district are given. T. Katsurai

Chemistry and vitreous enamels. Emerson P. Poste. *Ind. Eng. Chem.* **32**, 9-15(1940).—The sheet iron must contain less than 0.20% C. Six % H_2SO_4 is used for pickling and is discarded when the concn. of solids reaches 6%. Ware is neutralized with a 0.3% hot soln. of Na_2CO_3 or mixts. of Na_2CO_3 and borax. Nickel dip (pH control between 5.5 and 6.0, very essential at a temp. of 150–180°F. for 5 min.) after pickling (3 oz. of $NiSO_4.6H_2O$ plus 0.25 oz. of boric acid per gal.) prevents many enameling troubles. Four % water vapor in the furnace atm. may cause defects. As little as 0.5% acid gas may also produce trouble. A. W. King

Basis of European enamels. Gruenwald's formulas. Helen Hirsch. *Ceram. Ind.* **34**, 60, 62 (February, 1940).—Enamels for iron and steel. Herbert S. Willson

Use of white arsenic in the enameling industry. M. Dechigi. *Arch. Gewerbepath. Gewerbehyg.* **7**, 468–76 (1936); *U. S. Pub. Health Eng. Abstracts* **18**, IHS, 5 (Feb. 19, 1938).—Originally in Italian majolica a mixt. of ZnO and PbO was used for white glazes. In recent years, because of lower cost, oxides of As and Sb have been used. The danger of As poisoning is noted. C. R. F.

Influence of climatic conditions on enamelling. Berthold Deutsch. *Foundry Trade J.* **62**, 12–5(1940).—The processes mainly affected by climatic conditions are pickling, milling, aging, the application of the enamel slip, drying and firing. I. Hartmann

Eliminate tearing, aid enamel set by plant control of mill liquor. T. D. Hartshorn. *Ceram. Ind.* **34**, 50, 62 (February, 1940). Herbert S. Willson

---

App. for detg. chem. attack on glasses (Nagaoka) 1. Sprung-arch roofs of high-temp. furnaces (McDowell) 9. Al silicate compns. for use with clay (U. S. pat. 2,182,086) 18.

Thiene, Hermann: Glas. Bd. II. Jena: G. Fischer. 755 pp. M. 50.

Apparatus for bending glass sheets. Ormond H. Paddock (to Libbey-Owens-Ford Glass Co.). U. S. 2,182,448, Dec. 5. Various structural, mech. and operative details.

Lehr for annealing glassware. Francis E. Dorsey (to Hartford-Empire Co.). U. S. 2,182,173, Dec. 5. Various structural and operative details.

Heating and pressing apparatus for manufacture of safety glass with use of a finely divided plasticized resin composition and glass plates. James H. Sherts and Brook J. Dennison (to Pittsburgh Plate Glass Co.). U. S. 2,182,358, Dec. 5. Various structural, mech. and operative details.

Recovery of wastes from glass grinding and polishing.

Rob R. McGregor (to Norbert S. Garbisch). U. S. 2,182,384, Dec. 5. A process of producing relatively pure, substantially Fe-free, mixts. of intimately assocd. and very finely divided silica and glass suitable for use as a combined source of silica and cullet in a glass batch, as a substitute for both ground flint and feldspar in a ceramic body and similar purposes, from waste sand produced in the grinding of the surface of glass plates with sand of glass-batch purity, the waste sand contg. substantial amts. of iron added by the grinding operations and being of a particle size such that at least about 90% of it will pass through a screen of about 325 mesh, comprises treating the sand sludge while fresh from the grinding operation by means of a magnetic separator to take out metallic iron particles, then treating it with a soln. consisting of a strong mineral acid and water, the acid being of a concn. of not substantially greater than 10% and being in an amt. sufficient to take out substantially all of the free Fe and Fe compds. remaining in the wastes, then washing out the dissolved iron and freeing the wastes of excess water.

Apparatus for forming pyrometric cones. Geo. A. Bole and Harry E. Co Van (to Standard Pyrometric Cone Co.). U. S. 2,181,618 and U. S. 2,181,619, Nov. 28. Various structural, mech. and operative details.

Transferring photographic designs to ceramic ware. Walter D. Ford. U. S. 2,181,452, Nov. 28. A method of transferring a relief or intaglio design carried on a substantially flat surface to a curved or irregular surface involves distributing a moldable thermoplastic material such as a wax in a heated fluid state on a substantially flat design-contg. surface of a primary mold, allowing the moldable thermoplastic material to cool and solidify to form a flexible matrix bearing in one surface thereof the design of the primary mold, removing the matrix from the primary mold following such cooling and solidification and placing it on a shaping form which possesses the cross-sectional configuration of a final design-receiving surface, the design-contg. surface of the matrix being arranged in direct contact with the shaping form, producing an intermediate mold from the shaping form with the matrix inlaid in one surface of the intermediate mold and with the design-contg. surface of the matrix exposed to the outside of the intermediate mold, and molding a final pattern mold from the matrix-contg. surface of the intermediate mold. Cf. *C. A.* **33**, 3988[5].

Flexible abrasive sheet. Donald E. Edgar and Harry G. Stauffer (to E. I. du Pont de Nemours & Co.). Can. 386,601, Jan. 30, 1940. The abrasive material is bound to the base sheet by a coating consisting of urea-formaldehyde-alc. resin 30–50 and castor oil modified alkyd resin 35–50 parts. The resin contains aliphatic monohydric alc. in combined form in amt. of about 0.5 mol. of alc./mol. of urea.

Coating sheets such as those of iron or steel with vitreous enamel. Archer L. Matthes. U. S. 2,182,132, Dec. 5. A sheet of metal having a smooth surface on one side and a relatively rougher surface on the other side is coated on both sides with a ground coat of fusible enamel, which is fused, and a second coat of enamel is applied and fused onto the coat adjacent the smooth surface.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Ferrari cement and the actual trend of the industry of hydraulic cements. F. Ferrari. *Atti X° congr. intern. chim.* 4, 216–21(1939)(in Italian).—Ferrari cement, because it contains Al_2O_3 and Fe_2O_3 in related equivalents, possesses high mech. resistance, low heat of hydration, min. coeff. of expansion, high chem. resistance and rapid setting. It answers all the needs for modern construction and, because of its low SiO_2 content, offers distinct manufg. advantages. It should replace portland and special cements in all countries. Henri Marc

Cements with blast-furnace slag base. E. L. Dupuy. *Atti X° congr. intern. chim.* 4, 642–9(1939)(in French).—D. reviews the compn. of blast-furnace slag ($Al_2O_3.5CaO.3.5SiO_2$), discusses the addn. of CaO and of $CaSO_4$ and gives data on the effect of these 2 ingredients. $CaCl_2$ satn. takes place when fixed $CaCl_2$ is 0.92 times the wt. of Al_2O_3, giving $CaCl_2.Al_2O_3.3CaO.nH_2O$; with $Ca(NO_3)_2$, $Ca(NO_3)_2.Al_2O_3.3CaO$ is obtained. All the slag can react completely, giving complex aluminates of 2 types, with either 1 mol. or 3 mols. of Ca salts. Henri Marc

Remarks on lime-pozzuolana mortar. F. Parissi and A. Cereseto. *Atti X° congr. intern. chim.* 4, 670–5(1939)(in Italian).—A study of the effects, on the strength of lime-pozzuolana mortars, of the origin of the pozzuolana and its fineness, of the fineness, chem. compn. and formation of the lime, of the amt. of H_2O used in the mortar and of the ratio of CaO to pozzuolana. Data given show that the greatest strength in the range of proper workability is developed when a ratio of lime to pozzuolana is 1 to 3, and for that mix when the ratio of H_2O to dry mortar is 3 to 10. Henri Marc

Lime-pozzuolana mortars in maritime works. C. Vittori. *Atti X° congr. intern. chim.* 4, 676–86(1939) (in Italian).—Mortar made from lime and natural pozzuolana can be improved in physical properties by grinding the pozzuolana. Even better setting properties and uniformity are obtained when 100 to 200 kg. of cement per cu. m. is added to the pozzuolana-lime mixt. Compression tests on samples of concrete made from this "bastard mortar" show that the resistance to compression is still increasing after 5 years in fresh and in salt H_2O. This mortar should be very suitable for maritime construction. Henri Marc

Mechanical strength of mortars stored in sulfate solutions. G. Baire. *Rev. matériaux construction trav. publics* **1939**, 177–9.—The strength of all mortars continued to increase during 2 yrs. but frequently was less than in pure water. $MgSO_4$ was most harmful, and the more so the greater the content of lime in the cement. The effect of $CaSO_4$ was not always related to the lime content. Gaize and slag cements were little affected. P. S. Roller

Vacuum concrete. Jacob J. Creskoff. *Can. Engr.* **77**, No. 23, 4–8(1939).—This process removes a large part of the excess water from the mix after it has been placed in the forms and simultaneously compacts the concrete. The concrete at the wearing surface is the strongest and toughest. The technique of the process is described. Ann Nicholson Hird

Review of road-tar uses in 1939. G. E. Martin. *Roads and Streets* **83**, No. 1, 63–4, 66(1940); cf. *C. A.* **33**, 9577[4].—M. gives the standard designations of road tars and reviews their uses in skid-resistance surfacing, tar-base stabilization, tar-shoulder maintenance and residence-street pavements. Henri Marc

Stabilized base construction on Mississippi's route 15. An outline of construction problems and their solution. A. B. Covell. *Roads and Streets* **82**, No. 9, 23–9(1939).—A detailed description of the construction of 2 sections of asphalt-stabilized base; particular emphasis is placed on the control of moisture on the windrowed material before rolling. Henri Marc

Method of testing the toxicity of wood preservatives to fungi. *Brit. Eng. Standards Assoc.*, Comm. Rept. **838**, 1–17(1939); *Rev. Applied Mycol.* **18**, 829–30.—Detailed directions are given for testing the toxicity of timber preservatives by the standard block method. In a test cited as an example of the evaluation of results, the toxic limits (toxic points), i. e., the interval between the concn. just permitting decay and that next highest in the series completely inhibiting it, for creosote are given as 4 to 6, 4 to 8, about 12, and about 5 kg. per cu. m. for *C. puteana*, *Poria vaporaria*, *L. lepideus*, and *Polystictus versicolor*,

resp., the corresponding figures for NaF (excluding *P. versicolor*) being 0.5 to 0.7, 0.2 to 0.4, and about 0.1, resp. Tested against *C. puteana*, 0.06 and 0.08% NaF preserved pine sapwood in a sound condition for 4 months at 22° (the former concn. allowing slight superficial growth), at 0.04 incipient decay set in (4.7% loss of dry wt.), while the blocks in the 0.02 and control series were completely rotted (42 and 49.5% loss of wt., resp.). O. E. S.

Determination of fluorine in wood-preservation technique. II. Determination of fluorine in wood. B. Ikert. *Chem.-Ztg.* **63**, 754, 755(1939); cf. *C. A.* **33**, 5624[1].—An approx. detn. of F in wood can be obtained by the usual zirconium-alizarin test but for accurate results the following procedure is recommended: Take 50 g. or less of the wood, cut into pieces of about the size of a match and moisten well with a soln. contg. 6% $Ca(OAc)_2$ and 30% $Cr(OAc)_3$. Keep about 15 min. under a vacuum. Then dry at 120-140° and transfer to a quartz dish whose bottom is covered with a uniform layer of about 2 g. pulverized quartz. Heat the mixt. until the wood is entirely decompd. leaving an ash of black charcoal. Transfer to a small distg. flask, of which the side tube has 2 downward bends and the neck is provided with a ground-glass stopper. Add 25 ml. of water and 15 ml. of concd. H_2SO_4, stopper the flask tightly and heat the contents. Catch the distillate, which contains the F as H_2SiF_6, in a flask contg. 5 ml. of 30% NaOH and sufficient water to seal the exit tube from the condenser. Continue the distn. until finally H_2SO_4 fumes are evolved copiously and the charcoal is all oxidized. The distillate should remain basic. To the distillate add 10 ml. of 30% H_2O_2 and evap. to 30 ml. This oxidizes all H_2SO_3. Cool, make acidic to phenolphthalein with HCl, add 1 ml. of Na silicate soln. contg. about 0.03 g. of silicate and then proceed with the F detn. as described in the previous paper, but increasing the vol. of EtOH from 30 to 40 ml. in pptg. the K_2SiF_6. Good results were obtained in test analyses. The method of Willard and Winter (*C. A.* **27**, 681) was found to be nearly as accurate and appreciably shorter than the gravimetric method. The method is applicable not only to wood but to all F compds.

W. T. H.

Chemical seasoning of overcup oak. W. K. Loughborough. *Southern Lumberman*, Christmas issue, **159**, 137-40(1939).—The mechanism of chem. seasoning of wood as applied to overcup oak is described. Lumber is soaked in a concd. or satd. soln. of a chemical capable of appreciably depressing the vapor pressure of water. Diffusion of the chemical occurs into the outer zone of the wood. Because of the effect of the chemical on the vapor-pressure gradient, the wood upon subsequent drying "dries from the inside out instead of from the outside in." Data are given for the diffusion of NaCl into the green wood and the effect of various subsequent drying schedules on the quality of the product. This seasoning method is shown to decrease seasoning times and greatly to improve the quality of the seasoned product. A. J. S.

Asphalt rock from Dubrovnik [for road-making] (Schwarz) 8. Corrosion of Al in mortar (Tronstad, Veimo) 9.

Rader, L. F.: Mills' Materials of Construction. 5th ed. New York: J. Wiley & Sons. 564 pp. $4.00.

Withey, M. O., and Aston, J.: Johnson's Materials of Construction. 8th ed. New York: J. Wiley & Sons. 867 pp. $6.00. Reviewed in *Mech. Eng.* **62**, 79(1940).

Felted asbestos-cement products. Ernest W. Rembert and Dominic Bertogliat (to Johns-Manville Corp.). U. S. 2,182,353, Dec. 5. App. is described, and a method of manufg. a felted product suitable for use in sheet or pipe form which involves forming a dry mixt. of asbestos fibers and portland cement, adding to the dry mixt. a sufficient quantity of water to form a dil. aq. suspension of asbestos fibers and portland cement contg. 20–50 parts of water to 1 part of asbestos and cement, forming a thin felt from the dil. suspension thus formed within ten min. of the time of addn. of the water to the dry mixt., and compositing the felt upon itself to produce a laminated composite asbestos-cement tube.

Cement mixture suitable for molded products or coatings. André M. Fleuret (to Établissements Rouzaud & Fils). U. S. 2,182,291, Dec. 5. A Th compd. such as Th sulfate is used in mixt. with a magnesia cement, and serves to improve setting and stability.

Lining and coating metal pipes with bituminous material. Oscar G. Goldman. U. S. 2,182,227, Dec. 5. A method of applying protective coatings to metal pipes such as large water pipes comprises rotating a pipe on a horizontal axis while applying heat to bring the temp. of the pipe to about 93–205°, then while the hot pipe is revolving at a speed insufficient to throw off the material applying a thin quick setting coat of hot molten bituminous material to the exterior wall of the pipe, then when sufficiently set speeding up the rotation and applying a thick layer of molten bituminous material to the interior of the pipe for smoothing out by centrifugal action, setting the internal layer by the application thereto of a cooling fluid, slowing down the rotary speed of the pipe and building up the thickness of the external layer of bituminous material by further application of the hot molten material while the pipe is slowly revolving.

Coating pipes such as underground pipe lines. Albert C. Bean and Joseph B. Ray. U. S. 2,181,361, Nov. 28. A method of coating underground metallic pipes involves the steps of applying a coating of portland cement incorporated in boiled linseed oil by the aid of a water-insol. metallic soap of an org. acid directly to the metal of the pipe, permitting the coating to set and then applying thereover a second coating comprising pitch contg. a minor proportion of a fibrous binding.

Cement suitable for lining pipes, etc. Joshua C. Witt. U. S. 2,182,714, Dec. 5. A cement clinker of approx. the compn., SiO_2 15.17, Al_2O_3 8.72, Fe_2O_3 12.73, CaO 61.39 and MgO 1.29%, is used with blast-furnace slag and gypsum.

Paving. Raymond F. Bacon and Isaac Bencowitz (to Texas Gulf Sulphur Co.). U. S. 2,182,837, Dec. 12. A plastic compn. comprising S and asphalt is applied as a surface coating and the exposed surface of the coating thus formed is burned to effect reaction between the S and asphalt in the surface portion of the coating, so that a hardened and nonskid surface is produced.

Cold glazing preparations. Stanley R. Lane. Brit. 507,911, June 20, 1939. A prepn. for application to wall surfaces, etc., consists of a substance contg. or capable of forming a sulfate, e. g., Fe alum, $CaCl_2$, cement or a cement and aggregate mixt. and a waterproofing agent, e. g., a metallic soap, with or without pigment. The mixt. is mixed with H_2O for use.

Sound-absorbent composition suitable for use on walls. John G. Britton. U. S. 2,182,535, Dec. 5. A rigid, flameproof and infusible, sound-absorbent product is formed from 8 parts each of an oxide and chloride of the same metal such as those of Mg, together with comminuted bagasse fiber 5, glue 1.5 and water 20 parts, with voids formed by occluded air constituting about 50% of its volume.

Wood-preserving compositions. Ira Hatfield (to Monsanto Chemical Co.). U. S. 2,182,080, Dec. 5. A non-blooming liquid coating and impregnating compn. for treating wood or other cellulosic materials, to protect them from mold and decay, comprises a chlorinated phenol dissolved in a solvent such as a petroleum fuel oil together with a resinous material (such as rosin 5%) in sufficient concn. to prevent blooming. U. S. 2,182,081 relates to generally similar compns. contg. a rosin ester (such as ester gum 5%) to prevent blooming.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND A. GEORGE STERN

Suggested nomenclature for fuels, combustion phenomena, and engine fouling in internal-combustion engines. G. D. Boerlage and K. C. A. Bauman. *IIme Congr. mondial pétrole* **4**, Sect. 5, 281–91(1937).—Engine terms commonly used are set up according to subject matter and the equiv. terms in French and German are 2 given in parallel columns. E. J. Mahler

Availability and characteristics of aviation safety fuels. Robert E. Ellis and Wm. J. Sweeney. *Natl. Petroleum News* **32**, R-18–19(1940).—Ten million bbl. per year of aromatic-type aviation fuels with a min. flash point of 100°F. are potentially available. Little is definitely known about the paraffinic type. C. H. Brooks

Fuel injection and pulverization. Plessis. *Bull. assoc.* 3 *franç. techniriens pétrole* No. **50**, 75–82(1939).—General considerations on the problem of injection, types of injectors and their disadvantages are briefly reviewed. E. J. Mahler

High-speed Diesel engine and its fuel. Hirosi Ōigawa. *J. Fuel Soc. Japan* **18**, 1022–1108(1939).—A lecture. F. I. Nakamura

Combustion in the Diesel engine. de Sermoise. *Bull.* 4 *assoc. franç. techniciens pétrole* No. **47**, 117–56(1939).—The results obtained in recent years in the study of the relationship between complete combustion and the utilization of the latent heat of combustion contained in the injected Diesel fuel as dependent upon fuel properties and engine design are reviewed. The subject is considered in 3 sections: the general characteristics of combustion proper, special study of the influence of fuel characteristics, and the effect of the nature of the com- 5 bustion chamber. E. J. Mahler

Can the hydroxylation theory of combustion be applied to modern furnaces? J. R. Darnell. *Refiner Natural Gasoline Mfr.* **19**, 53–4(1940).—Owing to the high temps. in the com. furnace, lab. combustion data are not applicable. From an analysis of published work, the hydroxylation theory does not apply strictly. C. H. Brooks

Fuel economy in a large British metallurgical plant: The Normanby Park (Scunthorpe, Yorkshire). Ch. 6 Berthelot. *Rev. mét.* **36**, 357–72(1939).—A comparatively detailed description of the equipment of the plant is given from the standpoint of a fuel technologist. All possible efforts are directed here toward the greatest possible utilization of the heat value of fuel, by treating the process as a whole instead of trying to reach max. economy in individual stages of the manufg. practice disregarding the rest. The plant is able to produce steel from ore with 7 a total expenditure of 1506 kg. of good bituminous coal per ton of rolled steel. J. D. Gat

By-product fuels in the steel industry. Gordon Fox and W. B. Clemmitt. *Iron Steel Engr.* **16**, No. 11, 44–55 (1939).—Characteristics of coke-oven gas and blast-furnace gas and their application in the melting, refining, and heat-treatment of steel are discussed. The principles of mixed gas application are developed. C. B. Jenni

The use of coke breeze in producers. S. Quarfort. 8 *Gas World* **112**, 63–5(1940).—See *C. A.* **33**, 9592[5]. P. J. Wilson, Jr.

Exhaust smoke control in automotive Diesels. W. W. Manville, G. H. Cloud, A. J. Blackwood and W. J. Sweeney. *Natl. Petroleum News* **32**, R-26–30(1940).—The smoking tendency of a fuel is best correlated with the 50% b. p. It is also closely related to the viscosity and gravity. It is more economical slightly to reduce the power than to use a lighter fuel. C. H. Brooks 9

Smoke-consumption in hand-fired furnaces and the use of soft coal. H. Guillon *Chaleur et ind.* **20**, 544–8 (1939).—Preheating the secondary air is suggested and should be more effective with soft than with hard coals, to obtain complete combustion. H. A. Beatty

Indian coals. IV. K. L. Roy, D. Lahiri and B. C. Guha. *Ind. and News Ed. J. Indian Chem. Soc.* **2**, 145–58 (1939); cf. *C. A.* **33**, 5154[8].—Tables give the proximate compn. and decompn. temps. of 16 Indian coals, and classify them as caking, semicaking and noncaking. Values range as follows: moisture 0.46–4.50, volatile matter 16.81–34.60, fixed C 47.09–70.80, ash 8.11–20.97%, B. t. u. per lb. 10,581–12,755, primary decompn. temps. 330–395°. Other data tabulated for some of these coals include elec. cond. of cokes from coals and from coal-pitch mixts., fractionation of pitches by solvent extraction (Cockram and Wheeler, *C. A.* **21**, 2780), coking characteristics of the pitch fractions and of several blends of caking and noncaking coals, effect of pressure during carbonization upon the resulting coke, swelling indexes and heat cond. of powd. coals during carbonization. Coke from noncaking coals has good elec. cond., that from caking coals poor. Coke-pitch blends carbonized at 900° show improved elec. cond. Quality of coke is improved by suitable blending of caking and noncaking coals, by blending noncaking coals with pitch, and by carbonizing under pressure. Heat transmission is more rapid through noncaking than through caking coals. Noncaking coal failed to produce satisfactory coke when carbonized in the presence of volatile matter from caking coal being heated simultaneously. The swelling and caking properties of several coals were completely destroyed by heating 3 hrs. in air at 200–210°; heating 24 hrs. in O-free coal gas, CO_2, H_2, N_2, H_2S, C_2H_2 and at reduced pressure did not change these properties. G. R. Yohe

Hydrogenation of a Pittsburgh seam coal. Kinetics of hydrogen consumption, oxygen removal and liquefaction. H. H. Storch, C. H. Fisher, Abner Eisner and Loyal Clarke. *Ind. Eng. Chem.* **32**, 346–53(1940); cf. *C. A.* **33**, 7074[8].—Coal from the Bureau of Mines exptl. mine at Bruceton, Penna. was hydrogenated in a 1.2-l. bomb. The H consumption *vs.* time curves are straight lines whose slope shows a temp. coeff. of 1.2 per 10°. The diffusion of H through a liquid film surrounding the catalyst surfaces is the factor controlling the rate of H consumption. This is supported by the low-temp. coeff., the approx. const. rate of consumption with varying time and by the lack of dependence of the H consumption rate on the rate of O removal and rate of liquefaction. A study of the O-elimination rates at various temps. shows that the main reaction is a thermal decompn. of the coal substance that results in a rapid elimination of about 60% of the O. This reaction has a high activation energy. The remaining 40% of the O is slowly eliminated by a contact catalytic process with a lower activation energy. At temps. above 400°, the condensation of the liquefied coal substance to form more stable mols. results in apparent neg. temp. coeff. for the second O-elimination reaction. From a study of the rates of liquefaction of the coal at various temps., at least 4 processes are involved: (1) the soln. or extn. of the coal substance which occurs below 370°, (2) a thermal decompn. of the coal substance above 370°, (3) the production of hydrocarbon gases probably by destructive catalytic hydrogenation of the dissolved coal in the range 370–415° and mainly by thermal decompn. of dissolved coal above 415° and (4) the condensation of dissolved coal substance to form mols. more stable than the original coal. These mols. subsequently lose H largely by CH_4 formation. Above 440°, this process results in coke formation even in the presence of 180 atm. of H. Joseph H. Wells

Coal carbonization. Gas pressures within the uncarbonized part of a charge. D. A. Reynolds and G. W. Birge. *Ind. Eng. Chem.* **32**, 363–7(1940).—The gas pressures which develop within the uncarbonized part of a charge of coal carbonized in cylindrical steel retorts increase irregularly as the plastic coal layer moves to the middle of the retort and reach a max. at the time the innermost coal attains the plastic state. For the coals investigated, max. pressures vary according to the rank of the coal, increasing with decrease in the volatile content. The max. pressure obtainable in carbonization of low-

volatile coals is not greatly modified by the temp. of carbonization, provided the heating rate is rapid enough to ensure a continuous plastic layer. Max. pressures developed on carbonizing medium and low-volatile coals decrease as the temp. of carbonization is increased.
Joseph H. Wells

Report of the association on low-temperature carbonization of coal. H. Weittenhiller. *Glückauf* **75**, 741–50(1939).—The association began, in 1935, to investigate various processes for low-temp. carbonization of Ruhr coals in an attempt to increase the yield of Diesel fuel at a lower cost. Numerous ovens were set up but discarded as too expensive to operate. The Berg process carbonized the coal in trays and produced excellent coke and high yield of tar acid from the tar but too low a content of fuel oil. A new Lurgi oven was built, based on studies in the lab., but is not yet in operation. To produce ideal low-temp. coke it was found necessary partially to destroy the swelling property and reduce the coking tendency by means of controlled thermal treatment of the coal. The coal was heated to about 260° for 2 or 3 hrs. depending upon its characteristics before carbonization.
L. P. Rockenbach

The expansion of coal [during carbonization]. Karl Bunte and Hans Imhof. *Gas- u. Wasserfach* **82**, 805–12 (1939).—*Swelling* (Blähen) of coal is defined as the phenomena observed when a molten coking coal is allowed to expand without restriction, as in a crucible or horizontal retort, while *expansion* (Treiben) refers to the phenomena occurring in a completely filled chamber—pressure is exerted on the walls of the carbonizing chamber. A special apparatus, somewhat similar to the Körten-Damm, (*C. A.* **23**, 1495[1]) was devised to follow *expansion pressure* and swelling. A steel plunger with a cross-sectional area of 10 sq. mm. rested on 5 g. of powdered coal in a steel cylinder surrounded by a copper cylinder to insure uniform temperature. Weights were adjusted on a lever arm to keep the plunger level constant within ±0.025 mm. The heating rate was 3° per minute. Swelling tests were made in the same apparatus, with the piston unloaded and free to move. Tests were made on 14 German coals, grouped as follows: (1) noncoking sintering (agglomerating?) coals; (2) nonexpanding coking coals; (3) expanding, coking coals; and (4) two coals intermediate between (1) and (2). Analyses, swelling curves, expansion pressure curves, Foxwell softening curves, and gasification curves are given for each of the coals. The expansion pressure curve is only slightly influenced by particle size but the swelling is much greater with larger particle size, presumably because of oxidation of the fine coal. All coking coals showed appreciable pressures between about 100° and 400°, the pressure required for constant depth varying from 1.5 to 5 kg. over the whole plunger surface; maximum values were given at around 320 to 350°. A second weaker pressure rise occurred at the moment when the Foxwell softening curve began and extended for about 20°; this is apparently due to gas evolution. A few coals also showed a relatively weak third pressure rise, owing to solidification of the melt. Nonexpanding and expanding coals give similar curves, except that pressures are higher for the latter and nonexpanding coals show only slight pressures above 400°. Swelling is attributed to the coal fraction extractible by pyridine, chloroform, or benzene, and swelling and expansion pressure curves are given for the pyridine and chloroform extract from three coals. When a coal is allowed to swell for ten days in an atmosphere of pyridine, it completely loses its expansion pressure. The addition of inert material reduces the expansion pressure greatly; 15% of powdered coke reduces the expansion pressure to 1/3. The addition of 1% boric acid increased both expansion pressure and swelling, contrary to statements in the literature (*C. A.* **27**, 1735). Preheating in a nitrogen atmosphere up to 400° had no appreciable effect on the expansion pressure, and heating to temperatures above 400° had a much stronger influence on swelling than on expansion pressure. On heating in air, the expansion pressure was strongly reduced at 150°, while heating at 250° was required to reduce swelling appreciably. Whether a coal swells or not during plant-scale carbonization depends in part on how much the coal is compressed prior to carbonization and also on whether the coke shrinks enough to offset the swelling encountered with all coking coals. This test is not intended to distinguish between expanding and nonexpanding coals or to replace the usual test apparatus, but is intended to give a clear picture of the phenomena involved. The expression "expansion" should be used to refer to the final end product of volume increase due to swelling, volume decrease due to packing of coal and volume decrease due to coke shrinkage—any practical expansion test apparatus should give this final value.
R. W. Ryan

Recent anthracite research. D. J. W. Kreulen. *Chem. Weekblad* **36**, 870–81(1939).—Anthracite research on the relation between combustion phenomena and certain phys. and chem. consts., undertaken from 1926 to 1932, is reviewed, and the results of chem. analysis, heat of combustion, sp. gr., etc., of wood, peat, soft coal and anthracite are given in a table. The classification of coal on the basis of its content of volatile substances and caloric value is discussed, as is its activity, which in turn depends on its constitution (Fischer). Oxidation of the humus substances into humic acids ($KMnO_4$ method) is outlined, with a detailed reproduction of the calcns. leading to the conclusion that the combustion heat runs parallel with Q, i. e., the sum of the activation energy of the reaction anthracite + O_2 → intermediate stage and the activation energy of the reaction intermediate stage + O_2 → humic acids. This explains the success of American and British anthracite classifications on the basis of combustion heat.
A. H. Krappe

Coal metamorphism in the Anthracite and Crested Butte quadrangles, Colorado. E. C. Dapples. *Econ. Geol.* **35**, 109(1940); cf. *C. A.* **33**, 6023[6].—A correction. M. F.

The assessment of coals liable to damage oven walls. R. A. Mott and C. E. Spooner. *Fuel* **18**, 329–44, 371–9 (1939).—Recent investigations are reviewed. According to M. and S. the shrinkage of coke varies in proportion to the volatile content of the coal; shrinkage is therefore a greater factor in the development of unsafe pressures during carbonization than is the swelling of the plastic coal. They disagree with Auvil, *et al.* (*C. A.* **33**, 9598[3]) who hold that cokes from coals of different rank shrink approx. equally and therefore that the magnitude of swelling depends largely upon the swelling of the plastic coal. The Sheffield lab. coking test (*C. A.* **31**, 2787[7]) and the Koppers small-scale swelling test were used to measure the swelling of 40 coals. The latter test was modified to increase: (1) the heating rate at the bottom of the charge from 6.7 to 33.0° per min., (2) the max. temp. at the bottom from 600 to 940° and at the top from 400 to 750°. As this rapid heating caused excessive swelling of very fluid coals unless fine sizes were excluded, only the 10–20-mesh size was tested. The bulk d. of the 80-g. charges was 750 kg. per cu. m. (46.8 lb. per cu. ft.); pressures of 0.5 and 1.16 kg. per sq. cm. were maintained. Three of the coals were known to swell dangerously in com. ovens. Nine were also tested by the Nedilmann app. (*C. A.* **25**, 1656), 11 by the Baum-Heuser test (*C. A.* **25**, 2833), and 5 by the Koppers large-scale test (*C. A.* **25**, 5752). Results for the Bureau of Mines sole-heated and slot oven test methods were available for 4 coals. The use of fine sizes of coal gives incorrect results with the Nedilmann test but not with the Baum-Heuser. Conclusions: (1) Small-scale lab. tests afford a satisfactory measure of the liability of coals to damage oven walls. (2) In all tests the app. and procedure must be standardized. (3) A min. temp. of 900° must be reached. (4) Unsafe coals can be assessed either by detg. the swelling pressure or the percentage swelling. The latter should be supplemented by the percentage contraction. The modified Koppers test permits the detn. of contraction under standard load and is therefore the most serviceable. (5) In lab. tests contraction of the coke is more significant than swelling of the coal. (6) Tests of each coal should be made with charge d. of 700, 750 and 800 kg. per cu. m. and the 3 contractions should fall on a straight line of

specified slope. (7) Coals of 25% volatile content (Parr basis) are unlikely to be unsafe at a charge d. of 750 kg. cu. m. (46.8 lb. per cu. ft.) calcd. to dry coal. For higher bulk d. the limiting volatile matter at which coal ceases to be unsafe is higher. (8) Dangerous coals which cannot be coked alone have 17.0 to 25.5% volatile matter and a calorific value above 15,750 B. t. u. per lb. D. A. R.

Practical results in the choice of coal and coal mixtures for improving high-temperature coke. F. L. Kühlwein and C. Abramski. *Glückauf* 75, 865–74, 881–90(1939).—A very thorough review of the improvements in the high-temp. coking of coal in Germany. Modern practice is selective washing, then mixing instead of the old method of first mixing coals and then cleaning them. Blending substances employed to reduce the volatile content of high-volatile coals and improve the coke strength are: (1) low-volatile coals from other fields, (2) storage coal whose coking properties have been reduced by oxidation, (3) thermally treated or preoxidized coal, (4) noncoking gas coal, (5) durain, (6) fusain, (7) coke breeze. Expts. have shown that low-volatile coals ground to 2-mm. fineness produce the strongest cokes. Larger-size particles reduce the coke strength in the tumbler tests. The addn. of 5% coal dust to 65% high-volatile coal and 30% low-volatile coal produces a coke of 83% hardness (tumbler test) as compared to 71% for a coke made from high-volatile coal alone. L. P. Rockenbach

Recovery of sulfur in coal-carbonization plants and petroleum refineries. Ch. Berthelot. *Génie civil* 116, 6–7(1940); cf. *C. A.* 33, 8188.—Current methods of obtaining S from gas from cracking plants and coke ovens are described, particularly the Shell and Kopper processes and that used at Renory. Germany might obtain 1/4 of her normal S requirements in that way. A. N. H.

Fusibility of coal ash. IX. Fluxing effects of lime, silica and some basic constituents upon coal ash. Y. Kosaka and H. Toda. *J. Soc. Chem. Ind., Japan* 42, Suppl. binding 332–4(1939); cf. *C. A.* 31, 6850³.—CaO, added to coal ash, rapidly lowers the softening point of the ash when present in amts. up to 10–12%; further addn. of CaO has little or no effect. Increase of the SiO_2/Al_2O_3 ratio above 2.5 (for definite CaO contents) has little effect on the softening point. In order to flux a refractive Japanese coal ash, it is desirable to build the compn. of the ash to a ratio such as $SiO_2:Al_2O_3:CaO = 42:20:38$ (which represents one of the eutectic mixts.), by adding CaO and (or) SiO_2. $CaSO_4$ as a flux is only approx. as efficient as its equiv. in CaO. MgO is a more effective flux than CaO, while alkalies, calcd. upon the basis of K_2O or Na_2O, have an extremely high fluxing power, the effect being large for the first 5% present. However, alkalies are not recommended on account of their corrosive action upon the furnace brick. **X. Relation between the chemical composition and the fusibility of coal ashes.** *Ibid.* 334–6.—By use of the equation $S = S_0 - nb$, where S = softening point of the ash, S_0 = fusion temp. of a pure SiO_2–Al_2O_3 system (Bowen and Greig, *C. A.* 18, 2587) of the same ratio as in the ash, n = fluxing index of the ash, and b = percentage of CaO, MgO, Fe_2O_3, and alkalies (the percentage of Fe_2O_3 should be low), the softening point of Japanese coal ashes can be calcd. usually within ±50°. The value of n decreases with increase in b; for each value of SiO_2/Al_2O_3 n can be plotted against b, giving a smooth curve except when a considerable amt. of Fe_2O_3 is present. The value of b increases with increase in the SiO_2/Al_2O_3 ratio. George Ayers

Reconnaissance at Alloa gas works. Athol W. Brown. *Gas J.* 229, 247–8(1940).—The *electro-detarrer* installed on the plant is designed for tar-fog removal from a max. of two million cu. ft. of gas per day. The av. of the tests during a month's operation showed 0.4 grain of tar per 100 cu. ft. in the outlet gas, equiv. to a removal efficiency of 99.7%. The *org. S* in the gas is reduced from 8.3 grains per 100 cu. ft. down to 4.07 grains by scrubbing with 4 gal. of wash oil per 1000 cu. ft. of gas. P. J. Wilson, Jr.

Fuel gas. Vehicles for compressed gas. P. Larivière. *Chaleur et ind.* 20, 541–2(1939); cf. *C. A.* 33, 8958⁸.—Vehicular gas holders are described. H. A. Beatty

Substituting butane and propane for manufactured gas. A. C. Rathkey. *Gas Age* 85, No. 3, 22–4(1940).—The successful changeover from small gas plants to the use of compressed butane or propane is outlined. Such plants cost $10,000 to $25,000, may operate without reserve equipment, effect savings of 5% to 30% in gas production costs, diminish meter and regulator troubles, decrease naphthalene and tar stoppages, and eliminate pilot difficulties. The liquid is stenched with EtSH at the refinery. The changeover costs about $5 per customer. Leaks with the new gas are harder to locate than when carburetted water gas is used. Relative merits of C_4H_{10} and C_3H_8, of gas mixts. whose B. t. u. values vary from about 900 to 500, of dew points and seasonal variations in gas compn., etc., are discussed. W. C. Ebaugh

Effects of cyanogen on manufactured gas. E. J. Murphy. *Gas Age* 84, No. 11, 23–7(1939); *Am. Gas J.* 151, No. 6, 9–13, 41(1940).—Prussian blue is an end product of corrosion of Fe by HCN. A ferrous condition and H_2O are required before HCN is fixed. Stoppages of Cu needle valves are caused by a corrosion product composed of Cu, mercaptans and HCN. Fe produced similar results but slower. Al gave no deposits. Various forms of org. S were bubbled with HCN through Cu tubing and the following relative reaction rates obtained: Et mercaptan 100, diethyl sulfide 40, phenyl mercaptan 11.1, diphenyl sulfide 4.7 and CS_2 3.9. In all cases, the reaction product gave a pos. reaction with Griess reagent. Liquid purification systems remove more than 90% of the cyanogen and the remainder is removed by dry purifiers as catch boxes. Dry purification systems can be made to absorb cyanogen by controlling the moisture, O and alky. of the boxes. Two grains of HCN per 100 cu. ft. may be present in the gas provided there are no mercaptans present but in the presence of mercaptans gas with 0.4 grain of HCN is sufficient to create corrosion stoppages on brass needle valves. A modified isopurpuric acid method for detg. HCN in gas is described. J. H. W.

Improvement in the calorific value of town gas or coke-oven gas with reference to utilization as a fuel for motor vehicles. J. Ivon Graham and D. G. Skinner. *J. Inst. Fuel* 13, 39–43(1939); *Gas World* 112, No. 2896 Coking Sect., 13–19; *Gas. J.* 229, 39–41(1940).—By use of active charcoal the hydrocarbons in town gas were increased from about 20% by vol. up to 44.5%, expressed as CH_4. The CO was also concd. from 16 up to 27%. Since increase in the CO limited the concn. of hydrocarbons which could be attained, the catalytic conversion of CO to CH_4 in accordance with the equation, $CO + 3H_2 = CH_4 + 2H_2O$, was studied. Ni supported on charcoal made from sugar with the addn. of 1% Ce nitrate as promoter proved to be the most efficient catalyst tested. Gas contg. 17% CO and 20% CH_4 was passed at the rate of 6.6 l. per hr. through 1.5 cm. diam. tubes contg. 20 g. of catalyst (6 g. Ni). After 20 days continuous operation CO in the gas from the tubes was 1.6% and the CH_4 was 63%. Road tests of the product as fuel in a 12 h. p., 4-cylinder, Austin truck showed a consumption of 13.2 cu. ft. per mile. The waste gases contained practically no CO. Enrichment of town gas for use in motor vehicles will not easily show a saving unless consideration is taken of the increased mileage to be obtained for a given storage cylinder wt. By mixing blue water gas with town gas in the proportion of 1:5 the cost of the fuel should be much reduced. P. J. Wilson, Jr.

Locating (natural gas) pipe-line leaks with odorant. L. Millis. *Gas* 16, No. 2, 30–1(1940).—A by-pass odor was used to introduce Pentalarm odorant into the natural gas system at the rate of 15 lb. per million cu. ft. This permitted the pipe-line walker to identify leaks along the line without using bar holes or uncovering an excessive amt. of pipe. Recently, good results have been secured with half this amt. of odorant. The odor diminishes on long lines so that more than one odorizer may be required. R. W. Ryan

Thermal alkylation and neohexane. I. G. Oberfell

and F. E. Frey. *Oil Gas J.* **38**, No. 28, 50, 51; No. 29, 70, 73, 74, 76(1939).—See *C. A.* **34**, 1151[9]. W. A. W.

Investigation of the procedure in the distillation of benzene. C. Koeppel. *Glückauf* **75**, 465–74(1939).—The customary dephlegmator used in recovering benzene from wash oil has been replaced by a simple arrangement of 2 stills connected by means of a reflux pump. Curves showing the influence of oil temp. and quantity and quality of the steam used on the benzene content of the distillate are given. Dry superheated steam at 330° and 8 atm. is superior to satd. steam. Lab. studies with vacuum distn. of wash oil show that above 190° considerable cracking of the wash oil results with the formation of lower-boiling hydrocarbons. Strong preheating of the wash oil increases the H_2S content in the crude benzene with a resp. decrease in the wash oil. L. P. Rockenbach

Blaw-Knox cleaner installation at Rutland, Vt. S. F. McCallister. *Gas Age* **84**, No. 11, 21–2, 34, 36(1939).—The Blaw-Knox cleaner is a liquid scrubber in which the gas is washed with oil. It is a satisfactory device for the removal of tar fog, oil vapors, excess H_2O and $C_{10}H_8$. It is believed that it will remove practically all of the liquid-phase gum formers. Joseph H. Wells

Burnt oxide for hydrogen sulfide removal. G. E. Thompson. *Gas J.* **229**, 190(1940).—Burnt oxide from a H_2SO_4 plant was used for removal of H_2S from town gas with reasonably satisfactory results. The gas was passed through oxide equiv. to a column about 18 ft. high at the rate of 17,000 cu. ft. per day per sq. ft. of initial surface, and gave a clean test from the final box. The oxide was worked to 40 to 50% S before returning to the acid plant. Analyses of oxide before and after fouling are given. P. J. Wilson, Jr.

Determination of naphthalene in (bituminous) gas oil. N. F. Alekseev. *Zavodskaya Lab.* **8**, 1073–8(1939).—The detn. of naphthalene in the oil from bituminous coal as picrate gives good results. Difficulties arise when the oil contains constituents which form nonvolatile picrates. The volatile unsatd. compds. and the homologs of $C_{10}H_8$ can be removed by polymerizing with H_3PO_4 or by oxidizing with $KMnO_4$, since the volatile compds. are oxidized in the cold and the $C_{10}H_8$ is oxidized when heated. The accurate addn. of the $KMnO_4$ is difficult. Hence, 3–5 detns. are made with $KMnO_4$ addns. varying from 3 to 10 ml. The results are plotted showing no. of cc. $KMnO_4$ *vs.* percentage of $C_{10}H_8$. The curve has a distinct break at a point which corresponds to the actual $C_{10}H_8$. The sample is treated with various adsorbents to remove the volatile compds. after which the $C_{10}H_8$ can be detd. as a picrate. Best adsorbents were found to be alumina and sugar. B. Z. Kamich

Solvent action of liquid propane on the pentane-soluble fraction of a high-temperature bituminous coal tar. C. S. Kuhn, Jr. *Ind. Eng. Chem., Anal. Ed.* **12**, 86–9(1940).—The liquid phases formed by the action of liquid C_4H_{10} on the C_5H_{12}-sol. fraction of a high-temp. bituminous coal tar were studied. The ext. increases in d., n and mol. wt. and decreases in H/C ratio as the ratio of C_4H_{10} to tar is increased. The sepn. is largely on the basis of mol. wt. In general there is a tendency for O, N and S compds. to concentrate in the residue. Henri Marc

Tar carpets. G. H. Fuidge. *Gas J.* **229**, 187–9(1940).—The tar carpets that have been manufd. and laid commercially can be divided into types, designated as open carpets, coarse- and medium-texture carpets, fine-texture carpets, and hot-process carpets, resp. Compns. and characteristics of the types are given. Methods for control of tar-carpet manuf. are described. P. J. W., Jr.

Materials for the production of exhaust pipes for gases from coke ovens. V. P. Ivanov and B. M. Idel'chik. *Korroziya* **4**, No. 3, 241–7(1938); *Khim. Referat. Zhur.* **2**, No. 4, 142(1939).—The stability in coke gas of the following alloys was investigated: "commercial" latten, Ni latten, bronze "bazhm," 5 and 10% Al bronze, various steels, sheet Al and rolled Pb. Exposure to coke gas, purified from the tar, for 720 hrs. at 50–160°, caused all samples to be covered with films, but their loss of wt. was insignificant. Latten was found to be the most suitable material. W. R. Henn

The coke "content" and volatile matter in solid combustibles. Henri Cassan. *Chaleur et ind.* **20**, 526(1939).—Radmacher's use (*C. A.* **33**, 6019[8]) of the term, "content," is criticized. H. A. Beatty

Corrosion survey—a field study of the corrosion resulting from the combustion of fuel gases. John H. Bosbyshell and Jesse S. Yeaw. *Am. Gas J.* **151**, No. 6, 28–33(1939).—A survey has been conducted in several territories to evaluate the relative effects of the fuel gases distributed in those territories. The combustion chambers and flue conduits on domestic equipment, particularly Electrolux refrigerators, house-heating units, and water heaters, were inspected, and the effects of corrosion were evaluated by means of a prearranged corrosion scale. The results indicated that condensation of the products of combustion of gas contg. S resulted in corrosion of the combustion chambers and flue pipes. S must be reduced considerably below 2 grains per 100 cu. ft. to eliminate corrosion problems. Other constituents of the gas did not appear to be significant with respect to corrosion. The problem of a proper material for either flue pipes or chimney linings, except where the chimney was correctly tile-lined when constructed, has not been solved. P. J. Wilson, Jr.

Corrosion at coke plants. Hans Bockshammer. *Glückauf* **75**, 786–7(1939).—A deposit of tar on the walls of the pipe is usually sufficient protection against corrosion. Recent use of Zn has replaced Pb in plating iron in the ammonia plants. Hard rubber is also used effectively for coating iron wherever H_2SO_4 is present. L. P. R.

Complex process for treating Fe ore contg. P and phosphorite [gases from process can be used for fuel] (Malets) 9. Flue-gas explosions (Matthews) **24**. Causes of tar-distn. explosion (Riehm) **24**. Device for removing paraffin from gas wells (U. S. pat. 2,182,931) 22.

Eavenson, Howard N.: Coal through the Ages. 2nd ed. New York: American Institute of Mining and Metallurgical Engineers. 123 pp.

Fuel. Hubert Williams and Norman Frederick Bette-Bennett. Brit 508,000, June 26, 1939. Coal, coke breeze or anthracite is pulverized to a fine powder, oil and then H_2O and NaCl are mixed therewith and shellac or asphalt in a liquid or powder form is sprayed on the mixt. which is then thoroughly mixed and compressed to form logs or blocks. In Brit. 508,053, June 26, 1939, the blocks, etc., are wrapped in a covering of waxed paper, glacé paper, etc.

Motor fuel. Ernest M. Marks (to Atlantic Refining Co.). U. S. 2,181,143, Nov. 28. A method of increasing the antidetonation characteristics of gasoline comprises adding to the gasoline an oxidation product of triisobutylene boiling within the boiling range of gasoline and resulting from the oxidation of triisobutylene under conditions such that the ratio of O to triisobutylene is at least mol for mol.

Retort suitable for destructive distillation of wood, coal, etc. Frederick Pope (to American Cyanamid Co.). U. S. 2,182,750, Dec. 5. Various structural and operative details.

Apparatus for carbonizing fuel briquets, etc. Eric C. Mengel (to Humphreys & Glasgow Ltd.). U. S. 2,181,789, Nov. 28. Various structural and operative details of app. for carbonizing by a circulated heated gas.

Apparatus for producing fuel gas by vaporizing volatile hydrocarbons. W. M. Venable (to Blaw-Knox Co.). U. S. 2,182,684, Dec. 5. There are used together: a container with its outer surface in heat-exchange contact with the earth, a reservoir for liquid within the container, a connection between the reservoir and container permitting the passage of liquid from the reservoir but preventing its return, a gas outlet, and an elec. heater within the reservoir adapted to establish a higher temp. and conse-

quent higher gas pressure within the reservoir than in the container.

Use of iron oxide in gas purification. Claude W. Jordan (to United Gas Improvement Co.). U. S. 2,181,433, Nov. 28. Fe oxide which has become dehydrated in a dry purification as a result of passing dry manufd. gas through it is brought into contact with water in the presence of an org. wetting agent such as a "Gardinol," "Avirol" or "Igepon A."

Apparatus for operating coke-oven doors. Paul H. Lavely (to Koppers Co.). U. S. 2,182,494, Dec. 5. Various structural, mech. and operative details.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER AND STEWART S. KURTZ, JR.

Annual Reviews of Petroleum Technology, Vol. 4, covering 1938. F. H. Garner, General Editor. Published by Inst. of Petroleum (1939). Price 11s. 0d. 478 pp.—A series of reviews, as follows: **Petroleum geology.** A. I. Levorsen. **Regional geology and development in the U. S.** W. A. Ver Wiebe. **Regional geology—all countries other than the U. S. A.** G. D. Hobson. **Geophysics.** H. Shaw. **Drilling.** H. W. Hole. **Production engineering.** G. H. Scott. **Production.** L. W. Storms, Jr., and T. A. Huber. **Transportation and storage.** A. C. Hartley. **Refinery plant and engineering.** W. J. Sweeney and E. D. Reeves. **Cracking.** P. C. Keith, Jr., C. W. Nofsinger and J. V. Hightower. **Pyrolysis and polymerization.** D. A. Howes. **Natural gas, natural gasoline and liquefied petroleum gases.** Thelma Hoffman. **Gasoline, white spirit and kerosene (light distillates).** G. R. Nixon. **Diesel and gas oils.** R. F. Brown

Chemistry of petroleum of Murinsel (Drave-Banat). S. Jenčič. *Rudarski Zbornik* [2], **1**, 12 27(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1938**, 728.—The crude oil from Selnica is a light (d. 0.851) paraffin-naphthene-aromatic oil with predominant paraffin-naphthene characteristics: fractionation gives (by vol.): below 200° 24%, 200-300° 39.5%, 300-360° 23.5%, paraffin 4.8%, hard asphalt 0.03%, petroleum resin 3.5%. That from Peklenica is a heavy (d. 0.927) naphthene-aromatic oil giving (by vol.): below 200° 0.5%, 200-300° 23%, 300-360° 15%, paraffin 1.6%, hard asphalt 0.3%, petroleum resin about 14%. 6 C. A. Silberrad

Goldsmith field, Ector County, Texas. Addison Young, Max David and E. A. Wahlstrom. *Bull. Am. Assoc. Petroleum Geol.* **23**, 1525-52(1939).—The oil and gas reservoir is a porous zone. Porosity has been developed by subaerial erosion and soln. Oil, gas and water analyses are given. Alden H. Emery

The use of density-increasing substances and of reagents in the preparation of drilling mud. E. A. Yaichnikova. *Azerbaĭdzhanskoe Neftyanoe Khoz.* **1938**, No. 10, 30-3; *Khim. Referat. Zhur.* 2, No. 4, 116(1939).—To replace $BaSO_4$ for increasing the d. of drilling muds the residues of H_2SO_4 production of the Baku and the Konstantinov plants and hematite from Krivoĭ Rog were used. Pos. results were obtained in both cases. The residues, having a sp. gr. of 3.83, increased the d. of the muds only to 1.8. A large amt. of the reagents and of water was needed which increased the vol. of the mud by almost 100%. An increase of the d. of the muds with hematite was most effective. The results obtained must be verified under production conditions. W. R. Henn

Crude oil found in Romny and other petroleum-bearing districts of the Russian Ukraine. A. G. Shlikhter. *Trudy Neftyanoĭ Konf. Kiev, 1938, Akad. Nauk U. S. S. R. (Inst. Geol. Nauk)* **1939**, 7-12.—Crude oil was found at a depth of 256.79-276.12, 328.05-348.15 and 367.0-378.0 m. The third layer was the richest in oil, which contained gasoline 2, kerosene 28, oils 60 and residue 10%. A. A. Boehtlingk

New way of determining the porosity of oil-bearing strata. E. J. A. Cosijn. *Bohrtech.-Ztg.* **56**, 1-3(1938); *Neues Jahrb. Mineral. Geol.*, Ref. II, **1938**, 709-10.—The new "gas-expansion" method is described in which the porosity is detd. by deducting the volume of solid matter in a known vol. of the material as detd. in a pressure chamber. C. A. Silberrad

Equipment inspection for greater refinery safety. P. N. Gammelgard. *Refiner Natural Gasoline Mfr.* **19**, 8-15 (1940).—The several causes of equipment failures of properly operated units are discussed, with specific examples. Proper inspection technique and inspection records, both of which are outlined, will do much to prevent such failures. C. H. Brooks

Seals for air-tight connections in oil refineries. J. Colson. *Bull. assoc. franç. techniciens pétrole* No. **47**, 88-105(1939).—The advantages and disadvantages of synthetic rubbers of the chloroprene and butadiene type in making air-tight seals in refinery connections are discussed as well as the merits of vinyl and amyl resins, cellulose ethers, and phenolic and aminated resins. E. J. M.

Field lining of refinery vessels with stainless steel sheets or strips. K. E. Luger. *Refiner Natural Gasoline Mfr.* **19**, 41-6(1940).—A thorough discussion of the technique of installing thin stainless steel, as linings, in the field. C. H. Brooks

Electrical engineering and the petroleum refiner. G. R. Weeks, H. W. Giesecke and C. M. Lathrop. *Elec. Eng.* **59**, Tr. 106-10(1940).—Oil-refinery design and operation have been affected by recent developments in elec. engineering. The subject is discussed under the following topics: safety precautions, steam and compressed air, motor control, instruments, welding and lighting. C. G. F.

Significance of viscosity in the use of petroleum oils. W. L. Nelson. *Oil Gas J.* **38**, No. 28, 46(1939).—A review concerning viscosity effects in the automotive engine, such as pumpability, power consumption and wear. W. Andrew Wright

Alkylation and its influence on the unitization of natural gasoline. Earle W. Gard, A. L. Blount and Karl Korpi. *Oil Gas J.* **38**, No. 31, 42, 43, 51, 65, 67; No. 32, 46-8; *Refiner Natural Gasoline Mfr.* **18**, 525-32(1939).—Graphical data on the effects of temp. and isobutane concn. on yields with the H_2SO_4 process for alkylation to natural gasoline. Typical fractionation data for the product and flowsheets are given. W. Andrew Wright

Catalytic cracking. Arch L. Foster. *Refiner Natural Gasoline Mfr.* **18**, 412-18(1939).—A lengthy discussion of the present state of the art. C. H. Brooks

Vapor-phase purification of cracked gasoline with clay. P. T. Sverbil. *Rabochiĭ Neftyanik* **1938**, No. 6, 15-18; *Khim. Referat. Zhur.* 2, No. 4, 117(1939).—Expts. performed in the Odessa cracking plant showed that the vapor-phase purification of cracked gasolines with Zikeev clay according to the method of Gray was much more profitable than the purification with H_2SO_4. Losses of gasoline were reduced and the technology of the method was much simpler. Instead of alkali for washing the gasoline (to improve the Cu strip test) the Odessa plant successfully used sea water. More stable gasolines for storing were obtained. W. R. Henn

Chemical composition of synthetic gasolines. A. N. Sachanen. *Refiner Natural Gasoline Mfr.* **18**, 521–4 (1939).—The available methods of chem. analysis of gasolines are discussed. Data on the content of aromatic compds., unsatd. compds., naphthenes and paraffins in 19 synthetic gasolines are presented. 13 references. C. H. Brooks 1

Surge-voltage breakdown characteristics for electrical gaps in oil. Royal W. Sorensen. *Elec. Eng.* **59**, Tr. 78–84 (1940).—Surge breakdown voltage readings were made for different gap spacings with 0.25, 0.5 and 1.0 in. round rod electrodes immersed in transformer oil. The values are a function of "time to breakdown." Details are given of a special type of test barrel used, requiring a relatively small sample of oil. The lead-in bushings are made of insulation material having about the same dielec. const. as the oil to be tested. C. G. F. 2

Fuel-oil combustion diagrams. Brunet. *Bull. assoc. franç. techniciens pétrole* No. 50, 37–71(1939).—Fuel-oil combustion diagrams based on the fuel diagrams of Grebel and the combustion diagrams of Ostwald were detd. for the following cases of combustion: complete neutral combustion, complete oxidizing combustion, incomplete combustion without excess air, combustion with a const. excess or deficiency of air, combustion with const. percentage of CO, incomplete combustion in a reducing atm. of CO alone, and, incomplete combustion in a reducing atm. of CO and H_2. E. J. M. 3

Evolution of selective solvent extraction process. Rene Navarre. *Bull. assoc. franç. techniciens pétrole* No. 46, 19–55(1938).—See *C. A.* **33**, 3648. E. J. M. 4

Catalytic dehydrogenation process (gaseous paraffins to olefins). A. V. Grosse, V. N. Ipatieff, Gustav Egloff and J. C. Morrell. *Oil Gas J.* **38**, No. 28, 53, 55(1939).—The production of isoöctane from *n*-butane by catalytic cracking followed by polymerization and hydrogenation is discussed. Operating data and flowsheets are given. W. Andrew Wright 5

New method of examining lubricating oils. P. Lecomte du Noüy. *Compt. rend.* **210**, 101–2(1939).—A H_2O surface is touched with a glass rod smeared with the oil to be examd. and the consequent fall in surface tension (S. T.)—usually 6–12 dynes—noted. It remains practically const. The oily surface is then touched with another rod similarly carrying a trace of oleic acid. This causes a much larger (15–20 dynes) fall in S. T., which, however, slowly disappears in 2–3 hrs., to an extent depending on the nature and quality of the oil. With an oil such as paraffin oil contg. no polar groups (a poor lubricator) the recovery is only 3–5 dynes, but with a good lubricating motor oil it amounts to 15–20 dynes. If tallow is used in place of oleic acid the recovery takes 11–12 hrs. The effect is probably due to adsorption of the polar mols. of oleic acid by the oil. If the motor oil be filtered through 4 sheets of filter paper the recovery is reduced to 3–4 dynes like the paraffin oil (cf. *C. A.* **30**, 6544[6]), which the oil then resembles in other respects. C. A. Silberrad 6

Some remarks regarding the testing of engine lubricants. C. A. Bouman. *J. Inst. Petroleum* **25**, 771–8(1939).—Oxidation tests do not represent the various processes of deterioration taking place in the engine. Deterioration of engine oil is often a matter of contamination with combustion products. C tests are only of value with regard to C formation in the combuston space but not with regard to C formation in piston-ring grooves or to the tendency to stick rings. Engine tests are necessary but a large no. of tests are required to reach a conclusion. The test conditions must be chosen so as to give a good correlation with those conditions in practice for which an oil is intended. Joseph H. Wells 7

Extreme-pressure lubricant tests with pretreated test-pieces. J. P. Baxter, C. I. Snow and I. T. Pierce. *J. Inst. Petroleum* **25**, 761–70(1939).—Expts. with the Timken and Four-Ball lubricant testing machines are described in which considerable increases in the breakdown loads of doped and undoped oils were obtained by pretreatment of the test pieces with chlorinated or sulfurized dope or with HCl. Running-in tests showed that the layer so formed was not removed by running under loads below the breakdown load. The pretreatment of the Cornell test pieces had no apparent effect, but when these were hardened to a value comparable with that of the other machines, the breakdown loads become too high for the machine to measure. Joseph H. Wells 8

Electrophysical properties of transformer oils at low temperatures. A. A. Vorob'ev and N. A. Prikhod'ko. *J. Tech. Phys.* (U. S. S. R.) **9**, 1369–76(1939).—The sp. gr. of several transformer oils is a linear function of temp. Their viscosity below −20° is mainly structure viscosity. Below −20° elec. field of 4 kv./cm. increases the η. On cooling from room temp. the breakdown voltage sharply rises at 0° owing to sepn. of ice; it gradually rises again below −25°. J. J. Bikerman 9

An analytical method used in the study of the composition of asphalts and cracked fuels. E. S. Hillman and B. Barnett. *Refiner Natural Gasoline Mfr.* **18**, 533–8(1939).—From 10 to 20 g. of sample is dild. 40-fold with isopentane. The insol. material is successively extd. in a Soxhlet with iso-C_6H_{12}, C_6H_{14}, mixts. of C_6H_{14}-CCl_4, pure CCl_4, C_6H_6, CS_2 and pyridine. Mixts. of C_6H_{14}-CCl_4 are necessary to remove dispersing agents from the more refractory materials. Reproducibility is within ±5%. The proportions of cracked and straight-run fuels in a blend can be calcd. within ±6%. C. H. Brooks 10

Asphaltic rocks and the Italian production of liquid fuels. E. Salerni. *Chim. ind. agr. biol.* **15**, 588–97(1939).—The asphaltic or bituminous rocks obtained from deposits occurring in Abruzzi and in Sicily show the following characters, resp.: d_{15} 0.959–0.980, 0.835–0.940; bitumen 2.8–9.2, 6.5–8.0%; oil yield 60–74, 74–75%. The industrial methods and the plants for extn. of the oil, the products of the fractional distn., and the yields and costs are illustrated. G. A. Bravo 11

Naval stores in the Dutch East Indies. Development of a new industry. T. Hedley Barry. *Ind. Chemist* **15**, 409–10, 423(1939). E. H. 12

New solvents from waste products [of wood distillation]. A. N. Revazov. *Lesokhim. Prom.* **1938**, No. 5, 33–4; *Khim. Referat. Zhur.* **2**, No. 4, 131–2(1939).—The waste products of the rectification of crude CH_3OH are dild. with water (1:1) and rectified. The fraction boiling up to 86° (40–50% of the charge) is treated with alkali and rectified. The solvent "M" boils between 76 and 77° and its yield is 20–30% of the initial crude material. It is clear, colorless, sp. gr. 0.841, soly. in water 58% for 1:1 and 85% for 1:4, content of ketones (calcd. to acetone) 41.7%, acidity 0.019% (calcd. to HCOOH) and 95% of the solvent boils at 69–81°. Solvent "M" can also be obtained from the floating alc. oils. W. R. Henn 13

Extraction of methyl alcohol from the products of gasification of wood material. V. I. Kropotov. *Lesokhim. Prom.* **1938**, No. 5, 32–3; *Khim. Referat. Zhur.* **2**, No. 4, 131(1939).—When AcOH is extd. from the generator gases in the form of solns. of Ca acetate powder, the powder condenses a part of the CH_3OH vapors contained in the gas. A further concn. of the solns. in the 3-still evapg. app. liberates the CH_3OH vapors together with water vapors. The concn. of CH_3OH in the condensate of the first still of the evaporator reaches 0.5%. From a further rectification in the lab. a 96.2% CH_3OH was obtained. W. R. Henn 14

Losses of methyl alcohol in the gas-purifying systems of wood-gasifying plants. N. V. Chalov. *Lesokhim. Prom.* **1938**, No. 3 4, 7–11; *Khim. Referat. Zhur.* **2**, No. 4, 131(1939).—The yield of CH_3OH from gasification of wood is 0.6–1.6% of the dry wt. of wood, depending on the kind of wood and on the method of production. The losses of CH_3OH in the elec. purification of the gases depend on the moisture content of the tar, which in turn is a function of the temp. of the gas after the purification. With a normal moisture content of 25% the losses of CH_3OH are 2–2.5% of its content in the gas before the elec. filtration. The losses found in scrubbers on cooling the solns. vary widely (from 3.9 to 56.6%) depending on the temp. of the gas after the scrubber and on the amt. of water 15

which is condensed from cooling. The losses can be reduced to 15–20% by changing the adjustment of the scrubber. If the moisture content of the gas before the salt scrubbers does not exceed 300–20 g./cu. m. the losses can be reduced to 8–15%. A method has been proposed in which AcOH is absorbed from the gas and the losses of alc. reach a max. of 10%, but can be reduced to 4–8% of the content of alc. before the scrubbers. W. R. H.

Geochem. and geol. factors of formation of crude oil (Porfir'ev) 8. Recovery of S in petroleum refineries (Berthelot) 21. Practical considerations on temp. control [in cracking oil] (De Florez) 1. Metals in deep-well drilling (Nelson) 9. Chemistry of waters beneath the Dnepr-Don depression and their connection with size of oil deposits (Makov) 8. Greases in every steel mill (Kolb) 9. Tubes, etc., for use at high temps. in heating fluids such as in cracking oils (U. S. pat. 2,182,177) 9. Polymerizing olefins such as isobutylene from still gases (U. S. pat. 2,182,512) 13. Petroleum Products. New York: The Texas Co. 87 pp.

Conversion of petroleum oil. Gerald L. Eaton (to Gulf Oil Corp.). U. S. 2,182,536, Dec. 5. An arrangement of app. is described, and a process of obtaining gasoline of high antiknock value from petroleum oil; it comprises subjecting a mixt. of petroleum oil and hydrocarbons contg. 3 and 4 C atoms per mol. to cracking in a heated conversion zone, fractionating the vaporous products of conversion to recover gasoline, tar and intermediate condensate, bringing the remaining gases in a first absorber into contact with the petroleum oil, prior to cracking the latter, to recover from the gases the bulk of the hydrocarbons contg. 3 and 4 C atoms per mol. and cracking the resultant mixt. of oil and absorbed hydrocarbons. The gases leaving the first absorber are brought into contact with a portion of the intermediate condensate in a second absorber to absorb substantially all of the propane contained therein, together with some ethane; a second flow of hydrocarbon gases in a third absorber is brought into contact with a further portion of the intermediate condensate to remove hydrocarbons contg. 3 and 4 C atoms per mol. therefrom, the enriched condensate from the second absorber is introduced into the third absorber and ethane is vaporized from the enriched condensate by the heat of absorption in the third absorber. The condensate enriched with hydrocarbons contg. 3 and 4 C atoms per mol. but substantially free of hydrocarbons contg. one or two C atoms per mol. is withdrawn from the third absorber, and recirculated into the cycle at a point intermediate the heated conversion zone and the point of recovery of the intermediate condensate from the products of conversion.

Furnace and tube system suitable for hydrocarbon-oil conversion. Jacob B. Heid (to Universal Oil Products Co.). U. S. 2,182,586, Dec. 5. Various structural and operative details.

Converting hydrocarbon gases (such as olefins from oil cracking) into liquid hydrocarbons. Cary R. Wagner (to Pure Oil Co.). U. S. 2,181,749, Nov. 28. An arrangement of app. is described, and a process of converting hydrocarbon gases contg. approx. 40–60% of olefins into liquid hydrocarbons rich in toluene; the process comprises subjecting the gases in the substantial absence of nonhydrocarbon gas to temps. within the limits of approx. 605–635° and under superatm. pressure below that at which C formation is actively promoted for a time ranging from 5 to 30 sec., cooling the reaction products below reaction temp. and sepg. the liquid from the gaseous reaction products. Cf. *C. A.* 34, 1144.

Converting normally gaseous hydrocarbons such as natural or oil-cracking gases to normally liquid hydrocarbons. Percival C. Keith, Jr., Geo. W. Robinson and Geo. Roberts, Jr. (to Polymerization Process Corp.). U. S. 2,181,302, Nov. 28. A portion of a stream of normally gaseous hydrocarbons is liquefied and sepd. from the unliquefied gases. The gases are scrubbed with a liquid absorbent comprising a substantial proportion of hydrocarbons in the gasoline boiling range. The gases are again scrubbed, in a 2nd zone, with an absorbent consisting essentially of gas oil. The liquefied portion of the stream is heated to effect conversion to normally liquid hydrocarbons. The products of conversion are brought into contact with enriched absorbent media from the 2 scrubbing zones. Normally gaseous hydrocarbons are sepd. from this mixt. and at least a portion of the normally liquid constituents, including a substantial proportion of gasoline constituents, is introduced into the primary scrubbing zone.

Cracking and coking hydrocarbon oils such as crude oils. Jean D. Seguy (to Universal Oil Products Co.). U. S. 2,182,599, Dec. 5. An arrangement of app. is described, and a conversion process which comprises partially vaporizing a hydrocarbon charging oil of relatively wide-boiling range, thereby forming vapors and unvaporized oil, subjecting the latter to cracking conditions of temp. and pressure in a heating coil and sepg. the resultant products into vapors and residual liquid in a sepg. chamber. The residual liquid from the chamber is heated to conversion temp. in a second heating coil and reduced to coke in a coking chamber apart from the sepg. chamber. The vaporous products from the coking chamber are introduced into the sepg. chamber and the vaporous products are sepd. from the heavy pitch-like and tarry materials contained therein as a result of the coking operation, such materials are returned to the second coil in the residual liquid supplied to this coil from the sepg. chamber. The vapors evolved from the charging oil by the partial vaporization are combined with the vapors sepd. in the sepg. chamber; the commingled vapors are fractionated to condense heavier fractions thereof, separate portions of the resultant reflux condensate are supplied to the heating coils, and the fractionated vapors are condensed.

Purifying mineral oils such as refinery charging stocks. Harold C. Eddy (to Petrolite Corp. Ltd.). U. S. 2,182,145, Dec. 5. An arrangement of app. is described, and a process for treating a mineral oil contg. no more than a few percent of water to remove impurities dissolved or dispersed in the oil phase or the water phase, which process includes the steps of: mixing the mineral oil and a relatively fresh water, the mixing being of such a character as to form a mixt. of the relatively fresh water and oil but insufficient to cause a predominant portion of the impurities to become assocd. with the relatively fresh water; subjecting the mixt. to the action of an elec. field to coalesce the water and cause impurities to become assocd. therewith; and sepg. the coalesced water contg. impurities from the oil.

Dewaxing mineral oils. Leon W. Cook (to The Texas Co.). U. S. 2,181,638, Nov. 28. A method of dewaxing a mixt. of wax-bearing oil and dewaxing solvent such as Me Et ketone and benzene contg. a small amt. of water involves incorporating in the mixt. a small proportion of a Cr soap of a higher fatty acid, chilling the mixt. to ppt. wax, and sepg. the pptd. wax; the Cr soap modifies the wax crystals.

Fractionating liquid mixtures such as mineral oils. Merrell R. Fenske and Wilbert B. McCluer (to Pennsylvania Petroleum Research Corp.). U. S. 2,183,094, Dec. 12. Various details of app. and operation.

Stabilizing products such as cracked gasoline against oxidation in the presence of copper or copper compounds. Frederick B. Downing and Charles J. Pedersen (to E. I. du Pont de Nemours & Co.). U. S. 2,181,121, Nov. 28. Catalytic oxidation is inhibited by the addn. (generally of 0.01% or less) of *p*-benzylaminophenol or other compd. of the general formula, HOACH:NRN:CHAOH, where A represents a member of the group consisting of aromatic

rings and unsatd. heterocyclic rings of 5 to 6 atoms in which the hetero atom is N, the OH radical being attached directly to a ring C atom ortho to the —CH=N— group, and R represents an aliphatic radical having the two N atoms attached directly to different C atoms of the same open chain of R. Numerous examples are given. U. S. 2,181,122 relates to the like use of di-(2-hydroxylbenzal)-1,2-diaminobenzene or other oxidation inhibitors of the general formula HOACH:NRN:CHAOH, where A represents a member of the group consisting of aromatic rings and unsatd. heterocyclic rings of 5 to 6 atoms in which the hetero atom is N, the OH radical being attached directly to a ring C atom ortho to the —CH N— group, and R represents a group of the class consisting of aromatic groups, cycloaliphatic groups contg. 6 C atoms in the ring, and heterocyclic groups contg. heterocyclic rings of 6 atoms, the hetero atom being N, and in which the two N atoms are attached directly to adjacent ring C atoms or to the most closely positioned ring C atoms of different rings other than C atoms forming part of the linkage between the two rings of the R group.

Recovering casinghead gasoline. Arthur J. L. Hutchinson (to The Fluor Corp., Ltd.). U. S. 2,181,633, Nov. 28. An arrangement of app. is described, and a process of treating natural gas which comprises, flowing a stream of natural gas contg. hydrocarbons of the methane series, such as pentane and lighter and pentane and heavier, through absorption oil under such conditions of temp. and pressure that the greater part of the hydrocarbons lighter than butane are unabsorbed, removing such unabsorbed hydrocarbons from the system, decreasing the pressure and increasing the temp. on the absorption oil completely to remove all absorbed hydrocarbons, condensing and stabilizing the removed hydrocarbons to recover a liquid fraction contg. some isobutane and a relatively large percentage of hydrocarbons heavier than isobutane also a gaseous fraction contg. some isobutane and a relatively large percentage of hydrocarbons lighter than isobutane, passing the gaseous fraction through absorption oil under lower-pressure conditions than the first-mentioned absorption oil to absorb substantially all propane and heavier hydrocarbons while methane and ethane are substantially unabsorbed, then stepping up the pressure on the last absorption oil to come into contact with the original stream of gas and complete the cycle.

Polymerizing butylene to form gasoline hydrocarbons. Vladimir N. Ipatieff and Herman Pines (to Universal Oil Products Co.). U. S. 2,181,942, Dec. 5. A process for producing gasoline-boiling hydrocarbons from butylene comprises forming a mixt. of propylene and butylene in which the molal ratio of propylene to butylene is less than 3 to 1, and subjecting the mixt. at subatm. temp. to the action of H_2SO_4 of over 90% concn.

Hydrocarbon motor fuels. Harry E. Drennan (to Phillips Petroleum Co.). U. S. 2,181,877, Dec. 5. An arrangement of app. is described, and a process for improving the antiknock characteristics of hydrocarbon motor fuels boiling within the gasoline range, which comprises vaporizing the fuels, superheating the vapors to a temp. of about 260 650°, passing the hydrocarbons while at a temp. within the range into contact with a body of brucite, at a pressure of atm. or higher and at a flow rate sufficient that substantially only a min. of cracking occurs.

Separating oil, gas and water from oil well emulsions or the like. Jay P. Walker (40% to Guy O. Marchant and 6% to C. G. Wells). U. S. 2,181,683 4-5 6-7-8, Nov. 28. Various details of app. and operation.

Device for removing paraffin deposits from gas and oil wells. Geo. F. Penrod. U. S. 2,182,931, Dec. 12. Various structural details.

Lubricating oils. Joseph Cole (to Sinclair Refining Co.). U. S. 2,183,009, Dec. 12. A pour-point depressor for lubricating oils is made by treating chlorinated paraffin wax with stearic acid in the presence of anhyd. $AlCl_3$ (suitably by heating to about 300°) and removing the solid constituents from the liquid product of the reaction (as by filtering).

Hydrocarbon lubricating oils containing metal compounds. Raphael Rosen (to Standard Oil Development Co.). U. S. 2,181,913, Dec. 5. In order to inhibit or reduce sludging, a hydrocarbon oil with a b. p. above that of kerosene is mixed with a metal compd. such as ditolyl-Hg, triphenyl-Bi, triphenylstibine or the like. U. S. 2,181,914 relates to the similar use of metal compds. such as triphenyl Sn iodide, triphenyl butyl Sn, etc., and U. S. 2,181,915 relates to the like use of metal compds. such as various alkyl compds. of Hg, Tl, Sb, Bi or As.

Sulfurized mineral lubricating oil. Martin B. Chittick (to Pure Oil Co.). U. S. 2,181,964, Dec. 5. To form a cutting oil, a mineral oil is used with a minor proportion (suitably about 20%) of sulfopolymers produced from S and unsatd. polymers extd. from gasoline produced by cracking mineral oil.

Device for electric heating of used lubricating oil in a still. Wm. D. Harris (to Refinoil Mfg. Corp.). U. S. 2,181,484, Nov. 28. A device is used which comprises a tubular sleeve closed at one end, and elec. heating unit formed of resistance wire having a porcelain support mounted in the sleeve spaced from the walls thereof, the outer surface of the sleeve being machined smooth and highly polished, a layer of Ni deposited on the outer surface of the sleeve and a layer of Cr deposited on the nickel, a layer of Cr deposited on the interior of the sleeve, and means to mount the opposite end of the sleeve in a still so that its interior is closed to the oil under treatment.

Grease. Vernon L. Ricketts (to Shell Development Co.). U. S. 2,182,137, Dec. 5. See Can. 386,507 (*C. A.* 34, 1844[6]).

Dispersing agent suitable for use with lubricants, detergents, etc. Arthur E. Catanach and Eric Kolthoff (to Gulf Oil Corp.). U. S. 2,181,449, Nov. 28. By the reaction of black sulfuric acid and spent alk. material from the refining of petroleum with use of NaOH or Na_2CO_3, a dispersing and emulsifying material is obtained which is highly sol. in water but sparingly sol. in mineral oils.

Halogen compounds of high molecular weight. Arnold J. Morway and Floyd L. Miller (to Standard Oil Development Co.). U. S. 2,181,144, Nov. 28. Halogenated org. compds. of high mol. wt. contg. more than 1% of halogen such as Cl and suitable for use in *extreme-pressure lubricants* are obtained by halogenation of a substantially satd. linear hydrocarbon polymer of the aliphatic series having a mol. wt. in excess of about 1000 and having a plurality of short alkyl side chains, such as an isobutylene polymer.

Refining liquids such as crank-case oil in engines. John K. Russell, Wm. B. Collins and Walter W. Boggs. U. S. 2,181,608, Nov. 28. App. is described, with use of a refining material such as activated clay in the form of finely divided particles interspersed with lumps of material which serve to restrict settling or packing of the finely divided particles.

Viscometer suitable for testing asphalt, etc. Harold P. Hayden and Herbert E. Schweyer (to Barber Asphalt Corp.). U. S. 2,182,082, Dec. 5. Various structural, mech. and operative details.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Utilization of bagasse for the extraction of cellulose by the Pomilio process in the Philippine Islands. E. Salvatore. *Atti X° congr. intern. chim.* **4**, 173–80(1939)(in Italian).—After a general discussion of the cellulose content of bagasse and of its availability, S. describes briefly a manufg. plant now in construction on Negro Island, P. I., which will produce α-cellulose from bagasse by the Pomilio process. Henri Marc

Composition of some vegetable substances. Yields and chemical and physical characteristics of cellulose produced by the Pomilio process. A. Cittadini. *Atti X° congr. intern. chim.* **4**, 145–55(1939)(in Italian).—A comprehensive study of the yield of cellulose produced by the Pomilio process from the most important plants and trees (short and long vegetable cycles). The results indicate that a white cellulose with good chem. and mech. characteristics can be obtained cheaply by this process. H. M. 1

Micellar structure of cellulose fiber. G. Centola. *Atti X° congr. intern. chim.* **4**, 129–37(1939)(in Italian.)—After investigating the acetylation of natural and mercerized ramie fibers, C. concludes: about 40% of the cellulose is in the amorphous state and acetylates rapidly without altering the dimensions of the cryst. portion of the fiber; under partial acetylation the amorphous portion can be recrystd. and proves to be cellulose triacetate; the mercerizing process increases the content of amorphous cellulose; the amorphous and the cryst. portions of cellulose are so intimately intermixed that not only a sepn. is impossible but not even a deformation of the partially acetylated cellulose can be noticed by the action of liquids which dissolve or swell cellulose acetate. The exptl. results confirm the "fringe micelle" hypothesis of structure for cellulose fiber. 15 references. Henri Marc 2

The use of cellulose from the stalks of sweet sorghum. C. Levi and E. Debenedetti. *Atti X° congr. intern. chim.* **4**, 155–6(1939)(in Italian).—L. and D. report that by treating on an industrial scale sweet sorghum stalks by the monosulfite method following the regular procedure, the raw paste is easily bleached with a quantity of hypochlorite corresponding to 3 to 4% of active Cl_2. The yield in bleached cellulose after the elimination of medular substance and short fiber is around 35%; by mech. improvements the yield on dry material should be increased from the present 10–12% to about 50%. H. M. 3

History of the application of a laboratory method for cellulose determination to industrial production. U. Pomilio. *Atti X° congr. intern. chim.* **4**, 168–72(1939)(in Italian).—After a historical sketch of his industrial method for the extn. of cellulose, P. gives data showing that, of the 4 available methods of chlorination, Cl_2 gas is the most efficient and safest ingredient in liberating cellulose from moist vegetable fibers. Henri Marc 4

Recrystallization of cellulose and of some of its derivatives. G. Centola. *Atti X° congr. intern. chim.* **4**, 117–23 (1939)(in Italian).—After a polarized light and x-ray study of recrystd. cellulose, viscose, cellophane, cellulose acetate and cellulose nitrate, C. concludes that the various factors which can influence the more or less amorphous state of cellulosic materials regenerated from solns. depend on the initial concn. of the soln. and on the conditions under which coagulation takes place (temp., pptn. velocity, nature of solvent and of coagulant and mech. agitation). C. asserts that from exptl. observations it is logical to state that the cellulose mol. does not retain a rectilinear configuration. 8 references. Henri Marc 5

A note on the liquefaction of cellulose. Heou-Fco Tseou and Jen-Shon Sun. *J. Chinese Chem. Soc.* **7**, 33–5 (1939).—Cellulose is impregnated with a strong soln. of NaOH; the mixt. is then dried and fractionally distd. from a Cu retort. The fractions obtained resemble the light oil, kerosene and lubricating oil of petroleum distillate. Wm. H. Adolph 6

Mixed esters of cellulose. I. Nitroacetylcellulose. G. Centola. *Atti X° congr. intern. chim.* **4**, 123–9(1939) (in Italian).—After investigating the prepn. of nitroacetylcellulose by (1) the simultaneous acetylation and nitration of cellulose, (2) the nitration of cellulose acetate and (3) the acetylation of nitrocellulose, C. concludes that its prepn. by a single operation is improbable but that homogeneous products can be obtained by either the nitration of special types of cellulose acetate or by the careful acetylation of nitrocellulose. 11 references. H. M. 7

Acetylation of wood cellulose and preparation of cellulose acetate plastics. A. B. Davankov and A. A. Berlin. *Org. Chem. Ind.* (U. S. S. R.) **6**, 244–9(1939).—A discussion based on literature and some lab. expts. Twenty references. Chas. Blanc 8

Formation of thick cellulose acetate films by the method of continuous pouring. A. A. Moiseev. *Org. Chem. Ind.* (U. S. S. R.) **6**, 319–21(1939).—Films 0.5 ± 0.025 mm. thick and 28 m. long were formed by the method of single and continuous pouring of 28% cellulose acetate in Me_2CO-alc. over a gelatin base at a speed of 0.2 m./min. and air temp. of 50–5°. The solns. were plasticized with 20–30% of triphenyl, tritolyl and tributyl phosphates. The dried films showed mirror-like surface and were free from blisters and other mech. imperfections. In their transparency and colorlessness they are superior to celluloid and cellon and in the mech. properties are equal to cellon but somewhat inferior to celluloid. Numerous tables are given to show the effect of viscosity, plasticizers and other factors on the mech. and optical properties of the resulting films. Chas. Blanc 9

The function of ammonia in cuprammonium cellulose solution. M. I. Arkhipov and A. B. Pakshver. *Org. Chem. Ind.* (U. S. S. R.) **6**, 322–3(1939).—Some addnl. exptl. evidence is presented to show that the viscosity of cuprammonium spinning solns. of cellulose decreases with NH_4OH concn. This effect is more pronounced with stronger cellulose solns. (cf. Pakshver, *et al.*, *C. A.* **31**, 7644[9]; **32**, 1929[1]). Chas. Blanc 10

The trend of progress in the cellulose textile industry. III. Chemical modification of acetate rayon. H. A. Thomas. *Silk and Rayon* **14**, No. 2, 90–2(1940); cf. *C. A.* **34**, 1179[4].—Acetate rayon is "basified" by adding synthetic resins contg. basic groups to the spinning mass, treatment before or after spinning, with polymers of amino derivs. of acrylic acid, or treatment with org. and sulfonic acids or sulfonamides to which a synthetic resin can be added. Stretch spinning can be applied to acetate fibers if they are first swollen with org. liquids or the vapors of these solvents. An important trend is the production of colored yarn by incorporation in the spinning mass of finely dispersed insol. pigments, dyestuffs, or dyestuff coupling components which are rendered insol. after extrusion. This process gives very fast shades. Azoic shades are produced on acetate by applying base and naphthol. Dyeing is done at 60–65° by addn. of HCOOH followed by rinsing in soap and hyposulfite. M. Harris 11

Degree of grinding and chemical decomposition of wood and cellulose fibers. Kurt Hess, Karl Ph. Jung and Karl E. Heumann. *Naturwissenschaften* **27**, 770–1(1939).—The influence of the fiber structure on the course of chem. reactions of vegetable materials was studied. Beechwood disintegrated in a lab. "Vibratom" mill gives a fine powder of 1 to 2 μ size (dry grinding) which is sepd. by a brief treatment with water, alc. and ether. As compared with coarsely pulverized wood such as obtained from a crusher with 270 $\mu \times 1.5$ mm. pieces, the reactivity is greatly increased. The fine powder under normal methylation conditions takes up 36% OMe (98% yield) in one step, the coarse grind only 24–27%. The methylated wood in the first instance is almost completely sol. in BzOH. The fine powder is readily acetylated with Ac_2O-pyridine, giving wood acetate of 40% COMe. Similar improvement in reactivity is found when cellulose fibers are treated. B. J. C. van der Hoeven 12

Production and world consumption of wood pulp. Paul Razous. *Génie civil* **115**, 417–21(1939). A. N. H. 13

National cellulosic resources for paper pulp. C. Levi and M. Marini. *Atti X° congr. intern. chim.* **4**, 157–68 (1939)(in Italian).—A discussion of the chem. and phys. properties of 3 plants available to Italian industry as possible sources of cellulose: (1) *Ampedolesmos tenax*, occurring in Sicily and Calabria, with a cellulose content of about 47.3%, (2) papyrus plant growing near Lake Tana and along the Blue Nile, with a cellulose content of 50.2% and (3) asphadel or silver rod, or king's spear growing profusely in Sardinia, with a 55% cellulose content. Henri Marc 14

Pulp manufacturing from Manchurian "Sirakanba" birch. I. General analysis and cooking by soda process. Hötin Den. *J. Soc. Chem. Ind., Japan* **42**, Suppl. bind-

ing 356–7(1939).—Pulp was made by heating 90-g. samples of air-dried chipped wood from Manchurian "Sirakanba" birches in an autoclave with 280 cc. of cooking soln. (which in different expts. varied from 1.19 to 3.41 *N* NaOH soln.) to 160° during 1.5 hrs., and holding at 160° for 4 hrs. Analyses of the wood (before cooking) and of the pulp (after cooking) are shown for each strength of NaOH soln. used in the cooking operation. A large part of the lignin and pentosan is easily sol. in 1% NaOH soln. The soln. of pentosans increases with increase in NaOH concn., but it is difficult to lower the pentosan content below 3.12%. Cellulose is very easily destroyed by cooking solns. having an NaOH normality above 2.2. The NaOH consumption reaches approx. a max. when 2.8 *N* NaOH soln. is used in the cooking operation.
George Ayers

Limestone in the pulp and paper industry. H. J. Rowley. *Trans. Can. Inst. Mining Met.* 42 (in *Can. Mining Met. Bull.* No. 332), 599–607(1939).—Limestone is used chiefly in the sulfite process; strong acids, formed during digestion, are neutralized in towers. The stone should contain at least 95% $CaCO_3$ and be free of graphite, mica, pyrite and carbonaceous material. Lime has a wider field of use: (1) in the sulfite process, (2) in causticizing in the kraft and soda pulping processes, (3) supply of alky. in rag, rope and straw pulping, (4) in fillers and coatings, (5) in water treatment and (6) in bleach liquor prepn.
Alden H. Emery

Arc welding in pulp and paper mills. H. S. Card. *Paper Ind. Paper World* 21, 753-9(1939).—A brief discussion of the techniques and procedures for welding special alloys and metals used in pulp- and paper-mill equipment.
A. Papineau-Couture

Studies on Japanese papers. I. Physical properties of Japanese papers. Sutezo Oguri and Muneo Takei. *J. Soc. Chem. Ind., Japan* 42, Suppl. binding 300–2(1939).—The thickness, wt., bursting strain, tensile strength and folding no. were detd. (and vol. wt., sp. bursting strain and breaking strength calcd.) for 42 samples of Japanese papers. Papers from Gampi fiber have the best phys. properties except for folding no., those from Kōzo fiber (bast fiber of *Broussonetia kajinoki*) are next best, but superior in folding no., while those contg. admixed sulfite pulp are poorest.
George Ayers

Absorption of SO_2 in water (Jenness, Caulfield) 1. Dialysis through cellulose membranes [permeability of viscose cellulose membranes] (Nowatke) 2. App. with conical devices for sepg. suspended solids from liquids such as waste lye from sulfate cellulose production (U. S. pat. 2,181,456) 1. Waterproofing fibrous materials such as paper (U. S. pat. 2,182,045) 25. Molding material [from sulfite waste liquor] (Can. pat. 386,619) 13.

Chemipulp Sulphite Mill Operation. Watertown, N. Y.: Chemipulp Process, Inc. 191 pp.

Post's Paper Mill Directory. New York: L. D. Post, Inc. 602 pp. $2.00. Reviewed in *Chem. Met. Eng.* 47, 139 (1940).

Cellulose pellets suitable for esterification, etc. Louis S. Baker and Geo. L. Schwartz (to E. I. du Pont de Nemours & Co.). U. S. 2,182,274, Dec. 5. An arrangement of app. is described, and a process of prepg. directly from a cellulose-contg. fibrous pulp slurry, such as one of lint or wood pulp, small pellets of cellulose of uniform size and d.; the process comprises feeding a pulp slurry of papermaking consistency onto a forming screen in the form of uniformly sized platelets or patches, removing free liquid from the pulp slurry by suction through the forming screen, removing the platelets or patches from the forming screen by a rubbing and rolling action exerted by a surface moving in a direction directly opposed to that of the screen whereby the platelets or patches are rolled into pellets, and drying the pellets.

Liberating cellulose from bagasse. John P. Foster and Herman L. Joachim (to Maui Agricultural Co., Ltd.). 1 U. S. 2,181,785, Nov. 28. An arrangement of app. is described, and a process which involves digesting sugarcane bagasse with fiber-liberating chemicals, such as NaOH soln., after a preliminary treatment with a solvent or emulsifying agent to remove cane wax from the fiber bundles of the bagasse.

Cellulose ethers. Henry Dreyfus. U. S. 2,181,264, Nov. 28. A cellulose material such as cotton linters or regenerated cellulose is treated with an etherifying agent 2 such as ethylene oxide or ethylene chlorohydrin in the presence of dimethylaminocyclohexane or the like which serves as an acid neutralizer.

Cellulose esters. Clemmy O. Miller and Arthur E. Siehrs (to North American Rayon Corp.). U. S. 2,181,906, Dec. 5. In prepg. a cellulose ester such as cellulose acetate, an anhyd. alkali metal cellulosate is caused to react with an esterifying agent such as AcCl.

Cellulose ester compositions. Robert P. Russell (to Standard Oil Development Co.). U. S. 2,181,609, Nov. 28. A clear homogeneous compn. suitable for coating various materials comprises a cellulose org. acid 3 ester such as cellulose acetate together with about 0.1% or more of a substantially satd., linear, aliphatic isoölefin polymer such as polyisobutylene having an av. mol. wt. above 800 as detd. by the viscosity method.

Alkali metal cellulosates. Philip C. Scherer, Jr. (to North American Rayon Corp.). U. S. 2,181,919, Dec. 4 5. A cellulose material such as cotton or wood pulp is treated with a soln. of an alkali metal in liquid NH_3, at about the temp. of the b. p. of liquid NH_3 at atm. pressure. U. S. 2,181,920 relates to the production of a product such as cellulose xanthate by treating an anhyd. alkali metal cellulosate with a compd. such as CS_2 under substantially anhyd. conditions (suitably in liquid NH_3).

Moistureproofing sheets of regenerated cellulose. Charles F. Silsby (to Solvay Process Co.). U. S. 2,182,765, Dec. 5. The sheets are treated with a liquid such 5 as acetone which is miscible with the liquids contained in the sheets substantially completely to replace the latter in the surface layers only of the sheets, and the sheets are then impregnated with a soln. of a moistureproofing agent such as a succinic acid-glycerol resin in a solvent such as acetone which is miscible with the liquid first 6 applied, and the solvent is evapd. from the sheets.

Nitrating cellulose. Geo. A. Richter (to Brown Co.). U. S. 2,181,911, Dec. 5. A process of prepg. nitrocellulose from cellulose fiber in the form of paper of a basis wt. ranging from about 30 to about 100 lb. comprises cutting the paper into fragments of a min. span of about $\frac{1}{8}$ to $\frac{1}{4}$ in., treating a mass of such fragments with a mercerizing soln. for at least about 15 min., washing the 7 fragments substantially free from mercerizing soln., drying them, and nitrating the dried, mercerized fragments.

Apparatus for making rayon. Joseph L. Hutchings (to Brosites Machine Co.). U. S. 2,182,540, Dec. 5. Various structural, mech. and operative details.

Stretch-spinning rayon threads from cuprammonium cellulose solutions. Kurt Frowein, Gotthard Bauriedel and Viktor Elsaesser (to American Bemberg Corp.). 8 U. S. 2,182,429, Dec. 5. Various details of app. and operation.

Apparatus for the manufacture of rayon yarns. Ernst Mengeringhausen and Franz Berndt (to North American Rayon Corp.). U. S. 2,182,762, Dec. 5. Various structural, mech. and operative details of an app. with an extrusion spinnerette, etc.

Digestion of fibrous materials. Albert D. Merrill (to Chemipulp Process Inc.). Can. 386,593, Jan. 30, 1940. 9 Relatively cool acid is withdrawn from the acid-storage tank and forced directly into the digester, side relief fluids are sepd. into liquid and gaseous components, and the flowing stream of acid is used to withdraw hot gas from the sepg. zone. An app. is described.

Pulp from highly resinous woods. Kurt Schwabe (to Kübler & Niethammer and Chemische Fabrik Coswig-Anhalt Hans Schraube). U. S. 2,182,520, Dec. 5. In grinding wood pulp from highly resinous woods, there is

added to the pulp, during the grinding operation, Ba(OH)$_2$ which ppts. out the resin as an insol. Ba resin soap, the addn. being limited so that the pH of the pulp water does not exceed 7. Cf. *C. A.* **34**, 625[5].

Apparatus for refining straw pulp, etc. Max Skolnik (to National Fibre Corp.). U. S. 2,182,391, Dec. 5. Various structural, mech. and operative details.

Recovering the solids from pulp mill waste liquors. Erling Fladmark. U. S. 2,182,428, Dec. 5. An arrangement of app. is described, and a method which involves continuously spraying the liquor against the surface of a body of heated liquid heat-transfer medium such as an oil or tar within an evaporator at such a rate of flow that the water of the waste liquor is evapd. upon contact with the surface before the waste liquor and liquid heat-transfer medium can mix while the solid residue of the waste liquor is being continuously absorbed in dry condition by the liquid heat-transfer medium and continuously removed from the evaporator with it. 2 3

Recovering chemicals from cellulose waste liquor. Erkki J. Janhunen. U. S. 2,181,330, Nov. 28. See Swed. 95,611 (*C. A.* **33**, 7114[3]).

Concentrating liquors such as sulfate black liquor in multiple-effect apparatus. William T. Hinckley (to Whiting Corp.). U. S. 2,181,731, Nov. 28. Various details of app. are described and a method of reducing the tendency toward foaming of thin "Black Liquor," in the initial concn. thereof in a multiple-effect evaporator of the long tube vertical type in which liquor flows upwardly through tubes from a low-elevation inlet to a higher-elevation outlet, which consists in introducing such thin "Black Liquor" from a common source simultaneously into a plurality of sub-effects in parallel independent streams, and subjecting the independent streams of liquor in the sub-effects to different temps. and to different degrees of vacuum, and in mixing the treated liquor from both the sub-effects after treatment therein for subsequent treatment in the system. 4 5

Papermaking apparatus. James B. Mehaffey (to Black-Clawson Co.). U. S. 2,182,928, Dec. 12. Various structural, mech. and operative details.

Papermaking machine. William H. Millspaugh (to Sandusky Foundry & Machine Co.). Can. 386,741, Feb. 6, 1940. Structural details. 1

Recovering cellulose ethers from coated paper. Richard D. Freeman (to Dow Chemical Co.). U. S. 2,183,039, Dec. 12. Paper with a coating contg. a cellulose ether such as cellulose ethyl ether is digested with a dil. aq. soln. of an alkali such as Na_2CO_3 while agitating, at a temp. (suitably about 40–100°) at which the cellulose ether is insol. in the dil. alk. soln., until the paper is disintegrated into discrete fibers, and the cellulose ether is sepd. from the slurry of fibers, as by a vibrating screen. 2

Removal of water-insoluble materials from a paper stock. Otto Kress (to Institute of Paper Chemistry). Can. 386,719, Feb. 6, 1940. Shredded paper stock is placed in a container partially filled with water, the water heated by live steam above the m. p. of the waxy materials, the stock agitated, the fibers are sepd. from the melted waxy materials, and the residual waxy materials not removed by hot water removed by addnl. agitation of the stock in an aq. medium contg. a soap-emulsifying agent and an alkali soln. of a water-insol., alkali-sol., acid-precipitable protein. 3

Calcium carbonate for coating paper, etc. Howard Roderick (to Michigan Alkali Co.). U. S. 2,182,096, Dec. 5. A method of making a $CaCO_3$ coating pigment for paper, etc., involves pptg. $CaCO_3$ from reacting solns. of Na_2CO_3, $NaHCO_3$ and $CaCl_2$, in which the relative concn. of Na_2CO_3 to $NaHCO_3$ is in the range of $2^1/_2$–$3^1/_2$ to 1, in the presence of an excess of $CaCl_2$, and agitating and heating such reacting solns. during pptn. in a temp. range of 65–105°. Cf. *C. A.* **33**, 8367[6]. 4

Moistureproofed glassine paper suitable for use as a wrapping material. Fred K. Shankweiler (to Hercules Powder Co.). U. S. 2,181,160, Nov. 28. Glassine paper is coated with a substantially transparent thin film of a compn. contg. chlorinated rubber and a wax such as beeswax or montan wax or paraffin. 5

Paper suitable for cartons for packing fragile glassware, etc. Sidney D. Wells (50% to Gerald D. Muggleton). U. S. 2,181,556, Nov. 28. A paper of good density and strength is formed from 85–50% waste paper stock and 15–50% of nonfibrous pithy material from which the fibrous portions have been substantially removed.

24—EXPLOSIVES AND EXPLOSIONS

C. G. STORM

Production of explosives in the United States during the calendar year 1938. W. W. Adams, V. E. Wrenn and L. S. Horton. *U. S. Bur. Mines, Tech. Paper* **606**, 28 pp.(1939); cf. *C. A.* **33**, 3855[8]. Alden H. Emery 7

Ammonium nitrate as a military explosive. M. Ovchinnikov. *Tekh. i Vooruzhenie* **1938**, No. 12, 77–8; *Khim. Referat. Zhur.* 2, No. 4, 135(1939).—The phys. properties of NH_4NO_3 are described. Notwithstanding its hygroscopisity and tendency to pack, it is recommended for use as an explosive. W. R. Henn

Ignition of firedamp by explosives. Étienne Audibert. *Rev. ind. minérale* No. **448**, 1–7(1940).—The explosives used consisted of varying proportions of gelatinized nitroglycerin (1/40), NH_4NO_3, wood flour and (KCl + NaCl), in such amts. that on explosion all C and H are completely oxidized. It was made up into cartridges of 30 mm. diam. and varying length. They were fired in a steel mortar 35 mm. diam. and of varying length, either undamped or damped by means of a steel plate at the top of the mortar, offering varying resistance to its removal by the explosion, which was started from either the bottom or top of the cartridge; the expts. were conducted in an atm. contg. CH_4. Results showed that (1) damping is only effective in restraining ignition of the firedamp when the velocity of decompn. of the explosive is sufficiently great e. g., when with the above explosives the amt. of nitroglycerin is not above 20%; accordingly tamping must be more complete with a slow burning powder, such as those with NH_4NO_3 as basis; (2) as regards increased risk on increasing the charge, provided the ratio (length of charge)/(length of mortar) is const. the risk decreases with increased length of charge; (3) provided tamping is sufficient to ensure complete decompn. before emergence of the gases produced, it makes no difference from which end of the cartridge it is fired. From the above safe limits for the compn. of powders are: gelatinized nitroglycerin (1/40) 14, 20 and 25%, NH_4NO_3 42.02, 34.72 and 28.77%, wood flour 5.98, 5.28 and 4.23%, (KCl + NaCl) 38, 40 and 42%, giving per 100 g., 64.30, 67.50 and 68.10 cal., resp. C. A. Silberrad 8

Determination of pressure in the air compression wave resulting from explosions. Wilhelm Schneider. *Z. ges. Schiess- u. Sprengstoffw.* **34**, 230–4, 263–6, 284–6, 304–6, 329–31(1939).—The differences between the air compression wave from explosions and sound waves are discussed theoretically and mathematically. An app. with vibrating membrane was developed, which showed the max. pressure from a charge of 1 kg. of TNT to be 2.7 g./sq. cm. at a distance of 160 m. and 1.7 g./sq. cm. at 240 m. C. G. Storm 9

The causes of a [tar-] distillation explosion. Paul Riehm. *Teer u. Bitumen* **37**, 305–6, 348–9(1939).—Explanations are offered for an explosion with fatalities which occurred with the draining of a distn. vessel when a tar fire was being extinguished. F. W. Jung

Explosion limits of industrially important gases and vapors of solvents. Freitag. *Oberflächentech.* **17**, 7 (1940).—The lower and upper explosion limits in percent-

age by vol. in air are CO 12.5, 74; H 4.1, 74; ethylene 4.0, 14.2; CH_4 5.3, 14.0; C_2H_2 2.5, 80.0; NH_3 16.0, 27.0; illuminating gas 7.0, 21.0; benzene 1.4, 8.0; EtOH 3.0, 19.0; ether 1.7, —; benzine 1.4, 6.0; acetone 3.0, 9.0; CS_2 2.0, 32.0; MeOH 6.0, —; MeCl 8.1, 17.2. M. Hartenheim

Flue-gas explosions. F. J. Matthews. *Colliery Eng.* **16**, 395–6(1939).—Every boiler fire is capable of giving off a mixt. of hydrocarbons and other gases which can explode with a small amt. of air under the right conditions. Gas pockets in flues should be avoided and draughts maintained in good conditions. Air should flow through the furnace and flues for 10 min. before breaking up a banked fire. Firing of waste fuels, such as sawdust, should be avoided. Ann Nicholson Hird

Chemical fire fighting in U. S. S. R. F. Mikhailov. *Pozharnaya Tekh.* **1938**, No. 5, 14–16; *Khim. Referat. Zhur.* **2**, No. 4, 143–4(1939).—Aq. solns. most effective for fire extinguishing were $CaCl_2$, NaOH, KNO_3, H_3PO_4, and water glass. Other suitable fire-extinguishing substances were CCl_4 (methods for removal of the phosgene formed during the decompn. of CCl_4 from the action of fire must be devised), CO_2 snow (for hard objects and combustible liquids) and dry powders in combination with CO_2 and steam. W. R. Henn

A method for fighting underground fires. D. V. Ermuzevich. *Ugol* **1938**, No. 11, 36–8; *Khim. Referat. Zhur.* **2**, No. 4, 144(1939).—Causes for underground fires in coal mines and methods for fighting them are described. W. R. Henn

Research work in the [fire] department. Anthony J. Mullaney. *Fire Eng.* **93**, 52–4(1940).—A survey of new developments in the methods of fire control and prevention. Leopold Scheflan

An electron-metal fire. Braukmann. *Oberflachentech.* **17**, 4–6(1940).—In an investigation of the causes of a fire in an electron (Mg-Al alloy) factory it was established that the use of acid oils in grinding is a source of grave danger, as they develop H and can be ignited at temps. as low as 110°, which temp. is easily reached in the grinding processes. The ignition point of the oil is lowered considerably by admixts. of Mg dust, as is the case in grinding. To avoid danger of fire in such plants (1) a neutral oil must be employed, (2) all machines and accessories must be of incombustible material, (3) grinding machines should be at least 3 m. apart, (4) used emery paper and other inflammable material must not be permitted to accumulate and machines must be cleaned 3–4 times during a shift. M. Hartenheim

The laws of combustion of (colloidal) powders. J. Dupuis. *Mém. artillerie franç.* **17**, 799–830(1938).—The law of combustion for powders, generally adopted after the works of Charbonnier, is $dz/dt = A\phi(z)f(P)$, where z is the fraction of the powder burned at instant t, A is const. for given conditions, $\phi(z)$ and $f(P)$ are functions of z and P, resp. (both independent of Δ, d. of loading). Closed-bomb exptl. results give the relation of dz/dt and P, thus detg. $f(P)$. ($\phi(z)$ is calcd. in the interval $z = 0.1$ to $z = 0.8$, on the assumption that burning is in layers.) Except at low-pressure levels, $f(P)$ appears to take forms such as $P^{0.85}$, $P + 200$ kg., $P^{2/3}$, with equal accuracy. This indicates that expts. of others were conducted at too low a Δ, permitting natural variations in the powder to affect the results. $f(P)$ detd. by Muraour takes the form $K(P + A)$, which is very close to that proposed by D. It is concluded that the theory of combustion in parallel layers is valid, contradictory phenomena being attributed to heterogeneity of the powder; and that the linear velocity of combustion is not proportional to the pressure. H. Muraour. *Ibid.* 831–3.—Various references are given on work of M., with brief comments on each phase. Burning of powder grains in parallel layers is reaffirmed as the proper basis for the laws of combustion. The law $V = a + bP$, deduced previously from exptl. results, is in perfect agreement with the conclusion of Dupuis (above). V represents linear rate of burning, P is the pressure at the corresponding instant, a and b are consts. for particular conditions. At higher values of P, a becomes negligible. B. E. Anderson

Silico-calcium [as thermite in explosives] (Bergeret) 4.

Weingart, George W.: Pyrotechny. Revised ed. New York: Chemical Publishing Co. $5.00. Reviewed in *Pacific Chem. Met. Inds.* **4**, No. 2, 8(1940).

Extinguishing burning light metals and preventing their ignition. Fritz Kotz and Armin Bergmann (to Junkers Flugzeug- und Motorenwerke A.-G.). U. S. 2,182,440, Dec. 5. The metal is wetted with a dil. aq. soln. of a silicate such as Na silicate, contg. particles of a saponifiable oil such as lard oil dispersed in the soln. Cf. *C. A.* **33**, 2340[6].

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Some recent advances in fluorescence analysis as an aid to the textile colorist. Julius Grant. *Textile Colorist* **62**, 9–11(1940); cf. *C. A.* **30**, 6569[7].—A review of advances during the past four years. Certain dyestuffs, which when in soln. do not normally fluoresce in filtered ultraviolet light, can fluoresce in a characteristic manner when dyed onto certain textile fibers. The same dye may fluoresce differently on different fibers. Improvements in ultraviolet lamps are cited. The application of the "ultrachromatographic adsorption" method to mixts. of dyes is described. Ruby K. Worner

Preparation of azo dyes from dimethoxyanthranilic acids. A. S. Chernyshev and B. M. Bogoslovskiĭ. *Org. Chem. Ind.* (U. S. S. R.) **7**, 254–6(1939).—2-Amino-3,4- and 6-amino-2,3-dimethoxybenzoic acid, obtained from hemipinimide by Rodionov and Fedorova (*C. A.* **33**, 5827[7]), when diazotized and coupled with PhOH, R acid, H acid and naphthionic acid, gave bright dyes and orange to violet dyeings fairly stable to light and soap. C. B.

Some new azo derivatives of sulfanilamide. Antonio Mossini. *Ann. chim. farm.* (Suppl. to *Farm. ital.*) Dec., **1939**, 47–53.—At 0° in aq. soln. diazotized sulfanilamide (I) reacts with Na barbiturate to form *p*-sulfonamidobenzeneazo-5-barbituric acid (II), a red dye decompg. without melting at 204°. I with Et acetoacetate and NaOH in aq. alc. forms *p*-sulfonamidobenzeneazo-3-acetoacetic acid, pptd. by acids as a yellow powder, decompg. without melting at 182°. Aminobenzene-4-sulfonamidobenzene-4′-sulfondimethylamide (III), $Me_2NSO_2C_6H_4NHSO_2C_6H_4NH_2$, after diazotization of the free NH_2 group, reacts with barbituric acid to form 4″-sulfondimethylamidobenzene - 4′ - sulfonamidobenzeneazo-5-barbituric acid (IV), an orange dye melting with decompn. at 258°. Diazotized III reacts with Et acetoacetate to form 4″-sulfondimethylamidobenzene-4′-sulfonamidobenzeneazo - 3 - acetoacetic acid, an orange dye, m. 200°. All 4 of the above dyes are insol. in cold water, C_6H_6 and petr. ether, sol. in EtOH, Me_2CO and aq. alkalies. Reduction of II and IV with Sn and HCl gives 5-aminobarbituric acid and other products. L. E. G.

Dyes and tans in the species of statice. C. D. Mell. *Textile Colorist* **62**, 59–60(1940). Ruby K. Worner

Vat dyes of the benzanthrone series. XXI. Synthesis of benzanthroneacridone and constitution of indanthrene-olive green B. Tosio Maki and Arumi Kikuti. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 310–17(1939)(in German); cf. *C. A.* **30**, 2009[2].—Br (11.2 g.) in 57.5 g. AcOH was added dropwise to a stirred soln. of 11.5 g. benzanthrone and 0.35 g. I in 173 g. AcOH maintained at 80°; after heating 5 hrs. at 100°, the crystals were filtered

off, washed with AcOH and then with H_2O; yield, 12.9 g. of 3-bromo-7-benz[*de*]anthren-7-one (I), yellow needles (after recrystn. from AcOH), m. 173.5° (corr.), and colors H_2SO_4 carmine red (no fluorescence). I (3.09 g.), 2.50 g. of 1-aminoanthraquinone, 0.2 g. anhyd. NaOAc and 0.3 g. of Cu_2Cl_2 were finely ground and refluxed 15 hrs. in 50 g. $PhNO_2$; subsequently at approx. 70° 50 cc. alc. was added and the yield of ppt. after washing with very dil. HCl was 86.48%. After recrystn. from *o*-$C_6H_4Cl_2$, 2 *N*-(7-oxo-7-benz[*de*]anthren-3-yl)-1-aminoanthraquinone (II) was obtained as a dark brown cryst. powder giving a violet-brown mark, a dark-brown nonfluorescent color in H_2SO_4 (violet-brown ppt. on diln.) and having slight soly. (0.45 g./100 cc.) in PhCl, but sol. in *o*-$C_6H_4Cl_2$ and $PhNO_2$ with a brown-red color (nonfluorescent). With alk. hyposulfite at 60–70°, II is inferior as a dyestuff. II (1 g.) was added at 110° to a mixt. of 20 g. of 83% KOH, 16 g. PhOH and 4 g. of 98% alc. which had previously been melted together at 135°, then the material was heated 2 hrs. at 135°. After digestion with 1 l. of water, the insol. product was filtered off and treated with dil. HCl; the crude product (0.98 g.) was refluxed with 300 times its quantity of PhCl for 2 hrs., then the residue, after washing and drying (0.85 g.), formed a dark-green powder difficultly sol. in PhCl and somewhat sol. in *o*-$C_6H_4Cl_2$ and $PhNO_2$ and gave a green soln. (no fluorescence) on heating. The powder (0.5 g.) was dissolved in 50 cc. concd. H_2SO_4 and set aside for 2 hrs., then poured into water, yielding 0.5 g. of "benzanthroneacridone" ($C_{41}H_{15}O_3N$) (III) which when recrystd. from $PhNO_2$ forms blue-green scales. When used in a hyposulfite vat at 55–60°, III dyes cotton olive-green; under the same conditions III if not purified by H_2SO_4 treatment gives a more gray shade. Com. Indanthrene-olive Green B contains about 50% of actual dyestuff and is impure III as shown by tests. George Ayers

An interesting chapter in vat-dye progress. A. J. Hall. *Am. Dyestuff Reptr.* 29, 58–60, 68–71(1940).—The Indigosol and Soledon dyes are simply dissolved in water, applied to yarn or fabric by padding or by much the same easy method of dyeing cotton with direct dyes or wool with acid dyes and the textile material is then treated with an acid oxidizing liquor. Methods of producing these dyes are outlined, also their chem. constitution. Patented expedients to prevent overoxidation in the development process are discussed. Hydroquinone substances should be of much assistance to dyers and printers of vegetable and animal fiber materials with Indigosols and Soledons. Other buffers include thiocyanates of Cu and NH_4, thiodiglycol, thiourea, *o*- or *p*-dihydroxy- and *o*- or *p*-hydroxyamino-aromatic compds. Overoxidation can be prevented where the dyed material is developed in 7 an oxidizing bath and not by steaming treatment. Suitable reducing agents are $SnCl_2$ and $TiCl_2$. Although present with the oxidant (HNO_3) in the developing bath, they do not immediately attack and reduce this before it has the opportunity to oxidize the dye. W. H. Boynton

Bright fast pinks. Raffaele Sansone. *Textile Colorist* 61, 817–19(1939).—Formulas and dyeing procedures are given for printing bright, fast, pink colors on cotton and acetate rayon. Ruby K. Worner

The technique of breaking down dyes. Joseph Rière. *Teintex* 4, 660–8(1939).—R. reviews the use of the following substances used for breaking down dyes: oxidizing agents HNO_3, $Na_2Cr_2O_7$, Cl_2-H_2O, $KMnO_4$; reducing agents hyposulfites and sulfoxylates; alk. agents soaps, NH_3, NH_4OAc, Na_2CO_3, NaOH; acid agents HCOOH, HOAc and H_2SO_4. Sample baths are given for use with cotton fabrics contg. basic dyes, S dyes, vat dyes and insol. azo dyes. Bath formulas for viscose rayon, acetate rayon and wool fabrics are also included. S. Z.

Superior fast umbrella fabrics. Raffaele Sansone. *Textile Colorist* 62, 20–4(1940).—Dyes and dyeing procedures are given for producing fast colors on different types of umbrella fabrics at reasonable costs. R. K. W.

Oxidizing agents in dyeing with aniline black. R. Viart. *Teintex* 4, 659–60(1939).—Methods are outlined 1 for the analysis of chlorates and dichromates that are used as oxidizing agents with aniline black. S. Z.

Dyeing wool and cotton materials for the services. T. E. Thompson. *Dyer* 82, 325, 330(1939).—Suggestions are given for dyeing textiles to meet the requirements of the military services. The use of vat, chrome, sulfur and direct dyes is considered. Ruby K. Worner

Continuous dyeing of wool and half-wool: Method based on the theory of turgescence. E. Justin-Mueller. *Teintex* 4, 656–9(1939).—Important factors considered 2 are: (1) the fabric must be clean and dry and the dye bath kept at 80°, 90° or 95° depending on the dye used, (2) the concn. of the dye bath must be such as to give the max. desired intensity in 20 sec., (3) the dye must be well dissolved, (4) in a mixt. of dyes all must have the same soly., (5) on entering the dye bath, the dry cloth must be completely wetted. A schematic drawing of the con- 3 tinuous process is included. Saverio Zuffanti

The black dyeing of mixed woven fabrics containing acetate rayon. R. Langer. *Farber u. Chemischreiniger* 1939, 122–3; *Chem. Zentr.* 1939, II, 4357.—Directions are given for the dyeing of various com. mixtures and suitable dyes are named. Leopold Scheflan

The dyeing of clothing and the dye and textile-assistant industries. H. Collé. *Färber u. Chemischreiniger* 1939, 104–7, 116–18; *Chem. Zentr.* 1939, II, 3752.—A general 4 review of the various types of dyes with fastness requirements. Leopold Scheflan

The dyeing and finishing of heavy clothing fabrics from staple rayon and German shoddy. L. Jackel. *Klepzig's Textil-Z.* 42, 771–2, 774, 789–91(1939).—An address. Leopold Scheflan

The examination of dyeings in textiles of vegetable and animal origin and in mixed woven fabrics. Carl Blau, Jr. *Farber u. Chemischreiniger* 1939, 43–6; *Chem. Zentr.* 1939, II, 1383.—A summary of known methods of testing 5 for all types of dyes. Leopold Scheflan

The dyeing of staple-rayon woven fabric mixtures according to the semiwool metachrome process. Pusch. *Farber u. Chemischreiniger* 1939, 32–3; *Chem. Zentr.* 1939, II, 1171.—Descriptive. Leopold Scheflan

The dyeing of cotton. Frische. *Färber u. Chemischreiniger* 1939, 20–2; *Chem. Zentr.* 1939, I, 3962.—A 6 discussion of the structure of cotton and phenomena occurring during dyeing operations. Leopold Scheflan

Dyeing casein fibers. C. H. S. Tupholme. *Textile Colorist* 61, 803–6, 852(1939).—The manuf., properties, and dyeing of casein fiber are described. R. K. W.

The dyeing of jute. D. Carter. *J. Textile Inst.* 30, P328–39(1939); cf. *C. A.* 34, 6302.—A brief survey is given of the literature on the subject, followed by descriptions of methods of dyeing jute using basic, acid, direct 7 cotton, sulfur, vat, and azoic dyestuffs. R. K. W.

Dyeing pale shades on jute with neutral acid colors. C. Wouble. *Textile Colorist* 62, 58(1940).—Practical. Ruby K. Worner

Technique of dyeing and printing on combed ribbon. Louis Bonnet. *Teintex* 4, 566–71(1939).—Considerable detail is given regarding the washing of wools, their degreasing, and bleaching. Dyeing and printing details 8 with several bath formulas are included. S. Z.

New ideas in rayon printing and characteristics of that technique. P. Baffroy. *Teintex* 4, 571–6(1939).—Details of a cleaning process for rayon pieces are given. To minimize swelling of the fibers the pieces are treated with 8–12°Bé $Al(OAc)_3$ and dried at a moderate temp. The pH must be carefully watched to prevent $Al(OH)_3$ from forming and also to prevent too much free acid. In rayon printing substantive dyes, basic dyes, mordant 9 dyes, vat dyes, the indigosols, the Rapidogens and aniline black are used. On pure rayon, vat dyes are used chiefly because of simplicity of application. Thickening agents mixed with the vat dyes are starch, tragacanth, and gum arabic. Much detail regarding the use of the above dyes is given. Sample dye-bath formulas are included. Saverio Zuffanti

Screen printing on nontextile surfaces. G. S. Ranshaw. *Dyer* 82, 255–6(1939).—Modifications and precautions

are given for applying screen printing procedures to such materials as oilcloth, leathercloth, rubberized fabrics and plastic materials, including Pliofilm and cellophane. Ruby K. Worner

Embellishing printed goods through spray printing. Raffaele Sansone. *Textile Colorist* **61**, 768–72(1939).—Applications and advantages of spray printing are cited. Formulas are given. Ruby K. Worner

Mordanting of silk with chromium salts. IX. K. Hisiyama. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 352–5(1939); cf. *C. A.* **31**, 6887[9].—From an inspection of absorption curves for $Cr_2(SO_4)_3$ and Cr_2Cl_6 solns. for wave lengths between approx. 3700 and 6500 A., $Cr_2(SO_4)_3$, which has greater mordanting efficiency than Cr_2Cl_6, is more bathochromic and hyperchromic. Both hyperchromic and bathochromic effects are produced either (1) by raising the temp. of the solns. or (2) by increasing the basicity of the salts, thus indicating that with increase of temp. hydrolysis increases, producing basic Cr salt and free acid. NaCl has little or no effect on absorption by Cr_2Cl_6 soln., but Na_2SO_4, especially at 96°, added to Cr_2Cl_6 soln. shows the hyperchromic and bathochromic effects of $Cr_2(SO_4)_3$. If it is assumed that light absorption by the Cr salts is due not to the salts themselves but to the semicolloidal basic Cr salts (Cr hydroxide adsorbing acid radical), then there exists a close relationship between mordanting efficiency and absorption curve of the mordanting liquor. George Ayers

Intermittent coloration of cotton, rayon, wool, and silk threads used to produce spotted and striped effects on weaving. P. Merey. *Teintex* **4**, 588–91(1939); cf. *C. A.* **33**, 3592[6].—A discussion of the equipment used for this process. Drawings of the equipment are included. Saverio Zuffanti

Tone-in-tone style. H. P. Baumann. *Textile Colorist* **62**, 49–50, 60(1940).—Formulas are given for tinting white discharge prints after processing. Since the 2nd dyeing covers the original dyeing as well as the white discharge, the style is called "tone-in-tone." R. K. W.

The use of fuller's teasel among the dyers and cloth manufacturers. C. D. Mell. *Textile Colorist* **61**, 777 (1939).—Fuller's teasel (*Dipsicus fullerum*) yields a yellow dye and tannin. Its chief importance in the textile industry, however, is the use of its globular flowering head for raising the nap on cloth. Ruby K. Worner

The early days of the (British) Textile Institute. Geo. Moores. *J. Textile Inst.* **30**, P400–3(1939). R. K. W.

Textile progress. E. W. K. Schwarz. *Textile Colorist* **62**, 25–9(1940).—An address. Among the developments reviewed are the use of phthalocyanine pigments in textile printing and dyeing (Aridye process), the role of resins in textile processing and for water softening, rubberizing treatment for wool fibers, wool carpet with rubber latex base, use of quarternary-ammonium compounds in finishing, Velan waterproofing process, and the new textile fibers, notably casein, glass, nylon, and vinyon. Ruby K. Worner

Toward the simplification of textile-chemical processes. J. Wakelin. *Textile Colorist* **61**, 731–5, 780(1939).—Short cuts in bleaching cotton, simplified procedures in dyeing with azoic dyes and aniline black, and merging of operations for producing crease resistance and water-repellency are cited as examples of simplification in textile processing. Ruby K. Worner

Important chemical developments in the textile industry. E. W. K. Schwarz. *Textile Bull.* **57**, No. 11, 12, 16–17; No. 12, 19, 47, 50–1, 54–5(1940).—Sec *C. A.* **34**, 1490[3]. Leopold Scheflan

Vinyon—a new textile fiber. F. Bonnet. *Textile Bull.* **57**, No. 11, 18–19, 31(1940); *Can. Textile J.* **57**, No. 4, 38, 40–1(1940); cf. *C. A.* **34**, 1490[6].—A discussion of vinyl chloride and acetate, the blending of resins prepd. from them, industrial uses, the manuf. of vinyon, tenacity and elongation control, high chem. resistance of vinyon yarns and fabrics to acids and alkalies, methods of dyeing and com. applications. L. S.

Protein artificial fiber. I. Spinning of casein alkali solution. H. Z. Utaka, K. Nasu and S. Oriu. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 397–8(1939).—The dispersion of casein alkali solns. was markedly improved by addn. of small quantities of Cu, Ni, Co, Fe or Zn hydroxides, resulting ultimately, after processing, in beautiful wool-like casein fibers. A change in the degree of dispersion of the casein soln. does not appreciably affect the tensile strength or elongation of casein fiber, but a change in spinning velocity or addn. of a large quantity of metallic hydroxide gels does exert a marked effect. Data on the ripening time of casein alkali soln. are given. Mg salts, formalin, acids, etc., were used as coagulating media; for permanent coagulation in a properly concd. soln., 48–72 hrs. or more is required. Casein fiber thus obtained had a max. tensile strength of 1.3 g. per denier and the elongation was 14.0%. **II. Manufacture of soybean-protein fiber.** H. Z. Utaka and K. Nasu. *Ibid.* 398.—Soybean protein was softened in water and dispersed in a soln. of NaOH, KOH or NH_4OH. A mixt. of equal parts of this alkali soln. and casein soln. was forced through spinnerets (of the rayon type) into a coagulation bath contg. an inorg. or an org. acid and Mg salts. The fiber, which was wool-like and faintly yellow, had an av. tensile strength of 0.71 g. per denier and elongation of 5.2%. George Ayers

Effect of climatic exposure on textile fibers and fabrics. A. C. Thaysen, H. J. Bunker, K. R. Butlin and L. H. Williams. *Ann. Applied Biol.* **26**, 750–81(1939).—Fabrics were exposed to bacterial attack under a variety of climatic conditions. Exposure of cellulose fibers in sun and shade caused a lowering of viscosity; but from soil exposure, with more extensive microbiol. destruction, there was no effect on viscosity. Viscosity measurements on Indian, Egyptian and American cotton are shown in graphs. All sun- and shade-exposed fabrics, including silk and wool, increased in acidity during the first 3 months of exposure but showed little increase on further exposure. In microbiologically active soil, cellulose acetate rayon was completely resistant while cellulose, wool, silk and cellulose rayon fabrics disintegrated. C. H. R.

Reserve effect on artificial fiber cloths. Louis Denis. *Teintex* **4**, 669–70(1939).—D. explains the treatment and dyeing of mixed acetate and viscose rayon cloths where it is desired to dye one and not the other and vice versa. Saverio Zuffanti

Mongolian sheep wool. VI. Behavior of Mongolian sheep wool toward dyes. Mitio Saito and Tadasige Tinzei. *Rept. Inst. Sci. Research Manchoukuo* **3**, 276–82 (1939)(Abstracts in English); cf. *C. A.* **33**, 7577[7].—A comparison of the dye-absorbing ability of Mongolian sheep wool with that of merino wool indicated that the former generally absorbed more dye, especially basic or direct dyes. This is in accord with previously reported findings that the former is also more susceptible to chem. reagents, and is interpreted to mean that Mongolian wool is either composed of more loosely combined materials or more labile compds. **VII. Difference of the length, the fineness, the composition and the general quality of Mongolian sheep wools obtained from different parts of the sheep body.** *Ibid.* 283–301.—The av. semi-annual yield of wool from Mongolian sheep was 944 g. per head. The fiber varied in grease and suint contents from 2.6 to 10% and 4.5 to 12%, resp., depending on the part of the sheep body from which they were taken. The relative amts. of coarse and fine wool in the fleece also varied with location on the sheep body, the back, side and shoulder parts contg. 15 to 38% of coarse fibers, compared with 60% in the top and arm piece parts. The longest fibers were found in the fleece, back and neck parts. The data indicate that the best quality of wool is obtained from the back, fleece, side and shoulder parts of the sheep body. Milton Harris

Problems of wool research for science and industry. E. Elöd. *Klepzig's Textil-Z.* **43**, 105–6(1940).—An address. Leopold Scheflan

Felting-fulling of wool cloth. Louis Bonnet. *Teintex* **4**, 620–31(1939).—A detailed review of felting-fulling is developed historically. References. Saverio Zuffanti

Manufacture and properties of lanital, artificial wool.

derived from the casein of milk. Lo Duca. *Génie civil* 115, 317–20(1939).—Recent improvements in Ferretti's method as carried out in Italy are discussed. The toughness and elasticity of lanital have been greatly increased. Chem. and microscopic tests for distinguishing between natural wool and lanital are given. Production in Italy has fallen off about 50% since 1938 owing to lack of milk. Ann Nicholson Hird 1

Note on lanital—its determination in wool mixtures. Eliseo T. Huergo. *Industria y quim.* 2, 177–81(1939).—The method proposed for the detn. of the lanital content of wool mixts. is based on the fact that wool contains only traces of P, while lanital, being a casein, contains considerable fixed amts. of P. An analysis of the ashes of a burned sample, yielding their content of P_2O_5, therefore throws light on the compn. of the sample. The advantages of this method over those used heretofore are pointed out in conclusion. 7 references. A. H. Krappe 2

Effect of water vapor on wool fibers. J. M. Gaudit. *Teintex* 4, 618–19(1939).—The important spinning mills that prep. skein wool steam the cops in an autoclave under reduced pressure for a few min. This operation gives the skeins a very regular and flexible quality but it does not eliminate the sponging prior to dyeing. S. Z. 3

The action of alkalies on wool. E. Schmidt. *Teintex* 4, 563–6(1939).—Treating wool with alk. solns. produces 3 effects: (*a*) the wool absorbs a certain amt. of the alkali, (*b*) more or less swelling occurs, (*c*) the keratin mol. is hydrolyzed. Hydrolysis occurs more readily in alk. than in acid soln. Swelling of wool increases with the pH. The action of the following substances is discussed: caustic alkali, alk. earths, NH_3, Schweitzer's soln., org. bases, alk. carbonates, borax, Na_3PO_4, silicates and soaps. Saverio Zuffanti 4

Effects of concentrated aqueous and certain nonaqueous solutions of alkali upon wool. Martin R. Freney and M. Lipson. *Nature* 145, 25–6(1940).—The S and N contents of merino wool are scarcely altered by immersion in 52% NaOH up to 30 min. The surface structure of the fiber is unaltered by similar treatment up to 5–10 min. Wool treated with concd. NaOH absorbs acid dyes evenly and a woven fabric treated with 52% NaOH soln. shows a decrease in shrinkage on washing. E. D. Walter 5

Some detergent problems of the woolen and worsted industries. H. Phillips. *Wetting and Detergency Symposium*, Feb. 19–20, 1937, *Brit. Sect. Intern. Soc. Leather Trades' Chem.* 175–83. **The penetration of fabrics by detergent solutions.** J. Powney. *Ibid.* 185–96.—Reviews. M. M. Piskur 6

The influence of science on the cotton industry. F. C. Toy. *J. Textile Inst.* 30, P387–99(1939).—An address. Ruby K. Worner 7

The reactions of cellulose fibers and their materials during bleaching. P. Merey. *Teintex* 4, 531–7(1939).—Na_2CO_3 is better than NaOH for removing grease from cotton. Petroleum hydrocarbons, turpentine and tetralin are added more easily to liquefy the waxes. Waxes, which consist of unsaponifiable substances, alcs. of high mol. wt., and unsaponifiable esters and acids such as cerotic, and carnaubic acids which form insol. soaps are difficult to remove. The glycerides of palmitic, stearic and oleic acids become sapond. easily. From the alk. ext. can be formed alk. salts and amino acids such as dihydroxy- or dimethoxyphenyl-α-aminopropionic acid, which sep. from the stable pectins along with galacturic acid and similar compds. Hydrolysis of the ext. and decompn. of the pectins give acids and sugars (pentoses, hexoses). M. discusses the boiling and bleaching of linen and gives the conditions of operation. Chlorination makes the lignopectins sol. in alk. solns. The hypochlorites used for bleaching act as chlorinating agents as well as oxidants. Chloropropionic acid was identified in the alk. ext. Saverio Zuffanti 8

The science of jute. S. G. Barker. *J. Textile Inst.* 30, P273–304(1939).—The formation of jute fiber in the plant; the chem. nature of jute; the measurement of color and luster of jute fibers; strength; the influence of strength of atm. conditions, constituents (wax, pectin, and lignin), and various chem. treatments; and the moisture relations are discussed. A note on the nature of crude jute fiber is included. Cf. following abstrs. R. K. W. 9

The production of jute. R. S. Finlow. *J. Textile Inst.* 30, P352–73(1939).—Deals chiefly with its cultivation in India. Ruby K. Worner

Chemistry in the processing of jute. Herbert L. Parsons. *J. Textile Inst.* 30, P311–7(1939).—The phys. and chem. properties of jute are described and compared with those of cotton and flax. The prepn. of jute for spinning, including retting and batching, warp dressing, bleaching, assessing chem. attack, mercerizing and woolenizing, dyeing, rotproofing, waterproofing and fireproofing are described. Ruby K. Worner

The swelling of jute fibers. W. G. Macmillan. *J. Textile Inst.* 30, P305–10(1939); cf. *C. A.* 33, 7575[8].—A discussion of the swelling properties of jute, including descriptions of methods for measuring swelling. Direct methods include measurement of the fiber diam. using a microscope and micrometer, or the diffraction method; and measurement of the vol. of the fibers before and after swelling. Indirect methods are by weighing and by sp.-gr. detn. (M. and Sen, *C. A.* 33, 7575[8]). Studies of swelling-diam. relationships indicate that swelling diminishes with increase of diam., at first very rapidly, and then more slowly. Ruby K. Worner

Notes on the interpretation of jute preservation experiments with special reference to naphthenic acid derivatives, especially the copper soap. H. Courtney Bryson. *J. Textile Inst.* 30, P346–9, P349–51, P429–30(1939).—Better results were obtained with copper naphthenate than with mercury or zinc naphthenates. R. K. W.

Rotproofing of jute. H. A. Elkin and W. A. S. White. *J. Textile Inst.* 30, P340–6(1939).—See *C. A.* 34, 270[6]. Ruby K. Worner

The emulsification of [jute] batching oils. Alexander King. *J. Textile Inst.* 30, P379–86(1939).—See *C. A.* 34, 890[9]. Ruby K. Worner

Application of chlorinated rubber-tar products to jute fabrics. David D. Pratt and Roy Handley. *Bull. Rubber Growers' Assoc.* 21, 521–6(1939).—Blends of chlorinated rubber and tars (cf. *C. A.* 31, 1182[8]) can be readily emulsified, and products thus formed are suitable for impregnating jute cloth as a means of protection against water penetration and rotting. Woven jute soles impregnated by dipping in chlorinated rubber-tar blends at 80–90° become more flexible, stronger and more resistant to penetration by water. Jute thread can be satisfactorily impregnated by immersion in chlorinated rubber-tar emulsions, with formation of flexible, nonstaining yarn having good tensile strength. Jute fabrics coated with chlorinated rubber-tar blends can be used as bonding and reënforcing agents in multilayer cardboard or paper board. In this case the technique is to press the laminated materials at 50–70° for several min. under light pressure. C. C. Davis

The rinsing, brightening and oiling of flake bast. M. Münch. *Wollen- & Leinen-Ind.* 59, 305–7(1939); *Chem. Zentr.* 1939, II, 3761.—Rinsing with washing is a necessary addn. to the processing treatment for the purpose of the removal of noncelluloses from the fiber. High wetting action, emulsifying power and good adsorption of the emulsified contaminants are the prerequisites of a good washing agent. Suitable com. products are the Verapols, fat-solvent soaps (Verapol soap, Verapol N extra, Tallosan 34N) for the brightening and softening of the flake bast and Stoko oil HFP for the oiling. L. Scheflan

What is hydrophobing? Carl-Heinz Fischer. *Färber u. Chemischreiniger* 1939, 46–7; *Chem. Zentr.* 1939, II, 561–2.—Hydrophobing is the elimination in the cellulose mol. of the OH groups which produce swelling. Well-hydrophobed textiles should be stable to wet and chem. washing and dyeing. The Persistol process of the I. G. Farbenind. is described. Leopold Scheflan

Alginic acid and alginates. P. Colomb. *Teintex* 4,

653–6(1939).—Alginic acid (I), found in large quantities in brown algae, is classified among the pectic compds. I has a configuration similar to that of cellulose and pectic acid. I is insol. in all ordinary solvents but its salts are sol. in H_2O, forming very viscous solns. The viscosity of the Na and Mg salts varies with pH, having a max. viscosity at pH 7. The Al and Zn alginates dissolve in NH_4OH, forming complexes. The Ag, Hg and Pb alginates are insol. Viscometric detns. of the mol. wt. of I indicate the presence of a glucoside chain and methoxylic detns. can be used to det. the length of the chain. The alginates are used in sizing fibers and fabrics. Triethanolamine alginate aids the emulsification of linseed oil, cottonseed oil and paraffin. The pptn. of the insol. Al and Cu alginates on fibers can be used for waterproofing. S. Z.

The snares of pH control. E. Kornreich. *Dyer* **82**, 359–60(1939).—In textile processing, not only pH, but also other circumstances must be considered; e. g., the titration alky. or acidity, the influence of the treated fiber, and the method of procedure. Ruby K. Worner

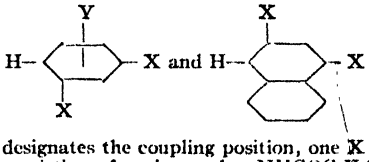
Industrial water for the textile industry. L. Schwabe. *Klepzig's Textil-Z.* **43**, 50, 52, 75–6(1940).—A discussion of the compn. and properties of the water for washing, cleaning and dyeing, methods of purification, and the use of wetting, emulsifying and chem. washing agents in place of soap. Leopold Scheflan

An improved abrasion-testing apparatus. W. Davis. *J. Textile Inst.* **30**, T133–6, T172(1939).—Results of tests on knitted fabrics are given to show the effect of a shrinkproofing process and of mixing casein fiber with wool on the resistance to abrasion. Ruby K. Worner

A low-cost water-seal fumigator. A. C. Johnson. *U. S. Dept. Agr., Bur. Entomol. Plant Quarantine* **ET-154**, 2 pp.(Jan., 1940).—The fumigator is designed for fumigating small lots of cotton samples and other commodities with either CS_2 or MeBr. K. D. Jacob

Thorough cleaning in the finishing of textiles. W. Pfluumm. *Klepzig's Textil-Z.* **43**, 90–1(1940).—The following stages in the cleaning operation are discussed: removal of sweat, grease and waxes, etc., from wool and cotton by means of soda, NH_4OH, NaOH, soap or synthetic washing agents; removal of chem. textile treating assistants, fats and sizes by means of soap, fatty alcohol sulfonates or fatty acid condensation products; dry cleaning with chem. solvents; the use of fat solvents in wet-washing operations. The recently developed com. product Lanaclarin 205 contains an alcohol sulfonate and several fat solvents differing in properties and solvent power; its use is described. Leopold Scheflan

Recent developments in textile cleaning and finishing. N. C. Cooper. *Textile Colorist* **61**, 811–13(1939).—An address. Ruby K. Worner



Aluminum triformate as a waterproofing agent. Marcel Burnand. *Teintex* **4**, 585–8(1939).—The prepn. and soly. of $(HCOO)_3Al$ at various temps. (20–70.6°) are reviewed and methods of applying it to fabrics discussed. Saverio Zuffanti

The fireproofing of fabrics. Louis Diserens. *Teintex* **4**, 671–7(1939).—D. discusses the use of NaCl, KCl, $AlBr_3$, AlF_3, $CaSO_4$, $MgSO_4$, $(NH_4)_2SO_4$, $ZnSO_4$, KNO_3, $Ca(NO_3)_2$, Na_3PO_4, K_3PO_4, $Ca_3(PO_4)_2$, $Mg_3(PO_4)_2$, Na_2HPO_4, $(NH_4)_2HPO_4$, $(NH_4)_3PO_4$, $MgNH_4PO_4$, Na_2CO_3, Na Zn and Al borates, silicates, $Al(OH)_3$ and Na stannate. Details are furnished for the use of sol. salts, insol. salts formed in the fibers, use of chlorinated rubber, and the use of cellulose esters and synthetic resins. S. Z.

Polymerization and production of new synthetics [in textile industry] (Harold) **13**. Disposition of soap in detergent operations (Colt, Snell) **27**. Catalytic action of clays and other silicate minerals and compds. on aromatic amines and phenols [adsorbents for dyes] (Eisenack) **10**. Prepn. and utilization of nitrosoamines [dyes from] (Voznesenskiĭ, Izrail'son) **10**. Benzenecarboxylic acid fluorides contg. trifluoromethyl groups [as intermediates in making dyes] (U. S. pat. 2,181,554) **10**. Assistants for use in leather and textile treatments (U. S. pat. 2,181,476) **13**.

Cotton Year Book, 1939. New York: New York Cotton Exchange. 249 pp. $2.50. Reviewed in *Rayon Textile Monthly* **21**, 130(1940).

Azo dyes. Arthur R. Murphy and Henry Jordan (to E. I. du Pont de Nemours & Co.). U. S. 2,182,347, Dec. 5. Dyes are produced which dye cotton and regenerated cellulose yellow and brown shades, etc., and which in the acid form have the general formula $Aryl—N{=}N—(Aryl_1—N{=}N—)_{n-1}—(Aryl_2—N{=}N—)_{n-1}—R$ in which Aryl is the residue after diazotization of one of a group consisting of naphthylaminemono- and -di-sulfonic acids, aminonaphtholdisulfonic acids and aminobenzenemonosulfonic acids; $Aryl_1$ and $Aryl_2$ are each from the group consisting of the residues of aminobenzene, aminobenzene substituted not more than twice by at least one of a group consisting of alkyl and alkoxy, aminobenzenemonosulfonic acids, aminobenzoylaminotoluidines, naphthylamine and naphthylaminemonosulfonic acids; each n is an integer not greater than 2; R is one of a group consisting of

where H designates the coupling position, one X is one of a group consisting of amino and $—NHCOC_6H_4Z$, where Z is one of a group consisting of amino and aminobenzoylamino and the amino groups are in one of the positions meta and para to —CO—, and the other X is $—NHCOC_6H_4Z$, Y is H or methyl; said compound having at least 2 solubilizing groups. U. S. 2,182,348 relates to products which have similar use and which comprise a plurality of mols. of the residue of an azo dye coupling component which is devoid of solubilizing groups, the residue after azotization of the Na salt of a compd. having at least two primary amine groups and azo bridges connecting the residue of the coupling component and the residue of the azotized compd., the azotizable compd. being of the formula $Aryl—N{=}N-(Aryl_1—N{=}N—)_{n-1}-(Aryl_2—N{=}N—)_{n-1}C_6H_3X_2$—2,4 in which aryl is one of a group consisting of the residue after diazotization of a naphthylaminedisulfonic acid, an aminonaphtholdisulfonic acid, a naphthylaminesulfonic acid and an aminobenzenemonosulfonic acid; the radicals $Aryl_1$ and $Aryl_2$ are each from the group consisting of the residues after diazotization and coupling of aminobenzene, aminobenzenemonosulfonic acids, aminobenzoylaminotoluene, naphthylamine, naphthylaminemonosulfonic acids, and aminobenzene substituted not more than twice by at least one of a group consisting of alkyl and alkoxy; n is an integer not greater than 2; one X is one of a group consisting of amino and $—NHCOC_6H_4Z$, where Z is one of a group consisting of amino and aminobenzoylamino and the amino groups are in one of the positions meta and para to —CO—, and the other X is $—NHCOC_6H_4Z$, the compd. having at least two solubilizing groups.

Azo dyes. Achille Conzetti (to J. R. Geigy A.-G.). U. S. 2,182,721, Dec. 5. From components such as 2′-methyl-2-aminodiphenyl ether-4-sulfonic acid, 2,8-aminonaphthol-3,6-disulfonic acid and *p*-toluenesulfonylchloride, etc., dyes are produced, of the general formula AN:NBN:NC, where A means an aromatic radical contg. at least two benzene nuclei connected by an O bridge. B means a bivalent radical from the group consisting of radicals of the benzene and naphthalene series, A and B contg. at least two sulfonic acid groups, and C means the radical of a phenol coupled in the *p*-position, bearing at the O atom the radical $—SO_2D$, where D represents an aromatic radical of the benzene series, being orange to bright red to yellowish and reddish brown dyes whose dyeings are characterized by a pure color shade, an excellent fastness to light, a good fastness to alk. and acid fulling and a very good fastness to sea water. Several examples are given.

Colloidized azo dye compositions. Moses L. Crossley, Roy H. Kienle and Alfred L. Peiker (to Calco Chemical Co.). U. S. 2,181,800, Nov. 28. A powder is prepd., suitable for use as a pigment and having as its major coloring component a water-insol. azo color, a sufficient portion of the individual color particles being coated with an autodispersibility producing "protective agent" in an amt. sufficient so that the powder as a whole possesses an autodispersibility of not less than 75% and a total dispersibility of not less than 90% with a substantial freedom from aggregates in the total dispersion visible as discrete particles by the naked eye.

Metal compounds of azo dyes. Hugo Schweitzer (to General Aniline Works). U. S. 2,182,055, Dec. 5. Numerous examples are given of dyes, giving brown and other shades, for coloring wool, *lacquers*, etc., and which include Cr or Fe compds. of azo dyes such as those formed from 1-methyl-3,4-diaminobenzene and 1-(3'-sulfophenyl)-3-methyl-5-pyrazolone and other components of generally similar character.

Sulfur dyes. Robert L. Perkins (to National Aniline & Chemical Co.). U. S. 2,182,350, Dec. 5. S dyes dyeing unmordanted cotton brown shades are obtained by the reaction of a 1,8-aminonaphthol disulfonate, an alkali metal polysulfide contg. at least 2 atoms of S for each atom of alkali metal, and an aldehyde such as formaldehyde. U. S. 2,182,351 relates to S dyes of generally like character in the production of which the aldehyde used is a furanaldehyde.

Phthalocyanine dyes. Fritz Mühlbauer (to General Aniline Works). U. S. 2,182,763, Dec. 5. By admixing phthalonitrile with sodamide dimethylaniline and adding to the mixt. thus obtained, while heating (suitably to about 70–80°) an aliphatic alc. such as amyl alc., a dye is obtained which is of greenish blue color. Several examples are given.

Reserve effects under dyeings of ester salts of leuco vat dyes. Ernst Tschan (to Durand & Huguenin A.-G.). U. S. 2,182,140, Dec. 5. A process of producing reserve effects under dyeings obtained with the use of ester salts of leuco vat dyes involves producing upon the textile material local resists against the ester salts by applying to the material locally an alk. printing paste contg. a thickening agent and dimethylbenzylphenylammonium chloride or other water-sol. compd. of the general formula $R_1R_2R_3R_4NX$, where R_1, R_2, R_3 and R_4 designate alkyl, aralkyl or aryl radicals having no sulfo or carboxy substituents, while X stands for the anion of a water-sol. salt.

Dyeing artificial fibers produced from casein. Marino Fortunato (to "Montecatini" Società, generale per l'industria mineraria e chimica). U. S. 2,182,553, Dec. 5. Artificial fibers produced from casein are prepd. for dyeing with chrome dyes by treating them with a dil. aq. mono-Na phosphate soln. (suitably at 40–50°). Cf. *C. A.* **33**, 3608[9].

Coloring materials of cellulose acetate or the like. Henry Dreyfus and Robert W. Moncrieff (to Celanese Corp. of America). U. S. 2,182,963, Dec. 12. A dyeing soln. is used formed by dissolving a vat dye such as Ciba Blue 2B in an org. base such as pyridine and reducing the vat dye in the substantial absence of water to form a leuco compd., and dilg. the resulting compn. with a neutral org. liquid such as gasoline and, after the resulting liquid is applied to the material to be dyed, the leuco compd. of the dye is oxidized on the material. U. S. 2,182,964 relates to the like use of a bath contg. an acid such as HOAc, a salt of an ester of a leuco vat dye, and an org. liquid medium such as gasoline contg. at most only a small proportion of water, with subsequent treatment of the material with an acid oxidizing agent such as an acidified aq. $K_2Cr_2O_7$ soln. to convert the dye deriv. to the parent dye.

Random dyeing apparatus for movable strands of material such as yarn. Ralph R. Janes. U. S. 2,182,752, Dec. 5. Various structural, mech. and operative details of a dye-spraying app., etc.

Condensation products. Soc. pour l'ind. chim. à Bâle, Fr. 839,529, Apr. 5, 1939. Products which are *dyes* are prepd. by causing condensing agents to act on compds. of the formula $(RNH)_nR'$, where n is 1 or more, R is a radical contg. groups by means of which the corresponding compd. may be vatted, R' is a chrysene radical, at least 1 of the C atoms of at least 1 of the R radicals and of the R', which are next to the imino group joined to the R and R', carry a H atom. The products may be treated with amines contg. groups by means of which they may be vatted, and then treated with condensing agents. Thus, di(1'-anthraquinonyl)-2,8-diaminochrysene (from dibromochrysene and 1-aminoanthraquinone) is heated in concd. H_2SO_4. The dye dyes cotton fast red shades. Other compds. which may be treated in the same way to produce dyes are described in Fr. 839,137.

Condensation products suitable for use as auxiliary agents in dyeing, or for rendering textile fibers repellent to water, or as fungicides or insecticides. Arnold Brunner (to I. G. Farbenind. A.-G.). U. S. 2,180,791, Nov. 21. By reactions such as those of paraformaldehyde and HCl with isooctylphenol or the like and further reaction of the product by heating with pyridine, compds. are obtained such as those of the general formula $C_5H_5N(Cl)CH_2C_6H_3(OH)R$ in which R represents an alkyl radical contg. at least 4 C atoms. Numerous examples with details are given.

Wetting agents for use in mercerizing, dyeing or other textile treatments, etc. Jerome Martin (to Commercial Solvents Corp.). U. S. 2,181,534, Nov. 28. Wetting agents are prepd. such as the oleic acid salts of 2-amino-2-propyl-1,3-propanediol and 2-amino-2-methyl-1,3-propanediol or other higher fatty acid salt of an aminohydroxy compd. of the structural formula: $HOCH_2C(X)(NH_2)CH(OH)Y$, where X represents H, or an alkylol or alkyl group contg. less than 4 C atoms, and Y represents H or an alkyl group, and in which the number of C atoms in X plus Y is less than 6.

Polymerization of ethyleneimines. Heinrich Ulrich and Walter Harz (to I. G. Farbenind. A.-G.). U. S. 2,182,306, Dec. 5. See Ger. 665,791 (*C. A.* **33**, 1160[7]).

Treating fibrous materials. International Latex Processes Ltd. Brit. 508,136, June 27, 1939. See Fr. 839,511 (*C. A.* **33**, 8034[2]). Brit. 508,137, June 27, 1939. See Fr. 839,512 (*C. A.* **33**, 8034[3]).

Yarn-conditioning apparatus. David E. Mills and George N. Taylor (to Universal Winding Co.). Can. 386,762, Feb. 6, 1940. Structural details.

Conditioning textile materials such as those containing cellulose acetate. Geo. W. Seymour (to Celanese Corp. of America). U. S. 2,182,323, Dec. 5. In order to give improved flexibility, etc., a conditioning fluid is used contg. a mineral oil, a softening agent such as a sulfonated oil, an aryl phosphate such as tritolyl phosphate, a higher fatty acid such as oleic acid, and an alkylolamine such as triethanolamine. Various examples are given.

Effect fabrics. Georges Rivat (to Henry Dreyfus). U. S. 2,182,321, Dec. 5. See Brit. 490,144 (*C. A.* **33**, 880[5]).

Multi-ply fabrics for making collars, etc. Thomas L. Shepherd. U. S. 2,182,882, Dec. 12. A process of making multi-ply woven fabric adapted for the manuf. of collars, cuffs, shirts, tablecloths, napkins and millinery involves immersing the plies of the fabric in a preformed cuprammonium soln. of cellulose, pressing the plies thus treated together, and treating the multi-ply woven fabric obtained in a coagulating bath to ppt. the dissolved cellulose which becomes intimately associated with the fibers of the woven fabric, and unites the plies together.

Warp sizing for rayon and other yarns. James T. Power and Ernest G. Almy. Brit. 508,068, June 22, 1939. See U. S. 2,142,801 (*C. A.* **33**, 3177[8]). Other softening agents, e. g., sulfonated or sapond. oils, may be used in addn.

Sizing rayon threads, etc. Ernst von Lippmann (to Böhme Fettchemie-G. m. b. H.). U. S. 2,182,887, Dec. 12. Treatment of rayon threads, yarns, skeins, etc., such as those of viscose rayon to effect binding in prepn. for weaving involves coating with a stable water-insol. highly acetylated saccharide having not more than 2 monosaccharide radicals in the mol. After weaving this sizing

is removed, as by treatment with water at 80–90° for an hr.

Cleaning fabrics containing a cellulose ether. Edmond H. Bucy (to Atlas Powder Co.). U. S. 2,181,691, Nov. 28. A process of cleaning and renovating a fabric having an impregnation of a water-insol. cellulose ether to protect it against water-spotting and adherence of dirt without substantially altering the flexibility, feel and appearance of the fabric and without appreciably increasing the stiffness of the fabric comprises dry-cleaning the fabric by subjecting it to the action of dry-cleaning solvents, thereby removing from the fabric the protective water-insol. cellulose ether impregnation together with adhered and imbedded dirt, then immersing the fabric in a dil. soln. of a water-insol. cellulose ether in a volatile org. solvent therefor, and allowing the volatile org. solvent to evaporate from the fabric, whereby the fibers of the fabric are impregnated with a quantity of the cellulose ether such that the fabric is protected against water-spotting and adherence of dirt, while its flexibility, feel and appearance are not substantially altered and its stiffness is not appreciably increased.

Waterproofing fibrous materials such as leather, paper or textile materials. Edward B. Bell (to Hall Laboratories, Inc.). U. S. 2,182,045, Dec. 5. The material is treated with a soln. of a salt of an amphoteric metal such as alum, a water-sol. soap such as Na oleate, an alk. solvent for the metallic soap, such as aq. NH_3, which evaps. at a temp. not harmful to the material being treated, and a mol. of dehydrated alkali metal phosphate, and the solvent is evapd. to deposit the metallic soap.

Rubberizing regenerated-cellulose rayon. Joseph I. Taylor (to North American Rayon Corp.). U. S. 2,181,538, Nov. 28. Regenerated-cellulose fibers are coated with rubber contg. a small proportion (suitably about 4–5%) of an hydroxyalkylamine such as triethanolamine to increase the adhesion of the rubber to the fibers.

Carroting animal fur fibers for felting. Anthony P. Giuliano. U. S. 2,181,884, Dec. 5. Fibers such as those of furs are treated with a soln. contg. phosphotungstic or phosphomolybdic acid, and an alkali such as NaOH to give the soln. a pH above 13 or an acid such as HNO_3 to give a pH below 3.

26—PAINTS, VARNISHES AND LACQUERS

A. H. SABIN AND CARLTON H. ROSE

Wetting as a factor in the application of paints and varnishes. W. Esmond Wornum. *Wetting and Detergency Symposium, Feb. 19-20, 1937, Brit. Sect. Intern. Soc. Leather Trades' Chem.* 97–105. **The wetting of pigments.** Geo. A. Campbell. *Ibid.* 107 16.—Reviews.
M. M. Piskur

Measurement of the resistance to corrosion of varnish and paint films on iron by the method of electrode potentials. A. M. Lazarev and E. V. Iskra. *Trudy Inst. Lakov i Krasok* 2, 191–207(1939). —The resistance to corrosion was measured on iron rods covered with two layers of the protecting agents: zinc oxide, white lead, lithopone, iron oxide, lead oxide, green lead, lead chromate, ocher, and naphthenates (all in natural drying oil). The electrolytes investigated were NaCl 3%, KCl 3%, H_3PO_4 3%, CH_3COOH 3%, Tilquist soln. (HCl 5.9% and NH_4Cl 10%) and dil. Tilquist soln. (HCl 3%, NH_4Cl 10%). The potential was measured first after 5 min., and then every hour the first day and then twice a day. The expts. are described in detail. The corrosion is greater in a flowing electrolyte than in a stationary one. A. A. B.

A new method for the determination of the adhesion of varnish and paint films. S. V. Yakubovich and E. V. Iskra. *Trudy Inst. Lakov i Krasok* 2, 156–67(1939).—A strip of film is removed by means of a sloping knife which permits obtaining a quant. characteristic of the adhesion of the nitro films to the surface of any material. This "adhesiometer" produces results which can be duplicated. The adhesion can be characterized by the effort needed to remove the film from a unit of surface. Various formulas are deduced. A. A. Boehtlingk

The shrinking of varnish and paint films. S. V. Yakubovich, E. V. Iskra and L. A. Kolosova. *Trudy Inst. Lakov i Krasok* 2, 149–56(1939).—The shrinkage of varnish and pigment films after drying was measured on a specially constructed apparatus after the removal of the films from the carrying surfaces. Films of artists oil paints and nitro films have a very extended shrinkage period after practical drying. The value of the shrinkage depends upon the material and the compn. of the films. In oil paints a max. shrinkage was observed for a definite amt. of oil. A. A. Boehtlingk

Water-miscible emulsions of paints and lacquers. K. Popov. *Maslobo˘no Zhirovoe Delo* 15, No. 5, 28–30 (1939).—Preliminary expts. in the prepn. and testing of oil-in-water paint pastes are discussed. The pastes were prepd. from dehydrated castor oil (acid no. 22, I no. 81.7, viscosity 10.2) and sardine oil boiled with 10% Mn-Ca drier to acid no. 13.7, I no. 92.6 and viscosity 1.2 (ball viscometer). The best product was obtained with oil 33.41, lithopone 39.81, dry casein 3.31, phenol 0.06 and 1.5% NH_4OH 23.41%. The pastes, when dild. with water, can be brushed but not sprayed on wood or metal surface. The coating dries in 48 hrs. In the hardness, elasticity and resistance to water the resulting films are inferior to those formed by common oil paints.
Chas. Blanc

Mural paintings in the cave temple at Sittannavasál—investigation into the method. S. Paramasivan. *Tech. Studies Field Fine Arts* 8, 82–9(1939).—A first coat of rough plaster, about 2.5 mm. thick, had the following compn.: moisture 2.14, CO_2 18.07, loss on ignition (excluding moisture and CO_2) 0.65, SiO_2 48.91, Al_2O_3 + Fe_2O_3 3.98, CaO 24.37, MgO 0.35, SO_3 0.11, undetd. (mostly alkalies) 1.39%. It received, while still wet, a lime wash to a thickness of about 0.5 mm. The pigments are identified as follows: white: lime; black: wood charcoal or lamp black; yellow and red: ochers; blue: ultramarine; green: terreverte; bluish green: mixt. of ultramarine and terre verte. A. H. Krappe

Effect of the method used in cleaning iron on the stability of the varnish-pigment film. S. V. Yakubovich and E. V. Iskra. *Trudy Inst. Lakov i Krasok* 2, 114–40(1939).—The chem. methods of cleaning metal surfaces facilitate the corrosion of surfaces subsequently covered with varnish-pigment films. The corrosion sets in with the appearance of small centers that destroy the paint, thereby creating conditions favorable for a rapid spread of the corrosion. Mechanical cleaning with brushes is considered the best method. Many expts. are described and 30 photomicrographs are reproduced. A. A. B.

An investigation into the resistance of various paints with special reference to the footing resistance of transmission poles. G. Limebeer, H. Plen and V. L. Webb. *Trans. S. African Inst. Elec. Engrs.* 30, 160(1939).—The elec. resistance of aluminum, Bitumastic, Nitrose Coal Tar, red lead and Ferrodor paints depended on the method of application and subsequent handling. Resistances of 10^3 megohms per sq. inch of surface were obtained until a breakdown voltage was reached. This was high for all paints as long as the coating remained continuous. George Papps

Luminescent pigments and paints. H. Courtney Bryson. *Oil Colour Trades J.* 96, 1181, 1183, 1235, 1237, 1239, 1242, 1285–6, 1393, 1395, 1397, 1451–3, 1502–3(1939); 97, 33–5, 82–3, 135, 137, 139(1940).—A review and discussion of theories of luminescence, properties of ZnS as regards phosphorescence and fluorescence, the manuf. of alk. earth phosphors, their heat-treatment, grinding, activators and activation, the nature

of emitted light, and the color of this light, decay rates of pigments, the influence of temp. on fluorescence and the rapid extinction of visible light known as quenching, sulfide phosphors used in luminous paints, the storage, physiol. effects, undercoatings with formulas, picking up of the undercoat, the proportion of fluorescent powder, luminous pigment pastes and finishing coats and protecting coats, the durability of luminescent paint, paint systems and their application, reflectors, ultraviolet filters and overrun lamps, used and applications of fluorescent substances, discharge and tube lighting with fluorescent pigments, screens used at the end of television cathode ray tubes, laundry inks, fluorescent glasses, visible light and the relationship of ethereal vibrations to other vibrations of longer or shorter wave length. W. H. Boynton

The relative merits of some of the more common yellow pigments in tints with white. John Lang. *Paint Varnish Production Mgr.* **19**, 328–30(1939). George Ayers

Red basic lead chromate pigments. B. A. Tsarev and A. M. Brusilovskiĭ. *Trudy Inst. Lakov i Krasok* **2**, 75–85(1939).—Pigments contg. various proportions of $PbCrO_4$, $PbSO_4$ and $PbMoO_4$ were prepd. from $PbCl_2$, K_2CrO_7, $(NH_4)_2MoO_4$, concd. H_2SO_4 and HNO_3 (80%). The following formulas are recommended: $PbCl_2$ 1000 kg., $K_2Cr_2O_7$ 363, H_2SO_4 32, $(NH_4)_2MoO_4$ 53; $PbCl_2$ 1000 kg., $K_2Cr_2O_7$ 320, Na_2SO_4 93, $(NH_4)_2MoO_4$ 53; $PbCl_2$ 1000 kg., K_2CrO_4 450, Na_2SO_4 3, $(NH_4)_2MoO_4$ 43. A wooden keg with a mechanical agitator is charged with 100 kg. $PbCl_2$, 6.3 cu. m. water is added and the mixt. is agitated for 1 hr. In another keg are dissolved 36.3 kg. $K_2Cr_2O_7$, 5.3 $(NH_4)_2MoO_4$, 3.2. H_2SO_4 (calcd. on monohydrate) and 3.2 cu. m. water, and the soln is poured during one hr. into the reactor. The mixt. is then agitated for an other hr. and the pigment obtained is washed, filter-pressed and dried. The pigment prepd. with Mo was more light stable than cinnabar and the basic pigment. Its light stability is the same as that of cadmium red, while its covering ability is 2.8 higher than that of the basic Cr pigments. The expts. are described.
A. A. Boehtlingk

The position of white lead in paint films (the "white lead phenomenon"). G. Zeidler and H. Hesse. *Paint Varnish Production Mgr.* **20**, 32, 34–6, 38–43, 54(1940).—The term "white lead phenomenon" is applied to the slightly cracked, mottled appearance of the paint film which represents a stage of weathering beyond which there is very little loss of substance for years. Both carbonate white lead and sulfate white lead paints show this phenomenon, which is largely independent of climatic conditions and of inert pigments present in the film. Paint films, contg. basic lead carbonate, after drying one week were extd. successively with petr. ether, Et_2O, C_6H_6 and tetralin. Water-sol. Pb compds., which made up 25–33% of the total Pb present, probably are in large part responsible for the "white lead phenomenon." Not all of the Pb extd. by the solvents is in the form of Pb soaps. Swelling water from paint films contg. white lead and white lead-zinc white, resp., had pH values of 5.3–5.5 and 5.4–5.65, resp., depending on the method of detn.
George Ayers

A practical hiding-power comparison of lithopone and titanium–calcium pigments in commercial flat wall paint. J. C. Thompson, Jr. *Paint Varnish Production Mgr.* **20**, 20–6(1940).—See *C. A.* **34**, 1198[3]. George Ayers

The darkening of lithopone. A. M. Brusilovskiĭ and B. A. Golynkin. *Trudy Inst. Lakov i Krasok* **2**, 251–61 (1939).—Lithopones contg. small amts. of indium darken rapidly; the presence of eosin prevents the darkening. The presence of In does not promote the appearance of yellow coloration; eosin inhibits the appearance of the yellow color. The exptl. results are plotted and tabulated.
A. A. Boehtlingk

Development of the lithopone industry in Italy. M. Sègre. *Atti X° congr. intern. chim.* **4**, 257–67(1939).
E. H.

Chalking of titanium dioxide pigmented exterior finishes. Outside house paints. R. E. Troutman and W. G. Vannoy. *Ind. Eng. Chem.* **32**, 232–7(1940).—It was found, in general agreement with the literature, that accelerated tests show poorer correlation with practical exposure conditions the greater the degree of acceleration. Increasing amts. of TiO_2 are being used in white outside house paints to obtain improved whiteness, cleanness, hiding power and durability. A newly developed type of pigment makes possible the use of TiO_2 in tinted outside house paints where the danger of excess chalking and fading have prevented any wide use of the usual TiO_2 pigments. Data and illustrations showing exposure results when this pigment is used are given.
Henry J. Wing

Gelation rates of tung and oiticica oils. D. Cannegieter. *Paint Varnish Production Mgr.* **19**, 366–8(1939); cf. *C. A.* **32**, 2766[3].—Gelation times are given for tung and oiticica oils for certain temps. between 261° and 359°, a min. occurring at approx. 350° for tung oil and at approx. 295° for oiticica oil. Increase in acid no. increases gelation time. Decompn. of tung oil starts at 350°; for oiticica oil it is evident at 295°. George Ayers

Semidrying oils in the manufacture of oil paints. A. A. Ivanova. *Trudy Inst. Lakov i Krasok* **2**, 261–5(1939).—The drying of natural drying oil after addn. of some semidrying oil plus 1% oil drier in soln. in white spirit proceeds normally if the original drying oil has normal drying properties. In the mixing of drying oils the drying of the original drying oil must be tested first and the dry residue of the oil drier must also be detd. The liquid oil drier must be taken with semidrying oils on the basis of the solid residue. The quality of films prepd. in the cold is slightly inferior to those prepared by cooking.
A. A. Boehtlingk

Semidrying oils in the manufacture of drying oils and lacquers. A. A. Ivanova. *Trudy Inst. Lakov i Krasok* **2**, 236–51(1939).—Thirty % corn oil, 20% rape-seed oil, 10% mustard-seed oil or 20% cottonseed oil can be combined with linseed oil to give mixts. of about the same drying speeds as those of natural drying oils; the hardness, elasticity, water resistance and heat stability of the films are satisfactory. Drying oils prepd. from polymerized oil mixts. dry more slowly than the unpolymerized oils, while a drying oil composed of a mixt. of oils which were individually polymerized dries still more slowly. The heat resistance is higher with the unpolymerized drying oils, and the polymerized oils are more water-stable and coagulate more rapidly. A great variety of expts. is described.
A. A. Boehtlingk

Polymerization of wood oil. R. M. Erastova, M. Oleshkovich and G. Aelanov. *Trudy Inst. Lakov i Krasok* **2**, 94–103(1939).—The manuf. of varnish can be simplified by effecting in one operation the polymerization of the wood oil and production of rosin ester, followed by evapn. of the mixt. The oil can be heat-treated only when pure to produce a standard product. The painting and technical properties of the oil are a function of the polymerization temp. The expts. are described.
A. A. Boehtlingk

The use of the oil of Oenothera biennis as a drying oil. V. Varlamov and G. Oyat'eva. *Maslobo˘no Zhirovoe Delo* **15**, No. 4, 30–1(1939).—The seeds of the plant contain 6.88% H_2O and 27.36% oil based on oven-dry seeds (extd. with petr. ether). The oil has d_{20}^{20} 0.9291, n_D^{20} 1.4801, acid no. 0.99, sapon. no. 185.7, I no. 147.68 and unsaponifiable matter 1.84%. The compn. of fat acids is: palmitic 5.6–5.7, oleic 26.4–7.6, linoleic 58.1–64.5 and linolenic acid 2.3–9.7%. Heated 2 hrs. at 150° and then treated with 3% $CaMnO_4$ drier (contg. 0.06% of active Mn), the oil dries in 24 hrs. to a sufficiently hard film. In the permeability to water and protective properties it is inferior to linseed oil films. Chas. Blanc

Production of saline drying oils from castor oil of high acidity. G. Shuraev and A. Vasil'eva. *Maslobo˘no Zhirovoe Delo* **15**, No. 5, 33(1939).—Raw castor oil is treated with 0.5% of concd. H_2SO_4 and heated at 280° for 4–5 hrs. to a required viscosity. The oil is sapond. with NaOH and the Na soap is decompd. with 10% $CaCl_2$. The Ca salts are washed free from Cl and dissolved in turpentine at 110–20°. The films become dust dry in 3 hrs.

and completely dry in 24 hrs. In their elasticity and resistance to 0.5% NaOH and H_2O they compare favorably with the coatings obtained from castor oil of low acidity. Chas. Blanc

Drying oils from polymerized raw and refined linseed oil. V. Varlamov, G. Premet and Z. Bodyazhina. *Maslobo˘no Zhirovoe Delo* **15**, No. 5, 30-2(1939).—Comparative tests indicate that polymerized raw linseed oil gives considerably stronger coating films than polymerized refined oil. Chas. Blanc

Measurement of the elasticity of varnish films by the method of residual deformation. E. Ya. Gol'denshteĭn and A. M. Lazarev. *Trudy Inst. Lakov i Krasok* **2**, 167-91(1939); cf. *C. A.* **31**, 6906[8].—A mathematical treatment of the effect of the duration of the application of a load on the value of the residual deformation, the effect of the initial deformation on the residual deformation, kinetics of the elasticity, detn. of the elasticity of various materials and a simplified testing method. A. A. B.

Pendulum method for the determination of the hardness of varnish films and the kinetics of the drying processes. A. M. Lazarev, S. Z. Ostrin and L. Matulionis. *Trudy Inst. Lakov i Krasok* **2**, 41-53(1939).—Various ball methods for the detn. of the hardness of films are described. A. A. Boehtlingk

Application of Zapon lacquers to metallic surfaces. G. Zeidler and F. Wilborn. *Paint Varnish Production Mgr.* **19**, 358-63, 373(1939); **20**, 13(1940).—A discussion of lacquers contg. highly viscous nitrocotton, which upon application to metallic surfaces are either almost invisible or have decorative effect. George Ayers

Removing agents for lacquer coatings. Freitag. *Oberflachentech.* **16**, 222(1939).- The removal of lacquer with alkalies, benzene or oil of turpentine is often costly and requires some time and mech. scraping. A new agent is recommended, methylene chloride in which paraffin is dissolved to retard evapn.; a thickener is added so that the too-liquid soln. will not run off the lacquer layer, e. g., a methylcellulose dissolved in ethyl alc. or methanol. Such remover adheres even on vertical faces, is not inflammable and acts quickly; the layers softened by it can readily be removed and the surface easily cleaned again for a firmly adhering new coat of lacquer. Also dichloroethyl ether is a good remover and does not need paraffin as addn., as it does not evap. so quickly and has a high ignition point, 131°. When mixed with alc. it can be used also as solvent for cellulose ester. M. Hartenheim

Preparation of alkyd lacquers from sunflower oil. A. Ya. Drinberg, A. S. Konoplev and E. Nosovich. *Maslobo˘no Zhirovoe Delo* **15**, No. 5, 26-8(1939). -Promising results are reported in the production of alkyd lacquers with raw sunflower oil instead of linseed oil. To glycerol, dehydrated at 140-50°, are added raw sunflower oil and 0.03% CaO catalyst and the mixt. is heated at 240° until it becomes sol. in alc. After the addn. of phthalic anhydride the heating under a current of CO_2 is continued until the "hot plate test" indicates a sufficient degree of polymerization. The alkyd resin is treated at 80-100° with the oxidized sunflower oil. The latter is prepd. by passing an air current into raw oil at 150° until the viscosity (Ostwald) increases 30 times and the oil has I no. 70, d. 0.9774 and 2.08% of HO groups. The alkyd. mixt. is then treated with Ca-Mn drier and turpentine or naphtha. Chas. Blanc

Further results of a study of primer vehicles. G. F. Beal and J. C. Konen. *Am. Paint J.* **24**, 50-5(Jan. 15, 1940); cf. *C. A.* **33**, 9019[6].—Supplemental results after 18 and 24 months exposure are given. Definite conclusions drawn from the complete investigation are: (1) In general the special primer paints show no particular advantages over 3 coats of the top paints self-primed (as regards durability). (2) Increasing the amt. of processed oil, particularly heat-bodied oils in the primer vehicle, very definitely improves the durability of the 2-coat special primer painting system. (3) The best combination seemed to be Pigment C (Ti-Ba pigment 37.5, basic carbonate white lead 37.5 and asbestine 25.0%) with Oil No. 18 used with Topcoat No. 1 (pigment 64%, vehicle 34%, with the pigment consisting of basic carbonate white lead 34.4, 35% leaded ZnO 45.6, TiO_2 10 and asbestine 10% and the vehicle consisting of linseed oil 90% and thinner and drier 10%). (4) Topcoat No. 1 is definitely superior to the other topcoats over all of the primers studied. (5) A. D. M. No. 631 or Pol-Mer-Ik refined oils give added durability to any of the primers and when used in the topcoat help to minimize the failure due to improper primer formulation. (6) A special topcoat should be designed for each special primer to obtain the best results. W. H. Boynton

Petroleum naphthas and thinners. R. D. Armsbury. *Paint Varnish Production Mgr.* **20**, 50-3(1940).—See *C. A.* **34**, 275[5]. George Ayers

Developments in lac research. H. K. Sen. *Paint Varnish Production Mgr.* **19**, 336-45(1939); cf. *C. A.* **33**, 1972[2].—Forty-nine references. George Ayers

Synthetic copals and their use in oil lacquers. A. Gamazov and M. Vostrikova. *Trudy Inst. Lakov i Krasok* **2**, 103-14(1939); cf. *C. A.* **34**, 898[9]. —Expts. in the prepn. of lacquers from albertol and rosin ester in linseed oil, with albertol and wood oil and a mixt. of wood and linseed oils, and the prepn. of a high-melting resin from a glycerol rosin ester are discussed. The physical properties of the products are tabulated. It is concluded that all synthetic copals give a harder and slightly more water-resistant film than those prepd. from rosin ester. 16 references. A. A. Boehtlingk

The preparation of alkyds and their application in nitro lacquers. P. M. Romanova and A. Chuchupal. *Trudy Inst. Lakov i Krasok* **2**, 65-75(1939). —Resins are prepd. by heating to 200-20° the mixt. and testing the gelatination by pouring the viscous mass on a plate and detg. the acid no. The products used were phthalic anhydride, glycerol and fat acids of the castor oil. In the heating of the mixt. the acidity and the duration of coagulation decrease with time, the hardness, solv. and viscosity of the soln. increase, the complete soln. of the resin in toluene takes place in not less than 1.5-2.0 hrs. from the time the temp. was raised to 210-15°. The softest resins were obtained from 65% of the fat acids, 22% phthalic anhydride, the hardness increasing with the decrease in the proportion of the fat acids. The alkyd films are more elastic than resin ester films in nitro lacquers. Nitro lacquers prepd. from resins contg. fat acids did not differ from those contg. triglycerides. Thus fat acids may be substituted by crude castor oil. The expts are described in detail. A. A. Boehtlingk

Newer uses for shellac. Wm. Howlett Gardner. *Chem. Industries* **45**, 685-8(1939); cf. *C. A.* **33**, 6071[7]; **34**, 191[1]. E. H.

Dowtherm for heating and cooling resin kettles. D. K. Dean. *Paint Varnish Production Mgr.* **19**, 352, 354-6, 373(1939). -See *C. A.* **33**, 5543[6]. George Ayers

Reagent-resistance tests on finishes. G. G. Sward and H. S. Klund. *Natl. Paint, Varnish Lacquer Assoc., Sci. Sect., Circ.* **570**, 7-13(1939). —Coatings were exam'd. for their resistance to lemon juice, 50% EtOH, whiskey, whiskey of highball strength, beer, 3% aq. NaOH, 50% aq. HCl and toluene. The reagent was applied as a paste mixed with $BaSO_4$. Reduction in gloss of the finish after standing in contact with the paste was measured. Resistance to HCl was best in reduced phenolics and alkyds and was improved by baking. Resistance to NaOH was best in straight phenolics and in 25-gal. tung oil-V-resin varnish. Air-dried finishes and baked alkyds were badly affected. Lemon juice and beer were almost without effect. Baked alkyds resisted toluene and baked natural-resin varnishes resisted alc. beverages. H. M. Stark

---

Extn. of oil from *Lallemantia* seeds (Lesyuis) **27**. Detection of radioactivity in works of art (Evans, *et al.*) **3**. Corrosion of steels and protection by means of oily paints (Bancelin) **9**. Tobacco-seed oils [in prepn. of varnishes] (Curelici) **27**. Japanese lacquer mixed with phenolic and alkyd resins (Simizu, Inai) **13**. Decompn. of titanite minerals with HCl [to get pigment] (Brusilovskiĭ, Staro-

sel'skiĭ) 18. Internal lacquering of tinplate containers for foods (Lynch, Kefford) 12. Sepn. of satd. acids from vegetable oils by freezing [solid fraction used in alkyd lacquers] (Drinberg, Zhebrovskiĭ) 27. Japanese lacquer mixed with alkyd resin and asphalt (Simizu, Inai) 13. Interpolymerization of fumaric esters and isobutylene [products for making lacquers] (U. S. pat. 2,182,316) 13. Terpene ethers [as solvents or plasticizers in printing inks] (U. S. pat. 2,182,826) 10.

Heaton, Noël: Outlines of Paint Technology. 2nd ed. London: C. Griffin and Co., Ltd. 400 pp. 25s.

Stewart, Jeffrey R.: The National Paint Dictionary. Alexandria, Va.: Stewart Research Laboratories. 154 pp. $5.00. Reviewed in *Chem. Met. Eng.* **47**, 139 (1940).

Paint for ship bottoms, etc. Giuseppe Capurro. U. S. 2,182,840, Dec. 12. An anticorrosive, nonfouling compn. is prepd. from coal tar 36, S 28, resin 14, Paris green 3, and benzene 19%, mixed and boiled not over 2 hrs.

Red lead. James O. Johnstone (to Glidden Co.). U. S. 2,182,436, Dec. 5. A livering red lead is rendered substantially nonlivering with acid paint vehicles by subjection to the action of CO_2 (suitably at room temp.) to convert active PbO present into nonreactive Pb carbonates.

Titanium dioxide. Benjamin W. Allan and L'Roche G. Bousquet (to American Zirconium Corp.). U. S. 2,182,420, Dec. 5. A method of making TiO_2 comprises digesting ilmenite with H_2SO_4, treating the reaction mass to obtain a clarified soln. contg. more than 100 grams per l. of TiO_2 and a factor of acidity above 70%, and contg. all the sulfate derived from the ilmenite, adjusting the factor of acidity to from 20 70% by adding a substantial amt. of a basic compd. which forms a sol. sulfate, then hydrolyzing the so-prepd. hydrolysis soln., washing and calcining the ppt.

Titanium dioxide pigments. Robert W. Ancrum and Assur G. Oppegaard (to National Lead Co.). Can. 386,-623, Jan. 30, 1940. To a mineral acid soln. of Ti is added an Sb oxide (or a compd. that yields Sb oxide on calcination) in an amt. equiv. to 0.1–55.0% of Sb based on the Ti content of the soln., calcd. as TiO_2, the soln. is subjected to hydrolytic decompn., the ppt. is filtered, washed and calcined in the absence of amts. of alkali metal compds. exceeding about 2% at 900–1100° for sufficient time to develop the TiO_2 pigment properties.

Zinc sulfide pigment. John H. Calbeck (to American Zinc, Lead & Smelting Co.). U. S. 2,181,651, Nov. 28. A pptd. ZnS pigment is washed with water to remove some of the impurities, the ppt. and remaining impurities are then treated with a base such as CaO or $Mg(OH)_2$ and resulting reaction products are washed from the ppt. with water, and the washed ppt. is then calcined.

Metal containers suitable for shipping and storing white lead and similar materials. Harry G. Mann and Wm. F. Kinney (to American Can Co.). U. S. 2,182,-813, Dec. 12. Various structural details.

Purifying wood rosin. Robert E. Price (to Crosby Naval Stores, Inc.). U. S. 2,181,791, Nov. 28. A process for purifying wood rosin involves dissolving it in a solvent such as petroleum naphtha and bringing the resulting soln. into contact with a Mg silicate having a mol. ratio of MgO SiO_2 between 1:1.25 and 1.1.60, sepg. the soln. from the Mg silicate, recovering the purified rosin from the soln. by distn., washing the Mg silicate after the sepn., first with petroleum naphtha, then with alc., finally with the rosin solvent, and then again bringing the washed Mg silicate into contact with a further soln. of impure rosin.

27— FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

The fat of land crabs. (Seychelles Islands.) T. P. Hilditch and K. S. Murti. *J. Soc. Chem. Ind.* **58**, 351–3(1939). - The depot fat of the land crabs of the Seychelles Islands contains the following acids: octoic 1.5, decoic 5.3, lauric 47.5, myristic 19.0, palmitic 13.1, stearic 1.7, tetradecenoic 0.7, hexadecenoic 2.3, oleic 5.3, linoleic 1.5, and unsatd. C_{20-22} acids 2.2%. It contains 66.3% of fully satd. glycerides, the component acids of which include octoic 3.2, decoic 7.1, lauric 54.8, myristic 20.5, palmitic 12.7 and stearic 1.7%. This unusual compn. is explicable since *Birgus latro*, L., the coconut crab, is known to feed on coconuts. The depot fat is thus composed largely of glycerides from ingested coconut fat while the remaining part of the fat includes the acids typical of a marine animal fat, unsatd. C_{18} acids and unsatd. C_{20-22} acids. E. Scherubel

Component fatty acids and glycerides of some Myristica fats. D. Atherton and M. L. Meara. *J. Soc. Chem. Ind.* **58**, 353–7(1939).—The component fat acids and glycerides of *Virola* and *Pycnanthus kombo* kernel fats were detd. as follows: *Virola:* decoic 0.5, lauric 14.8, myristic 72.5, palmitic 4.9, oleic 6.3 and unsaponifiable 1.0%. *Pycnanthus kombo:* lauric 5.4, myristic 60.8, palmitic 3.6, tetradecenoic 23.4, oleic 5.6 and unsaponifiable 1.2%. The corresponding component glycerides for *Virola* fat are: myristin 43.0, laurodimyristin 31.0, oleolauromyristin 12.0 and lauromyristopalmitin 10.0%. The component glycerides for *P. kombo* fat are: tetradecenodimyristin 33.0, trimyristin 24.0 and laurodimyristin 17% with smaller amts. of myristoditetradecenoin, laurotetradecenomyristin and oleotetradecenomyristin. The presence of tetradecenoic acid in this fat has been previously found only in fish and whale oils and in small amts. in butterfat. E. Scherubel

Dilatometer measurement method as a useful tool in fat study. C. A. Coffey and H. T. Spannuth. *Oil and Soap* **17**, 41–2(1940).—The app. used consists of a 25-ml. glass cylinder to one end of which there was fused a 50-cm. calibrated capillary with bore capacity of 280 mm./cc. H_2O. A metric scale is attached to the capillary arm; and a glass stopcock is fused to the other end. It was sought to det. if fat differences, as reflected in component fat acid differences, could be correlated with he differences in vol. expansion experienced by the correspondng glycerides for a definite temp. range. Data are tabulated showing that dilatometer readings for a hydrogenated fat are reproducible within ±0.1 cc. Other tabulated data show that the more satd. fats have greater vol. changes with temp. than unsatd. fats. In general the fat acid types having the greatest vol. change with temp. are first, satd.; 2nd "iso-oleic;" 3rd, oleic; and least in effect is linoleic acid. E. Scherubel

Fatty acids and glycerides of the seed fats of Allanblackia floribunda and Allanblackia parviflora. M. L. Meara and Y. A. H. Zaky. *J. Soc. Chem. Ind.* **59**, 25–6 (1940).—*Allanblackia floribunda* is a member of the Guttiferae family and occurs in Nigeria while *A. parviflora* also of the same family occurs in the Gold Coast. The component fat acids of the former have been found to be palmitic 3.2, stearic 56.8, arachidic 0.2, oleic 39.4 and linoleic 0.4% (mol.); the component glycerides are chiefly oleodistearin approx. 76, with stearodiolein 15.5 and about 5% of oleopalmitostearin. The component fat acids of *Allanblackia parviflora* were found to be myristic 1.8, palmitic 2.5, stearic 51.6, arachidic 0.2 and oleic 43.9% (mol.). In comparison the total amt. of C_{18} acids is almost the same, but with *A. parviflora* the larger amt. of oleic acid is accompanied by less stearic acid. This is further reflected in the major component glycerides which consist of approx. 60 oleodistearin, 26–9 stearodiolein and 6–9% of oleopalmitostearin. E. Scherubel

Hardening of fatty oil with quincuncial component

catalyzers. Sei-iti Ueno and Takehide Suzukawa. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 350–1(1939); cf. *C. A.* **33**, 1529[9].—Five-component catalytic mixts. (in the proportions 40:30:15:10:5), formed by co-pptn. of 5 metallic salts in the presence of kieselguhr and reduction by H in the usual manner, were added to soybean oil in the proportion of 0.3 g. metal to 100 g. of oil, and the oil-catalyst mixt. was heated to 180° under 10 atm. H pressure, after which the H pressure was raised to 30–50 atm. for ½ to 1 hr. In the catalytic system Ni–Cu–Co–Mn the addn. of Cr, Mg, Zn or Pb as the fifth metal markedly increases catalytic activity, Fe retards it, while Ca or Ba has no pronounced influence. In the catalytic system Ni–Cu–Co–Zn the addn. of Pb, Ca or Fe as a fifth metal promoted catalytic activity, while Mn retarded it. Catalysts contg. Ni-Cu-Co-Mn and a fifth element are more active, in general, than those contg. Ni-Cu-Co-Zn and the fifth element. Ni-Cu-Mg-Co catalysts contg. Mn, Cr, Pb, Ba, Ca, Zn or Fe as a fifth metal were not as active as the 4-component catalyst system. George Ayers

Regeneration of spent (nickel) catalyst by the alkaline method. N. Kaminskiĭ and E. Chufarovskaya. *Maslobo˘ino Zhirovoe Delo* **15**, No. 4, 10–13(1939).—In the modified method of Etinburg, Vengerova and Gol'dstein (*C. A.* **30**, 3950[8]), after the removal of fat, the catalyst mixt. is treated with dil. H_2SO_4 instead of a NaClO soln. and then reactivated by the usual method. Chas. Blanc

Determination of hydrogen number of hardened oil. G. Zhabrova. *Maslobo˘ino Zhirovoe Delo* **15**, No. 5, 34–7 (1939).—In the detn. of the degree of unsatn. in hardened fat mixts. by the method of Kaufmann and Baltes (*C. A.* **32**, 1958[6]), more consistent results are obtained with the use of Pt pptd. on $BaSO_4$. Detailed procedure and diagrams of app. are given. Chas. Blanc

Wijs iodine numbers for conjugated double bonds—influence of sample—reagent ratio. Wm. C. Forbes and Harvey A. Neville. *Ind. Eng. Chem., Anal. Ed.* **12**, 72–4(1940).—Iodine nos. obtained by the Wijs method for systems contg. conjugated double bonds are strongly influenced by the excess amt. of reagent present. Data are presented to show this effect for the conjugated systems 9,11-linoleic acid, tung oil and dehydrated castor oil. Contrasting data show that the excess of reagent is of slight importance for the isolated systems 9, 12-linoleic acid and 9, 12, 15-linolenic acid and for raw castor oil. E. Scherubel

Relation between the iodine values and refractive indexes. III. Hardened safflower oil. R. V. Joglekar and S. K. K. Jatkar. *J. Indian Inst. Sci.* **22A**, 219–23 (1939).—The relationship between the I no. and n of safflower oil hardened by the continuous process is given by the expression $n^{25°} = 1.4463 + 1.03 \times 10^{-4} \times (\text{I no.}) + 7.3 \times 10^{-8}$ (I no.). E. Scherubel

Separation of saturated acids from vegetable oils by freezing. A. Ya. Drinberg and V. V. Zhebrovskiĭ. *Org. Chem. Ind.* (U. S. S. R.) **6**, 327(1939).—Free acids are sepd. from cottonseed, sunflower and soybean oils by freezing at −20° to −38° for 1.5–24 hrs. The mixed acids are then dissolved in naphtha and chilled at −20° to sep. of solid (satd.) acids and liquid (unsatd.) acids. The solid fraction can be used in *soap making* and the liquid fraction in the production of *alkyd lacquers*. The work is being continued. Chas. Blanc

Expression of vegetable oils. IV. Expression of rapeseed oil. Eugene C. Koo. *J. Chem. Eng. China* **5**, 69–73(1938).—Rapeseed from Szechuan, contg. originally 2.32% moisture and 41.20% oil, was ground to 20–40 mesh and its moisture content brought up to 6.9% by cooking and steaming. Four hundred g. of this meal was used for each run in the form of 2 cakes pressed to form in a lab. hydraulic press. The effects of pressure, temp. and duration of pressing are investigated, keeping 2 of these 3 variables const. and varying the third one in each series of expts. The pressure used varies from 1500 to 3500 lb./sq. in., temp. from 25° to 70° and time from 1 to 5 hrs. From the results of these expts., the following equation is deduced to represent the expression of rapeseed oil quantitatively: $\overline{W}^2 = 0.0523\ (\sqrt[3]{\theta}/\sqrt[3]{\mu/\rho})$ where W is the wt. % (wet basis) of the rapeseed oil expressed; P, pressure in lbs. per sq. in.; θ, duration of pressing in hrs. and μ/ρ, kinematic viscosity of the oil corresponding to the press temp. in strokes. C. L. Tseng

Effect of refining on the digestibility of edible oils and fats. F. G. T. Menezes and B. N. Banerjee. *J. Indian Inst. Sci.* **22A**, 203–17(1939).—The rates of digestion of different oils are different after refining. Clarification, neutralization and decolorization do not affect the digestibility of coconut oil, but peanut and cottonseed are affected. Gingli oil improves on refining; and the deodorized oil, when activated, gave the best results. Refining processes retard the digestibility of oils more or less as the natural activator is generally lost. The vitamin potency of oils in India does not hold well. Generally, the retardation of digestion and instability or loss of vitamin A in oils or fats on refining treatment run parallel. Graphs and tables are given. E. Scherubel

Specific behavior of olive and olive-seed oils. G. Karagunis and D. Solmos. *Chim. Chronika* **10–12**, 218–23(1938)(in Greek).—By means of a combination of absorption and fluorescence methods a color reaction is obtained which permits detections with sesame or cottonseed oils up to 10%. Lucien Y. Dyrenforth

A chronology of cottonseed technology. Lawrence W. Bass and H. S. Olcott. *News Ed. (Am. Chem. Soc.)* **18**, 139–42(1940).—A record of development covering the time span from 1607 through 1939. E. J. C.

Cottonseed chemistry. John R. Erwin. *Wisconsin Engr.* **44**, 55–6(1940).—The extn. of vegetable oils by solvents is discussed. Ann Nicholson Hird

Forepressing of cottonseed. I. Morozov. *Maslobo˘ino Zhirovoe Delo* **15**, No. 5, 7–11(1939).—A method of expelling oil from whole and crushed cottonseed with subsequent extn. of the press cake is discussed chiefly in the light of American practice. The procedure is described in detail and diagrams are given. Chas. Blanc

The effect of processing methods on the quality of linseed oil. A. M. Goldovskiĭ. *Maslobo˘ino Zhirovoe Delo* **15**, No. 4, 4–5(1939).—Tentative lab. tests showed that the ash content and color intensity of linseed oil increase with greater temps. of pressing and extg. with benzine. Under all comparable conditions whole seeds give a better product than crushed seeds. C. Blanc

Utilization of the by-products in the dehydration of castor oil. I. T. Osnos and I. I. Golovistikov. *Maslobo˘ino Zhirovoe Delo* **15**, No. 4, 27–30(1939); cf. *C. A.* **33**, 5681[2].—The dehydration of castor oil at 280° and 100 mm. for 12–13 hrs. in the presence of 0.5% catalyst (0.19% MnO_2 + 0.31% PbO) gave 88.2–89.2% of dry oil and 10.7% of a condensate. The latter on distn. with steam gave 73.7% *enanthaldehyde* and 20.4% of a distillate contg. 40% of *undecylinic acid*, or 3.37% and 0.5%, resp., on the wt. of raw castor oil. Chas. Blanc

New process for the extraction of castor seed or cakes with industrial alcohol. Nitya Gopal Chatterjee. *Ind. & News Ed., J. Indian Chem. Soc.* **2**, 171–7(1939). The advantages of extg. castor seed with alc. instead of expressing the seed in a hydraulic press are: completely decorticated seed can be used and all of the oil obtained as No. 1 oil; the yield is 4% greater; the N content of the cake is 25% higher; the cost of manuf. is less; the recurring expenses such as replacement of press bags or machinery parts are eliminated. E. Scherubel

Reworking of crushed castor beans on the worm-screw press. A. I. Skipin, M. Zhdan-Pushkin, A. Zarabyan and I. Engel. *Maslobo˘ino Zhirovoe Delo* **15**, No. 4, 6–9 (1939).—Certain advantages of final expression of oil from forepan castor-bean oil meal with the aid of worm-screw press are discussed. The procedure is described and diagrams of app. are given. Chas. Blanc

Technology of drying of sunflower seeds. S. Kucherov and E. Plyushkina. *Maslobo˘ino Zhirovoe Delo* **15**, No. 5, 11–14(1939).—The experience of the Poltava mill shows

that the best results are obtained by drying the seeds to 6.5–7.5% of moisture content. Chas. Blanc

Pressing sunflower-seed meal without the use of filter cloth. M. Pitkevich. *Maslobolno Zhirovoe Delo* 15, No. 5, 11–14(1939).—Construction and operation details. Chas. Blanc

Smoke, flash and fire points of soybean and other vegetable oils. S. B. Detwiler, Jr., and K. S. Markley. *Oil and Soap* 17, 39–40(1940).—The av. values of representative soybean oils with respect to smoke, flash and fire points as detd. by the Cleveland open-cup method were as follows:

Type of oil	No. of detns. averaged	Av. flash point	Av. fire point
Crude expeller	4	300°	351°
Crude solvent extd.	5	316°	355°
Refined	11	329°	361°

E. Scherubel

Extraction of oil from Lallemantia seeds with the aid of worm-screw press. A. A. Lesyuis. *Maslobolno Zhirovoe Delo* 15, No. 4, 9–10(1939); cf. *C. A.* 33, 5689⁹.—A good grade of stand oil can be obtained from the whole seeds or roasted seedmeal of *Lallemantia iberica* by extn. in the worm-screw press and refining with 20% excess of 10°Bé. NaOH. The oil can be decolorized with charcoal or by heating at 200–50°. Chas. Blanc

Tobacco-seed oils. Gheorghe Curelici. *Bul. cultivării fermentării Tutunului* 28, 469–500(1939).—Botanical and chem. data, are given, with 7 lab. analyses of tobacco seed, data on the technology of seed-oil extn. with special reference to the prepn. of *varnishes*, a survey of the secondary products and a summary of the methods of phys. and chem. analysis of tobacco-seed oil. The installation of a plant for the hydrogenation of the oil, with a capacity of 5000 l. per hr., is described. 15 references. A. H. Krappe

Chinese turtle oils. Tyūta Hata and Masaiti Huzikawa. *J. Soc. Chem. Ind., Japan* 42, Suppl. binding 329(1939); cf. *C. A.* 33, 6028¹.—Yields of Chinese turtle oil (from *Ocadia sinensis* Gray, the most common turtle in Formosa) from the body, liver and ovary were 6.4%, 19.5% and 2.5%, resp. Tests on these respective oils gave: d_4^{25} 0.9114, 0.9035, (d_4^{40}) 0.9418; n_D 1.4648, 1.4618, (n_D^{40}) 1.4722; acid value 0.52, 10.12, 7.58; sapon. value 202.10, 203.32, 198.88; I value 93.27, 78.98, 102.53; unsaponifiable matter 2.8%, 10.7%, 6.2%. Only the liver oil gave the color reaction for vitamin A. Myristic, palmitic, stearic, zoomaric and oleic acids and a small quant. of highly unsatd. acid and eicosadienic acid were identified in the oils. The unsapon. matter consists chiefly of cholesterol, hexadecenol and octadecenol. George Ayers

Bamboo leaf waxes. I. The leaf wax of "nemagari-daké," Sasa paniculata. Mitumaru Tuzimoto. *J. Soc. Chem. Ind., Japan* 42, Suppl. binding 396(1939).—The leaves of "nemagari-daké," *Sasa paniculata* Makino et Shibata (a variety of bamboo which grows abundantly in the mountainous districts of Central Japan), upon extn. with petr. ether, yields approx. 1% of crude wax which, after treatment with animal charcoal in EtOAc, gave a brownish yellow hard brittle wax having the following properties: d_4^{25} 0.961; m. 79–80°; acid value 14.5; sapon. value 43.4; Wijs I value 7.8; and unsaponifiable matter approx. 65%. The fat acids sepd. from the wax made up a brownish yellow, hard solid, m. 81–2° and had a neutralization value of 121.8 and I value of 4.7. The unsaponifiable matter was a brownish yellow solid, m. approx. 87–8° and had an I value of 12.7 and an Ac value of 58.9 and contained no appreciable amt. of sterols. Melissic acid and myricyl alc. were identified in the wax: satd. acids such as montanic and cerotic acids are possibly also present. The wax, in general, resembles carnauba wax. George Ayers

Esters in distilled glycerol. V. Loginov and G. Kuznetsova. *Maslobolno Zhirovoe Delo* 15, No. 5, 15–17(1939).—The source of formation of esters in glycerol is the presence of nonvolatile org. residues in the sapon. mixt. The method of adding an excess of $Ca(OH)_2$ to raw glycerol or the sapon. mixt. reduces but little the content of esters. The best results were obtained with the addn. of 2–3% Fe filings at 80° and a slight excess of $Ca(OH)_2$ at 95–100°. The filtered soln. is freed from excess $Ca(OH)_2$ by passing CO_2 or air and filtering. The method is based on the sapon. of esters and greater adsorptive power of $Fe(OH)_3$ formed in the reaction. Chas. Blanc

Formation of esters and acrolein in the distillation of glycerol. A. A. Bag, T. P. Egupov, Yu. Orlova and L. Yurkov. *Maslobolno Zhirovoe Delo* 15, No. 4, 13–16 (1939).—The redistn. of neutral glycerol fails to decrease the contents of esters and acrolein in the finished product. The simultaneous formation of esters and acrolein is favored by high temps. and to a certain extent by a prolonged duration of heating in the process of vacuum distn. with steam. The addn. of excess $Ca(OH)_2$ in the neutralization of the sapon. mixt. reduces the side reactions during the distn. The addn. of alkalies to raw glycerol before the distn. does not retard the formation of esters and acrolein. Redistn. with the addn. of alkali produces the desired effect. Chas. Blanc

The solubility of organic substances in aqueous soap solutions. A. S. C. Lawrence. *Wetting and Detergency Symposium*, Feb. 19–20, 1937, *Brit. Sect. Intern. Soc. Leather Trades' Chem.* 203–7; cf. *C. A.* 31, 6496⁴.—A review. M. M. Piskur

Volumetric determination of unsaponified fat in soap by the Spasskiĭ method. M. Smolina. *Maslobolno Zhirovoe Delo* 15, No. 5, 37(1939).—It is shown that the Spasskiĭ method (*C. A.* 30, 1250⁶) gives low values as compared with the Spitz-Hönig method. Chas. Blanc

The use of electrolytes in soaps. F. Nevolin. *Maslobolno Zhirovoe Delo* 15, No. 4, 18–19(1939).—The advantages of addns. of various electrolytes (alkali carbonates, silicates and phosphates) to laundry soaps are discussed in the light of American and German practices. Chas. Blanc

Disposition of soap in detergent operations. E. W. Colt and C. V. Snell. *Oil and Soap* 17, 33–8(1940).—Tests made show that the adsorption of soap from 0.100% soap soln. is 19.5, 7.6, 11.1 and 60.0% for cotton, rayon, silk and wool, resp. To det. what effect the normal CO_2 content of the air might have on the pH of soap solns. air was passed through a NaOH soln. to remove CO_2, then through H_2O to sat. the air and then through 150 ml. of a 0.100% soap soln. The pH, concn. of soap in soln. and in the foam were detd. after each test. A similar test was made with air not scrubbed free from CO_2. The data reveals that the CO_2 present the pH value of the foam but not of the soln. was diminished. With no CO_2 present in the air no change in pH occurred in soln. or foam. When the foam was evapd. to dryness at 110° and redissolved in CO_2-free H_2O to the same concn. the same pH as in the original soln. was observed. To det. the effect of a fabric load a similar expt. was made with 15 g. of cotton sheeting using CO_2-free air. The pH value was lowered in the soln. proper and the interface of the foam. The adsorption of soap by cotton from a soln. of detergent comprising 70% soap and 30% alk. salt is shown in the following table:

Solution	% of total detergent adsorbed	% of initial soap adsorbed
0.07% soap	21.2	21.2
0.07% soap + 0.03% Na_3PO_4	15.0	21.4
0.07% soap + 0.03% Na_2CO_3	15.0	21.8
0.07% soap + 0.03% tetra Na pyrophosphate	15.5	23.3
0.07% soap + 0.03% buffered Na hexametaphosphate	16.1	23.0
0.07% soap + 0.03% Na silicate-N	16.8	23.8
0.07% soap + 0.03% Neutral soda	16.6	24.0
0.07% soap + 0.03% Na metasilicate	17.0	24.4

No alk. salt was adsorbed. It was also found that at 0.04% soap concn. the presence of 30% Na_2CO_3 in the detergent formula increases the percentage of soap adsorbed compared to pure soap. The presence of 60%

Na_2CO_3 decreases the percentage of soap adsorbed compared to pure soap. At 0.08% soap concn. the presence of 30% Na_2CO_3 in the detergent formula increases the percentage of actual soap adsorbed. At 0.12% soap concn. the presence of 30% Na_2CO_3 decreases the percentage of actual soap adsorbed. The fact that addns. of Na_2CO_3 in increasing amts. to a fixed concn. of soap impairs detergency would indicate that the effect of this must be due, not to the prevention of hydrolysis, but to the shifting of the form of the soap in the direction of undissocd. crystalloid or to the micelle form, but since a fabric load results in selective alkali adsorption in amts. greater than the adsorption of fat acid radicals, and detergency with a substantial load is benefited by Na_2CO_3, the indications would be that acid soap, in substantial amts. at least, is objectionable. E. Scherubel

The necessity of revising the standards of washing materials. D. Rozhdestvenskii. *Maslobo'no Zhirovoe Delo* **15**, No. 4, 16–18(1939).—A discussion with recommendations for the improved production and standardization of toilet and laundry bar and powd. soaps in accord with the best American and English practices. Chas. Blanc

Refining animal or vegetable oils such as soybean oil, peanut oil, or cocoa butter. Olof E. Fröding (to De Laval Separator Co.). U. S. 2,181,563, Nov. 28. An arrangement of app. is described, and a process, which comprises refining vegetable and animal oils wherein the oil is mixed with a saponifying agent to effect saponification of fatty acids contained in the oil and heated through a considerable range of temp. and the oil then sepd. from undissolved soaps, and interposing between the mixing and heating procedure and the sepn. of the oil from the soaps a cooling step in which the mixt. is cooled through the major part of the temp. range through which it was heated to increase the proportion of undissolved soaps before sepn. and substantially reduce the proportion of soaps in the subsequently sepd. oil.

Refining animal and vegetable oils. Benjamin Clayton, Walter B. Kerrick, Henry M. Stadt and Benjamin H. Thurman (to Refining, Inc.). U. S. 2,182,755, Dec. 5. An arrangement of app. is described, and a method for quick and continuous refining of animal and vegetable oils contg. free fatty acids which involves mixing the oil with a refining reagent such as NaOH soln. capable of acting upon the impurities in the oil to form foots, sepg. the foots substantially as quickly as they are formed by centrifugal action assisted by heating effected by the preheating of at least one of the materials before admixt. with each other (any prolonged contact of the oil and refining agent being avoided). Cf. *C. A.* **33**, 4808[4].

Reconstructing glyceride oils. Geo. Barsky (to Wecoline Products, Inc.). U. S. 2,182,332, Dec. 5. A method adapted for obtaining products of higher m. p. involves treating crude bleached cocoanut oil, butter or castor oil or other glyceride oils having in combination lower and higher fatty acids of from 6 to 18 C atoms to alter the phys. and chem. characteristics of the oils and comprises providing a mixt. of the oil and a free fatty acid having at least 2 more C atoms than the lowest fatty acid to be displaced but not over 18 C atoms, and heating the mixt. to a sufficiently high temp. whereby a reaction takes place freeing the lower fatty acids which are replaced by the added fatty acid and removing the fatty acids so freed. Several examples with details are given.

Recovery of glycerol from soap lyes. Ralph H. Potts and Edwin W. Colt (to Armour and Co.). U. S. 2,182,179, Dec. 5. An arrangement of app. is described, and a process which involves acidifying a soap lye with HCl to give it a pH of about 3–4, extg. the acidified lye with a water-insol. triglyceride or fatty acid having a higher mol. wt than that of fatty acids on the acidified material, neutralizing the acidified extd. lye, and recovering glycerol from it.

Obtaining phosphatides from soap stock. Benjamin H. Thurman (to Refining, Inc.). U. S. 2,182,767, Dec. 5. Soap stock resulting from the alkali refining of phosphatide-contg. vegetable oils such as cottonseed oil, etc., and contg. phosphatides and soap, is treated with a selective solvent such as "petroleum ether," ethyl ether, benzene, ethylene dichloride, trichloroethylene, CCl_4, acetone or MeOAc for dissolving one or the other of the assocd. materials to effect their sepn. from each other. Several examples with details are given.

Zerban

Deliming of thin sugar juices by chemical means and its economy. G. Radbruch. *Deut. Zuckerind.* **64**, 953–4, 965–6, 977–8(1939); cf. *C. A.* **33**, 9027[8].—Dusarit (zeolite) completely delimed and partially decolorized thin juices. W. W. Binkley

Speed of carbonation. M. K. Smolenski and M. T. Pietrzykowski. *Sucr. belge* **59**, 101–8, 122–32, 141–6 (1939).—The speed of carbonation of solns. of NaOH and of $Ca(OH)_2$ is increased by raising the temp., vigorous stirring, and increasing the depth of the solns. Rapid introduction of CO_2 and its increase in concn. decrease its effectiveness. There is an optimum concn. of sugar (0.5 mol./l.) for max. speed of carbonation of $Ca(OH)_2$ solns. Liming with cold, dry lime causes a slight increase in speed of carbonation as compared with the use of hot milk of lime. CO does not affect the speed. W. W. B.

Review of the reworking of different sugar-factory waste waters and the processes concerned. Gottfried Mück. *Deut. Zuckerind.* **64**, 1041–2(1939). W. W. B.

Removal of lead in maple sirup by means of base-exchange material. C. O. Willits and C. J. Tressler, Jr. *Food Research* **4**, 461–8(1939); cf. *C. A.* **33**, 7916[9].—Ca Zeo-Karb (a com. zeolite) will remove Pb from maple sap through base exchange. Between 5 and 60° the amt. of Pb removed is independent of the temp. The amt. of Pb removed is dependent on the contact time. Using a contact time of 1 min. the Pb concns. in maple sirup can be reduced from 36 p. p. m. to less than 1 p. p. m. The percolating of maple sap through the zeolite does not alter the ash values of maple sirup prepd. from the sap. C. R. Fellers

How to remove lead from maple sirup. Augustus Conlin. *Food Ind.* **12**, 52–3(1940).—The Pb in soln. is pptd. by Na_2HPO_4. Normally 0.05% of this salt

sufficient to lower the Pb content to less than 1 p. p. m. The sirup is heated to 72–80° before adding the Na_2HPO_4 with const. agitation. After 30 min. the sirup can be filtered with the help of a good filter aid. Cf. *C. A.* **33**, 7916⁹. C. R. Fellers

29—LEATHER AND GLUE

HENRY B. MERRILL

Studies on the tannin materials in Taiwan. I-II. The chemical composition of the barks from Acacia cofusa, Merr. and preparation of their tannin extracts. Saiti Tasaki. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 321–2(1939).—Fourteen samples of bark from 4 localities were analyzed to det. the water content, reducing and nonreducing sugar contents, pH value and the percentages (dried-sample basis) of tannins, nontannins and insol. matter. The tannins belong to the catecholtannin group. Analyses of a no. of bark exts. are also included. George Ayers

Characteristics that determine tanning power. A. Deforge. *Halle aux cuirs* **1939**, 169–74; cf. *C. A.* **33**, 4074⁴.—For both Cr and vegetable tanning compds., tanning power (i. e., astringence) passes through a max. with increasing mol. size, with degree of dehydration, and with ease of pptn. Vegetable nontannins decrease astringence of vegetable tannins because they have a dispersing action and inhibit pptn. Acid plays a similar role with Cr tanning compds. The apparently simple mols. that have tanning properties (e. g., HCHO, quinone) are believed to polymerize during tanning. The fundamental reaction of tanning is a mutual dehydration of protein and tanning agent. Complex mols. form stable compds. with collagen, while their simple parent substances do not, because each mol. of the former is combined with many protein groups. Although OH groups nearly always are present in tanning compds., it is questionable whether this is a functional group responsible for all tanning action. H. B. Merrill

Penetration of tannin into leather. A. Deforge. *Halle aux cuirs* **1939**, 193–7; cf. preceding abstr.—Tannin mols. must penetrate between the micelles as well as between the fibrilles. Penetration decreases with increasing astringence, partly because the large mols. cannot penetrate the intermicellary spaces, and partly because they block the interfibrillary spaces (case-hardening). Acid swelling causes expansion of intermicellary spaces but contraction of interfibrillary spaces. Moderate plumping is desirable, but excessive plumping greatly retards penetration. The author questions whether Cr tanning compds. penetrate between the micelles, and suggests that one function of the hot drying of Cr leather may be to dehydrate the untanned interior of the fibrilles. H. B. Merrill

Chrome liquors. XI. The effect of excess sugar during reduction upon the basicity. Edwin R. Theis and Jerome Ganz. *J. Am. Leather Chem. Assoc.* **34**, 705–9(1939); cf. *C. A.* **33**, 9705⁷.—In liquors prepd. by adding H_2SO_4 to sugar-dichromate solns. contg. variable sugar, and boiling under reflux, the observed basicity was always lower than that calcd. from the dichromate–acid ratio, owing to formation of org. acids. The basicity decreased with increasing excess of sugar. The min. excess of sugar for complete reduction increased with increasing basicity. Oxalic acid in the finished liquor increased with sugar content up to about 30% excess sugar, and was thereafter const. **XII. Comparison of the chemical characteristics of basic chromium sulfate liquors made with and without reflux.** *Ibid.* **34**, 709–11(1939).—The lowering of the basicity caused by org. acids formed from incomplete oxidation of sugar was almost as great when reduction was done in an open vessel (simulating com. practice) as when done under reflux. Prolonged boiling raised the basicity slightly by partial expulsion of volatile acids. H. B. Merrill

Determination of chromic oxide in leather. I. Comparison of wet and dry oxidation methods. J. C. Mertz. *J. Am. Leather Chem. Assoc.* **35**, 36–44(1940).—Six com. Cr leathers were analyzed by: (I) the A. L. C. A. method (alk. fusion of ash, iodometric titration) (**a**) without and (**b**) with removal of Fe; (II) the Smith-Sullivan H_2SO_4-HNO_3-$HClO_4$ wet oxidation method (*C. A.* **29**, 6793⁸) with iodometric titration, (**a**) without and (**b**) with removal of Fe; (III) oxidation as in II and titration with $FeSO_4$ and Na diphenylamine sulfonate. **Ib** and **III** gave results that were in excellent agreement; **IIb** gave lower results; **Ia** and **IIa** gave results up to 0.2% higher than **Ib** and **IIb**, owing to the presence of Fe in com. Cr leathers. **III** is preferred. H. B. Merrill

A further study of the collagen-formaldehyde reaction. J. H. Highberger and I. S. Salcedo. *J. Am. Leather Chem. Assoc.* **35**, 11–24(1940); cf. *C. A.* **33**, 3199⁵.—To test the hypothesis that the increased HCHO fixation at pH values higher than 7 is due to combination with the basic group of arginine, hide powder was tanned in 1% HCHO solns. at pH values from 4 to 11 after having been partially freed from arginine by Sakaguchi's alk. hypochlorite method (*C. A.* **20**, 925). This treatment reduced the arginine content by about 43%. The wt. of HCHO fixed was lower for the dearginated material than for untreated collagen at all pH values above 4; the difference increased with increasing pH value; and at pH = 11 it was roughly equiv. to the amt. of arginine removed. The effect of concn. of HCHO was studied by tanning untreated collagen at pH values from 4 to 10 in solns. contg. 3 to 25% HCHO. Fixation increased with concn. at all pH values, and the pH-fixation curves were alike for all concns. Each curve had a flat portion near pH = 7, shifted slightly to the acid side for the higher concns. For tannage at pH = 7, the fixation-concn. curve was initially steep, and flattened out for higher concns. This is contrary to expectation if the enhanced fixation at higher concns. is due to formation of HCHO polymers, since these form most abundantly in the most concd. solns. It is thought that increased HCHO concn. causes more than one HCHO mol. to be fixed by one lysine NH_2 group—the apparent limit being 2. H. B. Merrill

Formaldehyde tannage in relation to the structure of collagen. J. H. Highberger and Fred O'Flaherty. *J. Intern. Soc. Leather Trades' Chem.* **23**, 549–56(1939); cf. preceding abstr.—A summary of the work of Highberger, *et al.* H. B. Merrill

Behavior of reticular tissue of animal skin. W. T. Roddy and Fred O'Flaherty. *J. Am. Leather Chem. Assoc.* **34**, 671–87(1939).—This tissue supposedly surrounds the collagen fiber bundles. Its staining reactions are almost identical with those of collagen. On the assumption that the connective tissue of the adipose tissue is similar in compn., a material was prepd. by extg. the lipides with petr. ether, and its properties were compared with collagen and elastin. This defatted adipose tissue was readily digested by pepsin, digested with difficulty by trypsin, lost N in the form of albumins, globulins and mucoids when digested with 10% NaCl soln., and possessed an acid-alkali swelling capacity slightly greater than that of elastin but much below that of collagen. When a skin is plumped in lime liquor, the reticular tissue probably is ruptured; this explains why over-plumping may result in loose leather, while moderate plumping is desirable in promoting tannage. H. B. Merrill

Foot and mouth disease. III. An analytical method for determining fluorides in [tannery] soak waters. E. E. Doherty and Walter Retzsch. *J. Am. Leather Chem.*

Assoc. **35**, 132-7(1940); cf. *C. A.* **33**, 5696⁹.—F is titrated with $Th(NO_3)_4$ with Zr-alizarin indicator (cf. Willard and Winter, *C. A.* **27**, 681) after distn. from H_2SO_4 into NaOH. As variation in NaCl affects the result, the filtered soak water is made to 5% NaCl. A correction chart is given. Soaks contg. more than 125 p. p. m. F are dild. before distn. Analysis of used soaks contg. $NaHF_2$ show that about half the initial F remains in the liquor. H. B. Merrill

Sampling butt bends. Committee report. L. M. Whitmore, *et al. J. Am. Leather Chem. Assoc.* **34**, 699-705(1939).—Comparative analytical results are given for samples cut from 3 positions: (I) composite samples from 5 positions (present provisional method), (II) one position at the shoulder end near the backbone line, and (III) a strip extending completely across the shoulder end. Results from II are not widely different from those obtained from I, while III is much higher in oil content. II is recommended for economy. H. B. Merrill

Effect of finish on the deterioration of vegetable-tanned upholstery leather. H. B. Walker. *J. Am. Leather Chem. Assoc.* **34**, 687-98(1939).—Leather samples, variously finished with nitrocellulose, were exposed repeatedly to (1) SO_2, (2) ozone, (3) H_2O vapor. Deterioration was measured by detg. the decrease in bursting strength after 1 and 3 months. The standard leather with grain completely sealed by the finish showed negligible deterioration, and deterioration increased with increasing openness of grain, to a max. of 70% loss in initial strength for unfinished leather. pH values of aq. leather exts. after 3 mo. exposure were all low (2.0 to 2.5). It is suggested that all or part of the absorbed acid may be retained by the nitrocellulose film. H. B. Merrill

Air-burn control in drying heavy leather. J. W. Moore and Frank C. Vilbrandt *Bull. Virginia Polytech. Inst., Eng. Expt. Sta. Series Bull.* No. **41**, 3-26(1939).—Small pieces of sole leather were dried at low temp. and high humidity after washing for various periods. "Air burn" (darkening) was produced in pieces inadequately washed even when they were dried at 32°F. and 90% relative humidity, and regardless of rate of air flow. After the surface H_2O was evapd., rate of drying increased owing to exposure of fiber surfaces, but this was partially offset by deposition of tanning material on and between the fibers. H. B. Merrill

Influence of natural nontannin on the deterioration of chestnut and quebracho leathers by sulfuric acid. R. C. Bowker and R. B. Hobbs. *J. Am. Leather Chem. Assoc.* **35**, 4-11(1940); cf. *C. A.* **27**, 2334.—Addn. of excess nontannin has been found to give considerable protection against deterioration by acid gases absorbed from the atm. (Innes, *C. A.* **28**, 1215⁶; Frey and Beebe, *C. A.* **29**, 7112³). This work deals with the effect of nontannin in preventing deterioration by acid present initially. Nontannin (and several times as much tannin) was added to quebracho or chestnut leathers by soaking each of them in solns. of quebracho and chestnut exts. The treatment with chestnut about doubled the sol. nontannin content, while the quebracho treatment added very little nontannin. These leathers, and controls not loaded with nontannin, were treated with varying wts. of H_2SO_4, so that the aq. exts. of the leathers had pH values from 5.2 to 2.3. After aging 12 and 24 months, all leathers whose aq. exts. had pH values below 3 showed marked loss in tensile strength, indicating that addn. of a small amt. of these particular nontannins had no effect on the pH value at which rapid deterioration occurs. H. B. Merrill

Quality of leather. IV. Influence of method of tanning on composition, strength and resistance to wear of the different layers of leather. Fritz Stather and Hans Herfeld. *Collegium* **1939**, 609-30; cf. *C. A.* **33**, 3627⁵.—Ten vegetable-tanned leathers, 5 tanned by the old, pit method (I) and 5 by the modern method (II) were split into 3 layers (grain, middle, flesh) of approx. equal thickness and each layer was analyzed. For all leathers ash, sol. org. matter, degree of tannage yield and pH were highest in the outer layers. The ranges in percentage of ash in the grain, middle and flesh layers of I were 0.6-1.2, 0.2-0.6 and 0.5-0.9, resp., and for II 1.6-3.6, 0.9-2.4 and 1.4-2.8, resp. Ranges in percentage of sol. matter in these layers were for I 7.0-9.5, 6.0-7.2 and 6.5-7.9, and for II 14.6-27.6, 10.9-19.5 and 13.8-24.9. The pH range for both I and II was 3.9-4.4 for the middle and 4.1-4.6 for the grain and flesh layers. To det. why the middle layer was tanned less than the outer layers comparable pieces were tanned in the lab. by 7 methods, one set before and another after splitting the skin into 3 layers. The tannages were dil. vegetable liquor at pH 5, vegetable liquors of increasing concn. at pH 5 and pH 3.5, a dil. Cr liquor and a concd. Cr liquor each made basic near the end of the tannage and a concd. Cr liquor made basic before the tannage started. One piece of skin was dehydrated with alc., dried and tested in the untanned condition. Fixation of tannin was greatest from concd. liquors or those of high basicity or low pH. The outer layers contained more fixed tannin or Cr than the middle layer if the leather was split after tannage. The difference was greater the more astringent the tannin, whether this astringency increase was caused by increase in concn., basicity or acidity. The difference in fixed tannin in the 3 layers of leather split before tanning was negligible. The protein of the middle layer therefore does not have a lower ability to fix tannin but is tanned to a lower degree because the outer layers absorb the more astringent tannins, and the tannin reaching the interior is of lowered astringency. Sol. matter in the outer layers is somewhat higher than that in the middle layer even when the skin was split before tanning. This is not caused by astringency of the tannin, by blood vessels or hair holes in the skin, but seems to be connected with the fine structure of the skin. A similar effect was found with salt brine (*C. A.* **29**, 7110¹). Tensile strength was lowered by tanning and the greater the intensity of tanning the lower the strength. The middle layer was therefore stronger than the outer layers. For good strength a leather should have a uniform tannage of moderate intensity. Cr leather was stronger and wore better than vegetable leather. The wear resistance of tanned skin was better than that of untanned, alc.-dehydrated skin. But above a certain intensity of tanning the wear resistance was lowered so that tannage to satn. is not desirable. I. D. Clarke

The waterproofness of vegetable-tanned sole leather. R. S. Edwards. *Wetting and Detergency Symposium, Feb. 19-20*, **1937**, *Brit. Sect. Intern. Soc Leather Trades' Chem.* 67-75. **The wetting of skin and leather.** R. H. Marriott. *Ibid.* 85-95.- Review. M. M. Piskur

Food for leather belts. J. A. Webb. *Southern Power and Ind.* **58**, No. 2, 76-8(1940).—After a belt is placed in service the oils present in the belt tend to oxidize; this increases the pulling power of the belt. In future, belts will probably be impregnated with preoxidized oils to decrease the breaking-in period. However, this pulling power is decreased by loss of oils from the belt, amounting to about 30% the 1st year, 15% the 2nd year and somewhat lesser amts. in later years. The belt should be lubricated with beef tallow or neatsfoot oil to preserve its pulling power and prevent dry rot. R. W. Ryan

Dyes and tans in species of statice (Mell) **25**. Derivs. of phenol obtained from cashew-nutshell oil [for odorizing leathers] (U. S. pat. 2,181,119) **10**. Waterproofing fibrous materials such as leather (U. S. pat. 2,182,045) **25**. Aluminum silicate compns. for use with glue (U. S. pat. 2,182,086) **18**. Assistants for use in leather and textile treatments (U. S. pat. 2,181,476) **13**.

Trisazo dyes. Emil Senn (to J. R. Geigy A.-G.). U. S. 2,183,087, Dec 12. See Brit. 500,415 (*C. A.* **33**, 6061⁵).

Glue. Walter M. Urbain and Lloyd B. Jensen (to Industrial Patents Corp.). U. S. 2,182,186, Dec. 5. See Can. 384,588 (*C. A.* **34**, 1510⁸).

Glue. Charles N. Cone (to M and M Wood Working Co.). U. S. 2,182,425, Dec. 5. A water-resistant glue for gluing wood is formed of animal glue, about 4-8 times as much water as glue, and Na silicate (suitably about 50%

as much as glue) in sufficient proportion to maintain adhesive properties of the glue when viscous at room temp. suitable for gluing wood veneers with formation of a water-resistant bond.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

T-50 test as a control for inner tubes. Wm. B. Dunlap, Jr. *India Rubber World* **101**, No. 2, 47–8(1939).—The applicability of the T-50 test to control of factory production of inner tubes was investigated. Under otherwise the same conditions, the T-50 values of factory cures were consistently lower than those of lab. cures, but although, according to the T-50 test, factory-processed mixts. vulcanized more rapidly than the same mixts. not processed but lab. cured, combined-S detns. showed equal rates of vulcanization. Lack of uniformity of conditions in factory curing results in varying T-50 values in different sections of an inner tube. The direction of elongation in the T-50 test with respect to grain in the rubber has practically no influence on T-50 values. Judged both by the T-50 test and by combined-S detns., remilling of a factory mixt. retards its rate of vulcanization, and with alternating short periods of remilling and rest, this retardation increases rapidly to an approx. const. T-50 value. C. C. Davis [1]

The natural aging of rubber-sulfur compounds. I. Changes during the first four months. T. R. Dawson and J. R. Scott. *J. Rubber Research* **8**, 87–103, 104–23(1939). A rubber–S (95.5) mixt. was vulcanized in a press at 153° to coeffs. of vulcanization of 1.88, 3.90, 4.79 and 4.99, resp., the products were stored in darkness for 4 months, and periodically the changes in tensile strength, elongation at fixed loads, resilient energy, permanent set, hardness, scleroscope resilience, wt., vol., d., swelling in C_6H_6, acetone ext. and vulcanization coeff. were measured. Special attention was paid to the unstable condition during the first 2 days after vulcanization and the progress of the subsequent "settling down" phenomena before deterioration became appreciable. The results, which are recorded in graphical form, give evidence of various significant changes, including slowly increasing tensile strengths throughout the 4 months; decreasingly rapid declines in elongation at rupture; decreasingly rapid increases in stretch modulus; initially rapid increases, then gradual decreases in resilient energy at const. load; initially rapid, then slow increases in resilient energy at const. elongaton; erratic values of permanent set after rupture; initially rapid decreases, then insignificant changes in permanent set after 400% elongation; initially rapid increases in hardness (plastometer); initially rapid decreases in scleroscope resilience followed by uncertain changes; initially rapid increases, then in appreciable changes in d.; slow decreases in max. swelling; gradual increases in sp. swelling increment; initial decreases and subsequent increases in standard swelling time; and insignificant changes in acetone-sol. substances and in coeff. of vulcanization. These results are discussed critically, and an attempt is made to correlate, with the aid of graphs, the various properties mentioned above. Among the significant deductions are that: (1) permanent set at const. elongation, plastometer hardness, scleroscope resilience and max. swelling and elongation at const. load were linear functions of one another; (2) permanent set at rupture was a linear function of the tensile strength and permanent set at const. elongation; (3) standard swelling time and specific swelling increment were linear functions of max. swelling; (4) the swelling properties bore no simple relation to the vulcanization coeff.; (5) changes in max. swelling by aging did not depend merely on changes in vol. and in resin content; (6) rigidity and elongation at rupture were related by a simple inverse curvilinear function; (7) resilient energy was a linear function of stress modulus and tensile strength; (8) the energy absorbed in stressing to a certain degree was independent of the state of cure or age (cf. Gurney and Tavener, *C. A.* **16**, 1337). Probably many of these linear relations would have no longer been true after prolonged aging. Many, if not all, the relations may represent practically rectilinear portions of aging curves, and probably these linear relations would have no longer been true after more extended aging. C. C. Davis [2]

Tube mold for making Schopper tensile test rings. E. B. Johnson. *J. Rubber Research* **8**, 131–4(1939). C. C. Davis

Evaluation of carbon black by rate of cure and extrusion. C. R. Johnson. *India Rubber World* **101**, No. 2, 39–40 (1939).—A statistical comparison of various types of C black by the percentages of volatile matter, adsorption of diphenylguanidine, pH values, plasticities (Firestone-Dillon method) and T-50 test shows that, in general, blacks with high percentages of volatile matter are characterized by high diphenylguanidine adsorption values, low pH values, high temps. in the T-50 test, difficult processing and retarding effects on vulcanization. The plasticities did not show such well-defined relations, but the blacks which gave the most plastic rubber-black mixts. showed low diphenylguanidine adsorption values. C. C. D. [3]

Carbon black estimation in vulcanized rubber. H. A. Curran. *India-Rubber J.* **98**, 747–8(1939).—In detg. C black in rubber or rubber mixts., kieselguhr on the asbestos in the Gooch crucible is unnecessary, and C black is retained much better if an underbed of finely chopped asbestos and then alternating beds of finely carded and finely chopped asbestos are built up to a thickness of $^{3}/_{16}$ in. The asbestos should first be digested for 4 hrs. in boiling concd. HCl (frequently renewed). Also, washing successively with CCl_4 and water after the concd. HNO_3 treatment is recommended. **Comments.** Charles Avons. *Ibid.* **99**, 41(1940).—A simpler technique (without kieselguhr) is merely to keep the asbestos pad and its contents always covered with a small vol. of the last wash liquor, disconnecting the suction if necessary (cf. Oldham and Harrison, *C. A.* **31**, 5617[1]). C. C. Davis [4]

Effect of vulcanization on rubber structure. Warren F. Busse. *Ind. Eng. Chem.* **31**, 1391–7(1939).—A crit. review and discussion of present knowledge, with particular attention to the structure of crude rubber, the limitations of the classic theory of vulcanization, vulcanization in soln. and the effects of compounding ingredients on the vulcanization of rubber in the solid state. Stress is laid on the fact that, since rubber mols. are extremely large and flexible, chem. reactions of too small a magnitude even to be identified can have an enormous effect on its phys. properties. Products are formed according to the laws of probability, but if they cannot be identified or even detected, it should be possible, by proper interpretation of accumulated phys. and chem. data, and more sensitive phys. and chem. tests, to obtain definite information on the various structures formed by vulcanization. A systematic study of the part played by accelerators should be particularly valuable. C. C. Davis [5]

Physical changes induced by vulcanization. W. W. Vogt. *Ind. Eng. Chem.* **31**, 1389–90(1939).—A review and discussion of present knowledge. C. C. Davis [6]

Relations between vulcanization and reënforcement. C. R. Park. *Ind. Eng. Chem.* **31**, 1402–6(1939).—Four questions are considered: (1) the relative effects of vulcanization and of powder reënforcement on the phys. properties of rubber; (2) whether rubber hydrocarbon is permanently modified by powders and if so, whether the change is like that by vulcanization; (3) whether small proportions of ZnO and larger proportions of certain other powders on the stress-strain curve of vulcanized rubber have similar effects, and (4) the effects of reënforcing powders on the rate of vulcanization. These subjects are discussed critically in the light of various investigations (45 references), in some cases with the inclusion of new data in support of the arguments. In summary, it is [7]

unlikely that the phys. effects of vulcanization are the result of reënforcement by rubber sulfide particles in a state of great fineness and high dispersion. There is evidence that changes in rubber brought about by finely divided powders may be attributable to oxidation of rubber hydrocarbon. The products are analogous, both physically and chemically, to rubber S compds. The peculiar effect of ZnO on rubber-S mixts. indicates that it plays an active part in vulcanization and that it has a reënforcing effect which is independent of org. accelerators and which is disproportionately great for its particle size. Differences in the effects of powders on rate of vulcanization can be explained by differences in the nature of their surfaces, which governs the adsorptive power, and results in preferential adsorption of certain components of the system.
C. C. Davis

Qual. variations of rubber in roots of kok-sagyz at second year (Mashtakov) **11D**. Measurement of cross-section of rubber on insulated wires (Richter) **13**. Application of chlorinated rubber-tar products to jute fabrics (Pratt, Handley) **25**. Polymerization and production of new synthetics [in rubber industry] (Harold) **13**. Al silicate compns. for use with rubber (U. S. pat. 2,182,086) **18**. Microporous diaphragms [contg. rubber] for storage-battery separators (U. S. pat. 2,181,299) **4**. Rubberizing regenerated-cellulose rayon (U. S. pat. 2,181,538) **25**. Microporous battery separators of hard rubber (U. S. pat. 2,181,891) **4**. Sausage casing [rubber-coated] (U. S. pat. 2,181,886) **12**.

Fischer, Karl: Blutgummi; Roman eines Rohstoffes. Berlin: Kommodore-Verlag. 176 pp.

Rubber compositions suitable for use as dielectrics, for films, etc. Anderson W. Ralston and William M. Selby (to Armour and Co.). U. S. 2,182,180, Dec. 5. Unvulcanized rubber is dissolved in a solvent such as $C_2H_2Cl_4$ and mixed with stearic acid or other fatty acid contg. a least 6 C atoms, $AlCl_3$ is added, the reaction mixt. is heated to about 140° for 6 hrs. and after the reaction is complete is hydrolyzed, as by heating in the presence of HCl to liberate an Al-free product.

Rubber mixtures suitable for various purposes. Georg Goll and Ernst Helft (to Deutsche Hydrierwerke A.-G.). U. S. 2,181,426, Nov. 28. Raw rubber is used with an emulsion of water and a higher mol. fatty alc. contg. 12 to 18 C atoms in the mol., such as stearic or oleyl alc.

Treating rubber, etc. United States Rubber Products, Inc. Brit. 508,129, June 27, 1939. This corresponds to Fr. 837,635 (*C. A.* **33**, 6654[1]), R, R^1 and R^2 representing C atoms of nonaryl hydrocarbon groups.

Chlorinating rubber. Wm. H. Stevenson (to Hercules Powder Co.). U. S. 2,182,456, Dec. 5. A method for the manuf. of a chlorinated deriv. of rubber involves treating rubber in soln. in CCl_4 with Cl at a temp. of about 40–60° until the Cl content is about 52–63%, then treating the partially chlorinated material for about 2–5 hrs. at a temp. of about 30–40° with a mixt. of Cl and an O-contg. gas such as air and thereafter continuing the addn. of such gas mixt. until a chlorinated deriv. of rubber is obtained having a viscosity greater than about 20 centipoises and contg. at least 64% Cl.

Chlorinated rubber. Walter E. Gloor (to Hercules Powder Co.). U. S. 2,182,473, Dec. 5. A method for increasing the apparent d. of chlorinated rubber comprises crushing, by the application of pressure, wet, fluffy, porous particles of chlorinated rubber of low apparent d., while wet with not less than about 45% by wt. thereof of water, producing thereby small, thin, chip-like, discrete flakes of chlorinated rubber having an apparent d. of at least 15 lb. per cu. ft. when dry. Cf. *C. A.* **33**, 8445[7].

Apparatus for continuously extruding materials such as chlorinated rubber that under treatment at elevated temperature undergo expansion on release of the pressure. R. P. R. Association, Cyril A. Redfarn and Philip Schidrowitz. Brit. 507,926, June 23, 1939.

Preserving rubber. Wm. Baird and Maldwyn Jones (to Imperial Chemical Industries Ltd.). U. S. 2,181,719, Nov. 28. As an inhibitor of oxidation, there is incorporated with rubber (suitably about 1%) of a 2,6-xylenol (OH = 1) substituted in the 5-position by a methyl group having one H replaced by a piperidino, morpholino or dialkylamino radical (each alkyl group contg. 1–4 C atoms).

Rubber-coating gloves. Edward E. Montgomery (to Edmont Mfg. Co.). U. S. 2,181,247, Nov. 28. A glove of canvas or other material is submerged in liquid latex, and while the latex surface is wet or tacky dry ground rubber is sprayed onto it by a compressed air spray gun.

Laminated rubber shoe soles and heels suitable for repair purposes. Albert L. Murray. U. S. 2,181,379, Nov. 28. A mfg. process involves forming a layer of relatively thin raw rubber derived from rubber cement substantially free from surface skin and evapg. the liquid therefrom, forming a layer of relatively unweakened, relatively tough rubber free from vulcanizing agents and having skin-forming tendencies and derived from rubber latex and evapg. the liquid therefrom, the rubber latex comprising coned. milk of latex in an amt. sufficient to prevent migration of vulcanization therethrough, forming a layer of vulcanizable tread stock, the unweakened latex rubber layer being between the other cement rubber and tread stock layers, and then permanently consolidating the layers by heat and pressure, the heat vulcanizing the tread layer and vulcanizing the intermediate layer thereto, the latter preventing migration of vulcanization to the thin, cement-derived raw rubber layer.

Fabrics comprising rubber threads. Thomas L. Shepherd. U. S. 2,182,996, Dec. 12. A fabric is made by a method involving coating elastic rubber thread with a sol. material such as gelatin and allowing or causing it to dry, whereby the thread can no longer be substantially stretched, then leading the thread into a machine for mfg. the fabric, and subsequently removing the coating material, as by washing, to leave the threads in stretchable condition.

Rubber mill with adjustable spaced rolls. Edwin J. Mellvried and Norman H. Nye (to Vaughn Machinery Co.). U. S. 2,182,900, Dec. 12. Various structural and mech. details.

Rubber covered platens for typewriters, etc. Alfred E. Vickery (to Remington Rand, Inc.). U. S. 2,182,141, Dec. 5. A platen is provided with a covering of the usual vulcanized natural rubber compn. having a degree of hardness and resiliency to afford proper typing by the force of the types thereagainst, and a protective coating applied over the natural rubber compn. covering in a sufficiently thin layer to provide a platen having substantially the hardness and resiliency of the underlying compn. covering, the protective coating comprising a rubber-like material having the properties of resisting oxidation and deterioration by rubber solvents, such as a polymerized chloroprene compn.

Continuous vulcanizing apparatus, suitable for strip material. Thomas M. Knowland (to Boston Woven Hose & Rubber Co.). U. S. 2,182,317, Dec. 5. Various structural, mech. and operative details.

Continuous vulcanizing apparatus suitable for belting or matting. John M. Bierer (to Boston Woven Hose & Rubber Co.). U. S. 2,182,168, Dec. 5. Various details of an app. having a heated vulcanizing drum and assocd. pressure band, etc.

Apparatus for continuous vulcanizing of belting, etc. Walter J. Baker and Cecil J. H. Perry (to Boston Woven Hose & Rubber Co.). U. S. 2,181,859, Dec. 5. Various structural, mech. and operative details.

Vulcanizing press suitable for floor mats, etc. Edmund M. Winegar (to Ohio Rubber Co.). U. S. 2,182,833, Dec. 12. Various structural, mech. and operative details.

Vulcanizing press suitable for rubber tires and tubes, etc. Cato Iverson (to National Rubber Machinery Co.). U. S. 2,181,273, Nov. 28. Various structural, mech. and operative details.

CHEMICAL ABSTRACTS

Vol. 34 APRIL 20, 1940 No. 8

1—APPARATUS, PLANT EQUIPMENT AND UNIT OPERATIONS

W. L. BADGER

Containers for the transport of brittle and solid chemicals. N. F. Ermakov. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 8–11(1939). H. M. Leicester

A pump for moving sulfuric acid at 130–150°. P. A. Vasil'ev. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 48 (1939).—Pb rings replace asbestos as packing. H. M. Leicester

Addition to the article "Use of Hempel's four-bulb gas pipet." Leopold Wolf. *J. prakt. Chem.* **154**, 284 (1940); cf. *C. A.* **33**, 9050⁸.—The pipet construction described by W. has been previously reported by Fleissner (*C. A.* **2**, 2749). C. J. West

A new stirring machine. Josef Bitskei. *Z. anal. Chem.* **118**, 170–1(1939).—A stirrer is described which is suitable for use during titrations. The app. is provided with a 'stirring plate' which is beneath the beaker contg. the soln. to be titrated. The plate is set in motion by means of 2 eccentrics, of the same dimensions, connected in such a way they both work uniformly and in the same direction. All parts of the table and all parts of the beaker are kept in circular motion so that the soln. is given a steady swirling effect without fear of loss by spattering. W. T. H.

Sampling apparatus. P. I. Bozhenov. *Tsement* **6**, No. 4–5, 48–50(1939).—The material is poured in a funnel, from which it falls over a dividing cone into a dividing funnel partitioned into 4 equal sections; the material from each pair of opposite sections is combined and forms the "mean sample." The device can be used for any finely crushed materials. E. E. Stefanowsky

Bottom-sampling apparatus. Jack L. Hough. *Recent Marine Sediments: a symposium, Am. Assoc. Petroleum Geol.* **1939**, 631–64.—A description of app. for sampling of deposited sedimentary material, for collecting material in suspension in water and for studying ripple-marks. Fifty-two references. George Ayers

An apparatus for continuous filtration. Walter Frost. *Chem.-Ztg.* **64**, 60(1940).—A practical app. that eliminates the tedium of hand filtration consists of an Erlenmeyer flask fitted at the bottom with a roomy discharge buret stop-cock, which, when open acts like a siphon. The liquid to be filtered is put in this flask, which is sealed with a rubber stopper through which extends a glass tube that reaches the bottom of the flask. The position of this tube dets. the level at which the liquid is maintained in the filtering funnel. The operation is entirely automatic. Since the filtering funnel is always kept filled to the rim, the optimum filtering speed is insured. A. W. K.

Fractional distillation apparatus. E. Wertyporoch. *Acta Polon. Pharm.* **2**, 299–301(1938); *Chimie & industrie* **42**, 272.—The app. is an improvement on the Golodetz double-rectifier (cf. *C. A.* **7**, 1). Its features consist in the distn. tube which has an inner bulb tube terminating at the bottom in a capillary tube through which the undistd. portions reflux. The fraction to be sepd. is condensed in a condenser at the side of the app. The double rectifier is insulated by means of cotton; it is surrounded with a heating jacket for high-temp. distn. of substances which crystallize easily at medium temps. A. P.-C.

A new apparatus for microdeterminations of molecular weights according to Pregl-Beckmann. Karl Bürger. *Chem. Fabrik* **1940**, 54–5.—The app. can be used only in connection with the Hoeppler ultrathermostat. It is described in detail with 1 cut; exact operating directions are given, and results compared with calcd. mol. wts. J. H. Moore

Sealable absorption microtube. Arthur N. Prater. *Ind. Eng. Chem., Anal. Ed.* **12**, 184(1940).—This modified Friedrich tube (*C. A.* **30**, 2⁹) has larger capacity, weighs less than 15 g. when full and contains sufficient absorbent for 25 analyses. The gain in wt. on standing is only about 1/4 that of the regular Pregl tube. The tube is available commercially. T. H. Dunkelberger

An electrostatic ultramicroscope of high resolution. H. Mahl. *Z. tech. Physik* **20**, 316–17(1939).—A purely electrostatic app. using two electric lenses is described. The resolution is under 15 mμ. Photomicrographs of MgO (16,000 x), of a film of vaporized Ag (90,000 x) and of three bacilli (9000 x) are given. J. B. Austin

A new simple ultramicroscope and its use in bacteriology. E. Brüche and E. Haagen. *Naturwissenschaften* **27**, 809–11(1939).—A review of work done with the Mahl electron microscope using an elec. (instead of magnetic) field as lens (*Ibid.* 417; and preceding abstract). A no. of photomicrographs of bacteria with 7500–9700 magnification are reproduced. Inner structures of the bacteria and their flagellas are plainly visible. B. J. C. v. d. H.

An electron shadow-microscope. I. Geometric and optical studies. H. Boersch. *Z. tech. Physik* **20**, 347–50(1939); cf. *C. A.* **33**, 8102⁹.—The resolution is better than 10^{-6} cm. and approaches that of other ultramicroscopes. Shadow pictures are given for a wire, kieselguhr, diatoms, MgO and an infusion of hay. J. B. Austin

A new method of gas analysis. W. J. Gooderham. *J. Soc. Chem. Ind.* **59**, 1–8(1940); cf. *C. A.* **33**, 1472¹.—The mixt. of gases to be analyzed, adjusted to a const. pressure, is allowed to flow though a control capillary and the app. out to the air without any appreciable change in pressure. The individual constituents of the gas are removed by suitable reagents in special scrubbers and (or) furnaces. The decrease or increase in vol. causes a change in rate of flow of the gas. This rate is measured by timing the travel of a soap, or soaplike film, pushed by the gas through a calibrated vessel. As there is no Hg in the app. activated nitrating mixt. can be used for detg. unsatd. hydrocarbons. A new form of gas holder made of corrugated metal rings and a special type of governor is described. Joseph H. Wells

Oxygen and carbon dioxide analyser and an oxygen flowmeter for use in aircraft compartments at high altitudes. J. W. Heim. *J. Aviation Med.* **9**, 144–9(1938).—A Wheatstone-bridge method for gas analysis giving continuous readings is described. B. C. P. A.

Compact gas saturator. Aaron E. Markham. *Ind. Eng. Chem., Anal. Ed.* **12**, 112(1940).—A gas-washing bottle is described. The principal feature is a spiral tube using the airlift system of stirring. W. F. Bruce

An absorption bulb for detecting various gases. Wilbur Simon and J. H. Reedy. *Trans. Illinois State Acad. Sci.* **32**, No. 2, 128–9(1939).—A trap, patterned after the Liebig bulb, is used to absorb such gases as CO_2, SO_2, H_2S, I_2, Br_2, H_3BO_3 and AsH_3, given off in microqual. tests. High sensitivities are reported in most cases. J. H. Reedy

Dialysis apparatus. Saburo Kamei, Saiti Nisida and Yatuka Ikeda. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 431–4(1939).—Two- and three-compartment cells with parchment membranes were used to dialyze NaOH

recovered from sodium cellulose manuf. Hydrostatic head was found to be the only pressure of importance acting upon the membranes. H. G. Bowlus

An apparatus for the supply of liquid into a reaction chamber with constant flow, and an apparatus for the catalytic dehydration of alcohol. Masaharu Katuno. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 424–6 (1939).—A const. discharge from a capillary tip at the bottom of a tube is obtained by using a separatory funnel to maintain a const. head in the tube. Pressure-equalizing lines are provided. This app. is used to feed alc. to the usual type of elevated-temp. catalytic equipment. H. G. Bowlus

Continuous extraction of aqueous solutions by acetone-petroleum ether. M. Wayman and G. F. Wright. *Ind. Eng. Chem., Anal. Ed.* **12**, 91(1940).—An extractor is described in detail for extg. satd. NaCl solns. with Me_2CO—60–90° petroleum ether (3:1). The latter prevents accumulation of H_2O in the boiler. W. F. Bruce

Distribution of argon in oxygen-argon separating apparatus. I. P. Ishkin and P. Z. Burbo. *J. Tech. Phys.* (U. S. S. R.) **9**, 1677–82(1939).—The concn. of A at various stages of rectification was detd. by absorption of O_2 by Cu and measurement of the sp. gr. of the remaining N_2-A mixt. The sepn. of A from O_2 in rectifiers gives best results when the mixt. contains 90% of O_2 in the liquid and 88% of O_2 in the gas phase. J. J. Bikerman

Sedimentation and flocculation. M. B. Donald. *Chemistry & Industry* **1940**, 105–9; *Trans. Inst. Chem. Engrs.* (London), Advance copy, Feb. 13, 1940, 7 pp.—Review with 32 references. Also in *Engineering* **149**, 248–9(1940). E. H.

On the collection and separation of dust. Zyuniti Isobe. *J. Japan. Ceram. Assoc.* **47**, 17–19, 196–200 (1939).—The motion of particles in falling through horizontal steady flow is mathematically treated. Efficiency of dust chamber or separator depends mainly on the height and length of the chamber and on the velocity of flow. A dust chamber must be built as low and long as possible while a separator must be built adequately high and short. S. Kondo

The practice of separating minerals in accordance with their specific gravities by centrifuging in heavy liquids. V. N. Dominikovskiĭ. *Razvedka Nedr* **8**, No. 4–5, 44–9 (1938); *Chem. Zentr.* **1938, II**, 3428.—Heavy liquids (e. g. "Tule," d. 2.8–3.1) as well as such mixts. as $CHBr_3$-alc., $CHBr_3$-toluene, $CHBr_3$-oil and MeI-toluene are used in the centrifuging of minerals. The grain size of the minerals is a decisive factor, as failure is unavoidable if the grain size is not reasonably uniform. The liquid mixts. named above can be sepd. by freezing out. M. G. M.

Granular materials. Particle-size distribution. Walter H. Dumke. *Mines Mag.* (Colo. School of Mines) **30**, 61–4, 74(1940).—An address. Leopold Scheflan

Disperse hysteretic differential wetting and flotation of quartzite of the hematite variety from Krivoi Rog. I. R. Klyachko and V. I. Trushlevich. *Gornyĭ Zhur.* **114**, No. 7, 46–50(1938); *Chem. Zentr.* **1938, II**, 3445–6; cf. *C. A.* **31**, 3338[5].—The mineral surface often becomes hydrophilic as a result of the adsorption of the flotation-reagents, in case their total concn. does not exceed 0.1–0.5 g./l. With the Krivoi Rog hematite as an example it was demonstrated that a good sepn. by flotation can be obtained with the use of a combination of reagents such that the wettability of the surface of the ore concentrate and tailings is increased. Sepn. by flotation is conditioned by the differential wettability. M. G. Moore

Apparatus for packing poisonous powders. V. N. Serov. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 46–7(1939). H. M. Leicester

An improved iodine apparatus. F. X. Gassner. *Ind. Eng. Chem., Anal. Ed.* **12**, 120(1940).—The metal torch described by v. Kolnitz and Remington (*C. A.* **27**, 681–2) is modified by shortening it, replacing the 4 O connections by a single inlet tube, and constructing it throughout of stainless steel. A simple trap is attached to eliminate the danger of explosion due to clogging by cinders of the constricted tip in the first wash bottle. The upper part of the torch is best covered by a 1-l. widemouth extn. flask with vial-type neck. Discoloration of this part of the torch is remedied by immersing it for 5 min. in a soln. contg. concd. HNO_3 (25%), HF (3%) and H_2O (72%) at 70°. T. H. Dunkelberger

Precision cryostat for the range −35° to +25°. Edwin E. Roper. *Ind. Eng. Chem., Anal. Ed.* **12**, 113–17 (1940).—A 7-l. cryostat with a mean bath temp. variation of ±0.0012° at −28.11° is described in detail. A household refrigerator unit operated continuously and a heating coil, both connected to an elec. control circuit, are described, and the operation is very fully given. W. F. Bruce

A simple quartz-fiber manometer of high accuracy. G. Wetterer. *Z. tech. Physik* **20**, 281–3(1939).—The damping of vibrations of a small disk attached to two thin quartz fibers gives a sensitive indication of the pressure over the range 10^{-1} to 10^{-5} tor. J. B. Austin

The luximeter. W. L. Carson. *Gen. Elec. Rev.* **43**, 91–2(1940).—This is a photoelectric instrument for measuring light transmission through a liquid; it consists of a lamp maintained at const. light intensity, a test-tube holder and light meter, all mounted in a small case. Light from the lamp passes through the liquid (in the test tube) to be measured, then to the photoelec. cell which actuates a sensitive indicating instrument. A rheostat in the lamp circuit controls the amt. of light required for a given test. Among the applications cited is the detn. of the degree of pasteurization of *milk*. The blue color intensity of the sample of milk is proportional to the amt. of phosphatase still present. The lighter the blue the more complete the pasteurization. The luximeter will measure turbidity quite well over the range 100 to 3500 p. p. m. on the silica scale. C. G. F.

Calculation of the loss of product in a vacuum evaporation system with a water barometer condenser. D. E. Zil'berman and E. Ya. Margulis. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 36–7(1939). H. M. Leicester

Evaporative index. Geo. S. Gardner. *Ind. Eng. Chem.* **32**, 226–31(1940).—A simplified approx. form of the Maxwell-Stefan equation is given for evapn. from a liquid surface: $E = (KD_1Mp_{a1})$, where E is evapn. rate, g./hr./sq. cm., D_1 is diffusivity, sq. cm./sec., M is mol. wt., p_{a1} is vapor pressure, mm. Hg. $K = \alpha/RTPx$, where P is total pressure, x is equiv. film thickness, and α is a proportionality const. E was detd. under const. conditions, with artificial convection, at 50°, for 18 org. liquids boiling from 62° to 193°, and plotted against the index (D_1Mp_{a1}). E, varying from 0.0143 to 1.197, is closely given empirically by $0.00258\ (D_1MP_{a1})^{0.87}$. Doolittle's values, using natural convection (*C. A.* **30**, 307[2]), are similarly analyzed, and show direct proportionality, with fair agreement. *Vapor pressures* from room temp. to the b. p. were detd. on all liquids. Cox curves (*C. A.* **17**, 2359) are given for those for which satisfactory values do not exist in the literature. From these charts, the vapor pressures in mm. Hg at 20° and the normal b. p. are: *isooctane*, 36, 100°; *butyl acetate*, 9.0, 126°; *isodecane*, 28, 160°; *diacetone alc.*, 1.05, 170°; *diisobutylene*, 35, 101°; *diisoamylene*, 26, 159°; *ethylene glycol monoethyl ether*, 39, 130°; *amyl acetate*, 29, 147°. Thirteen references. R. W. H.

Apparatus for drying small quantities of heat-sensitive solids. W. G. Whittleston. *New Zealand J. Sci. Tech.* **21B**, 162–3(1939).—A moist solid on a Büchner funnel was dried *in vacuo* by passing a stream of air through heated H_2SO_4 and thence by an inverted funnel to the Büchner. At 25° the solid was dried 3 to 4 times as rapidly as in a vacuum desiccator at room temp. The rate of air flow was 0.25 to 0.5 l. per min. The large tube connecting the acid and funnel was insulated and provided with a thermometer. W. F. Bruce

Temperature-measuring instruments. W. Bowen. *J. Inst. Fuel* **12**, 75–81S(1939).—Modern developments in resistance, thermoelec., radiation, and optical pyrometers are reviewed, special reference being made to the combined color-brightness pyrometer. A comprehensive bibliography is included. B. C. P. A.

A precision multiple-point thermometer outfit. G. M.

Dreosti and P. Wissing. *Union S. Africa, Dept. Agr. Forestry, Rept. Low-Temp. Research Lab.* **1937–38**, 176–202(1939).—A 240-point outfit, having extreme reliability, robustness and rapidity in use, was developed for precision work in cold-storage spaces. The thermocouple heads are only 0.25 in. diam. by 2.125 in. long and are provided with a short length of connecting cable—which also acts as balancing coil—and waterproofed flexible connectors of low contact resistance. K. D. Jacob 1

Heating effect and lag of small resistance thermometers. G. M. Dreosti. *Union S. Africa, Dept. Agr. Forestry, Rept. Low-Temp. Research Lab.* **1937–38**, 203–32 (1939).—The heating effect can be reduced considerably by making the coil former large and filling the free space in the thermometer with wax. Theoretical considerations of the choice of wire are indicated. The flow of heat is considered along theoretical lines and is shown to agree very well with the exptl. facts. K. D. Jacob 2

Metallic materials for thermocouples. A. Schulze. *J. Inst. Fuel* **12**, 41–8S(1939); cf. *C. A.* **33**, 6092⁶.—A review is given of the progress made in the use of thermocouples for temp. measurement, particularly for temp. greater than 1500°, and of the principles governing the choice of material for thermocouples. Data on the thermoelec. force and useful temp. range of a large no. of noble- and base-metal couples are included. B. C. P. A. 3

Modified aspirating thermocouple for [measurement of] gas temperatures. B. M. Larsen, G. Siddall and K. Heindlhofer. *J. Inst. Fuel* **12**, 55–6S(1939).—Constructional details are given for a suction pyrometer for gas temps. up to 1400° for which almost perfect radiation-shielding and negligible lag in following rapid temp. change are claimed. The radiation shield consists of a thick-walled cylinder of very porous insulating refractory into one end of which a no. of small gas channels are drilled. The pyrometer has been successfully employed in open-hearth checker chambers. B. C. P. A. 4

Theory and application of the suction pyrometer. A. Schack. *J. Inst. Fuel* **12**, 30–8S(1939).—A math. theory is developed for suction pyrometers of normal design, with 2 concentric suction tubes, and with several concentric rings of small suction tubes. Practical measurements in a flame-tube boiler showed that the results arrived at mathematically are borne out in practice, and that the theory may be used for the calcn. of corrections for high-temp. measurements. B. C. P. A. 5

Wall effect in gas-temperature measurements. C. H. Bosanquet. *J. Inst. Fuel* **12**, 14–17S(1939).—Errors in gas-temp. measurement due to radiation from the walls and to conduction along leads or sheaths are discussed and calcd. An estn. is made of the effect of shields and fins on the accuracy of measurement, and recommendations are made as to the best way of making these improvements. It is concluded that a bare fine-wire couple is the most satisfactory when conditions permit its use. B. C. P. A. 6

Application of temperature-measuring equipment to measurement of gas temperatures. S. Matthews. *J. Inst. Fuel* **12**, 72–5S(1939).—Recent developments in the field of industrial gas-temp. measurement are considered. Special attention is paid to problems relating to the use of radiation pyrometers. B. C. P. A. 7

Measurement of gas temperature in the chemical industry. J. C. Swallow. *J. Inst. Fuel* **12**, 68–72S(1939).—It is considered that the problem is one of maintenance rather than accuracy of measurement of temp. The relative merits of the various types of pyrometers are briefly reviewed. Attention is paid to problems of measuring gas temps. greater than 1200° and to the effects of sensitivity and lag on automatic temp. control. The relative durabilities of various refractory and metal protective sheaths are discussed. B. C. P. A. 8

Measurement of temperature of producer gas. M. W. Thring. *J. Inst. Fuel* **12**, 58–61S(1939).—Tests made on a brick-lined producer-gas main of 4 ft. diam., using 3 couples of diam. range 15:1 and a suction pyrometer, are described. Using a producer-gas temp. of 600°, the 3 couples gave readings within 12° of one another. Placing one of the couples in the shadow of another resulted in a considerable lengthening of the time to reach equil. Attention is drawn to the importance when measuring the temp. drop along a hot gas main of using a "control" couple to allow for fluctuations in the overall gas temp. with time. A fine-wire thermocouple, i. e., about 0.01 in. diameter, is considered to read about 6° less than the true temp. of producer gas in mains of the characteristics described. B. C. P. A. 9

Gas-temperature measurement in boilers. W. R. Hawthorne. *J. Inst. Fuel* **12**, 64–8S(1939).—Tests made in the gas passages of a H_2O-tube boiler on a rod-type sheathed couple, 3 bare-wire chromel/alumel couples of different wire sizes, a simple suction couple for temps. up to 1000°, a H_2O-cooled high-suction couple for higher temps., and a special "banjo" multiple Pt fine-wire couple with wire sizes varying from 0.02 to 0.004 in. diam. are described. It is considered that for practical purposes suction pyrometers combined with efficient ejectors are eminently suitably. B. C. P. A. 10

Errors in gas-temperature measurement. A. F. Webber. *J. Inst. Fuel* **12**, 56–8S(1939).—Two widely-different cases where a sheathed thermocouple failed to give correct temp. are quoted. In one of them, a hot-blast main at an ironworks, a substantial error was shown in conditions which should have favored accuracy, while in the other, a narrow H_2O-cooled flue, the error, though expected, was of unforeseen magnitude, viz., 540°. B. C. P. A. 11

Errors in gas-temperature measurement. R. I. Brown. *J. Inst. Fuel* **12**, 84–6S(1939).—A method of approximation for calcg. the correction to be applied to the reading of a thermocouple or suction pyrometer inserted in a gas stream is outlined. B. C. P. A. 12

Errors in gas-temperature measurement and their calculation. M. Fishenden and O. A. Saunders. *J. Inst. Fuel* **12**, 5–14S(1939).—Errors in measuring gas temp. by thermocouple or other inserted instrument are discussed. Simplified curves are given for estg. the error due to radiation between a thermocouple and surrounding walls, for shielded and unshielded couples of different size and emissivities. A table of emissivities is given, with numerical examples showing the use of the curves. Comparisons are made with actual practice. Curves are also given for estg. the errors due to time lag when measuring fluctuating gas temp., and for calcg. the error due to conduction of heat along the thermocouple leads. Some less common methods of gas-temp. measurement are briefly referred to. B. C. P. A. 13

Measurement of flame temperature. G. Ribaud, Y. Laure and H. Gaudry. *J. Inst. Fuel* **12**, 18–30S(1939).—The principles of the different methods of flame-temp. measurement are discussed. The suction pyrometer, extrapolation to zero-size method and the heated-wire methods are described. Optical methods for partly opaque luminous flames are considered (e. g., the Kurlbaum methods and its improvements), and also a photographic method. Nonluminous flames are discussed, particular attention being given to Féry's method of the inversion of the Na line, its errors and improvements. The problems of measuring fluctuating flame temp. and temp. in an internal-combustion engine are dealt with. Brief descriptions are given of a chemical and a thermal-cond. method. Féry's method is considered to be the most likely to lead to reliable results if proper precautions (described) are taken. B. C. P. A. 14

Optical temperature measurement of luminous hydrocarbon flames. G. Naeser. *J. Inst. Fuel* **12**, 38–41S (1939).—The principles of the color pyrometer are briefly discussed. A detailed description is given of the color-brightness pyrometer which by means of a simultaneous detn. of brightness in the sum of two colors (usually red and green) and the color from the ratio of the same two colors enables the true temp. of luminous flames having a continuous heat spectrum to be measured with a high degree of accuracy. A summary of various flame-temp. detns. made with this pyrometer is included. B. C. P. A. 15

Measurement of temperature in high-pressure con-

tainers. A. Michels and B. Blaisse. *J. Inst. Fuel* **12**, 49–54S(1939).—The effect of pressure on heat transfer is discussed. The various methods employed in practice are briefly described; they include; the thimble method, the use of expansion thermometers and of thermocouples and resistance thermometers, and the optical method. B. C. P. A. 1

Temperature measurements on liquid steel in the basic open-hearth process. Sven Fornander and Ture Omberg. *Jernkontorets Ann.* **123**, 527–44(1939).—A W-Mo thermocouple was constructed and enclosed in a water-cooled pipe with a large enough flow to keep the water temp. rise below 35°. To permit easy replacement the hot junction was inserted in a socket connecting with the cold junction. The hot junction was inserted in Pythagoras tubes and covered with a graphite-clay mixt. to prevent attack by slag and steel, and the whole junction protected against breakage by enclosure in a graphite tube. Temp. equil. was attained in 2.5–3 min. The junction was effective for about 6 measurements. The measured temps. varied considerably from the heat of the charge as estd. by the operators. The authors therefore believe that temp. control by such thermocouples should insure greater uniformity of production. H. C. Duus 2 3

Production of low temperatures—simplified and inexpensive laboratory procedure. Helen L. Wikoff, Benjamin R. Cohen and Morton I. Grossman. *Ind. Eng. Chem., Anal. Ed.* **12**, 92–4(1940).—The use of solid CO_2 and various solvents for producing low temps. was studied. By addn. of 115 to 170 g. of dry ice to 500 cc. of each of the following in a thermos bottle, the temp. indicated was held within 1 or 2° for 4 hrs.: $(CH_2OH)_2$ (I) −15°; dimethoxytetraethylene glycol (II) −31°; diethylcarbitol −52° (III); carbitol acetate (IV) −67°; cellosolve (V), cellosolve acetate (VI), diacetone alc. (VII), Bu cellosolve (VIII) −73 to −77°. Of these I–IV crystd. at the temps. indicated but V–VIII did not. III and VII were considered the most useful because they remain more fluid at low temps. W. F. Bruce 4 5

Calculation of heat exchangers and the use of adimensional characteristics in some thermal problems connected with chemical plants. B. Finzi-Contini. *Atti X° congr. intern. chim.* **4**, 304-12(1939).—The calcn. of heat exchanges between permanent currents, carried out by means of some adimensional parameters characteristic of the heat exchanger and its functioning, is described and compared with other methods. It is based on general graphs, two of which are reproduced in new suitable scales. This new method is considered particularly applicable in the field of chem. plants, partly because of the rapidity of the calcn. made possible and partly because it is suited to cases where the factors involved differ in various parts of the app. A. H. Krappe 6 7

Simply constructed vacuum oven. W. G. Whittleston. *New Zealand J. Sci. Tech.* **21B**, 165–7(1939).—A Cu vessel with a lid fitted with a gasket is heated by 2 nichrome spirals embedded in asbestos and paraffin wax. A Hg thermoregulator, thermometer and exhaust tube are admitted to the vessel through a rubber stopper. A modified Bunsen valve and a condenser are attached between the exhaust and a H_2O pump. The oven was found entirely reliable. W. F. Bruce 8

High-speed centrifugals (Hoyt, Smith) **28**. Distn. and distn. technique in perfume industry (Herold) **17**. Glass as chem. engineering material—filters (Quarendon) **19**. Adsorption apparatus. Pittsburgh Lectrodryer Corp. Brit. 508,372, June 22, 1939. App. for the treatment of gaseous fluids comprises a bed or beds of adsorptive materials subdivided into sectors or zones, chambers disposed above and below the bed(s), and a rotary cylindrical circumferentially ported valve extending through the bed (s) and adapted for supplying and delivering sep. streams of treatment and reactivation fluid to such chambers for their passage through the different zones or sectors in predetd. sequence and from the upper to the lower chambers and *vice versa*, so that the streams pass through the bed(s) in opposite directions.

Apparatus for carrying out endothermic reactions in the vapor and gas phases. M. A. Nechaev. Russ. 52,047, Oct. 31, 1937. Addn. to Russ. 45,709. Construction details.

pH meter. Donald K. Allison (to National Technical Laboratories). U. S. 2,183,531, Dec. 19. Various structural and operative details are described of a pH meter which includes: a housing and a head assocd. together and rotatable with respect to each other, the housing carrying one relative movable part of a potentiometer and the head carrying the other relatively movable part of the potentiometer so that rotation of the housing and head with respect to each other will vary the output of the potentiometer; a pair of terminals adapted to be connected to a pair of electrodes; a galvanometer; an electrical circuit connecting the potentiometer, galvanometer and terminals in such a manner that the output of the potentiometer can be balanced against the e. m. f. generated by the electrodes when they are in contact with a soln. whose pH is to be measured; and means for detg. the pH values as a function of the balanced output of the potentiometer. Cf. *C. A.* **34**, 5[6].

Siphon apparatus. Kenneth S. Smith and Ernest V. Casburn (to Eastman Kodak Co.). U. S. 2,184,025, Dec. 19. Various structural details.

Extensometer device suitable for testing various materials. Quintin M. Henderson (to United States Steel Corp.). U. S. 2,183,909, Dec. 19. Various structural, mech. and operative details.

Fractional distillation of liquid mixtures, especially petroleum. Antoine J. Brugma. Dutch 46,919, Oct. 16, 1939. A distn. column provided with one or more side streams is operated in a cycle: first a feeding period without any take-off, then a refluxing period without feeding or take-off, finally a take-off period during which products are removed from the column. Several variations are discussed. Less overlap of fractions is claimed.

Valve for controlling the flow of liquids or solids or their mixtures through pipe lines. Willing B. Foulke (to E. I. du Pont de Nemours & Co.). U. S. 2,183,835, Dec. 19. Various structural details, involving use of a flexible tube such as one of rubber and devices for its constriction.

Filters. Arthur H. Stevens. Brit. 508,514, July 3, 1939. A fluid-penetratable filter element comprises a relatively thin body consisting predominantly of fibers, the body being impregnated over the filtering area with a hardened resin having irreversible thermohardening characteristics similar to a $PhOH\text{-}CH_2O$ resin, the pores of the body being open for the passage of filtrate therethrough. An aldehyde resin may be applied to the fibers of the body in an unhardened condition and then hardened by polymerization. The body may consist of porous paper, asbestos fibers, cellulose fibers, etc.

Filtering apparatus. Henry C. A. Meyer (to United States Hoffman Machinery Corp.). U. S. 2,183,368, Dec. 12. Various structural, mech. and operative details. 1

Gas filters or cleaners. Hans Wittemeier. Brit. 508,475, June 28, 1939. In app. wherein a filter layer or layers, through which the gas is passed, is immersed in or arranged above a liquid bath and wherein the liquid under the influence of the gas flow is caused to irrigate the filter layer(s) to cleanse the same, the liquid is contained in 2 sep. chambers or in 1 chamber divided by a depending filter layer arranged between 2 nonpermeable walls into 2 compartments, the 2 chambers or compartments communicating below the level of the liquid, and the liquid in 1 chamber or compartment is subject to the pressure of the gas entering the filter and that in the other is subject to the pressure of the gas on the outlet side of the filter or to atm. pressure, whereby the greater the pressure difference, the greater the difference in level of the liquid in the chambers or compartments so that the tendency of the gas to entrain an increasing amt. of liquid with increasing gas velocities is reduced. 2

Apparatus suitable for filtering pulps and slurries. Theodore L. Genter (to Oliver United Filters Inc.). U. S. 2,184,451, Dec. 26. Various structural, mech. and operative details of filters of the disk type. 3

Strainer of the back-washing type for water, sewage, oil, gas, air, etc. Benjamin S. Burrell. U. S. 2,184,177, Dec. 19. Various structural, mech. and operative details. 4

Rotary apparatus for straining liquids. Daniel R. McNeal (to Andale Co.). U. S. 2,183,577-8, Dec. 19. Various structural, mech. and operative details.

Electromagnetic separators of the rotary drum type. Herbert H. Thompson, Alfred E. Davies and Henry E. Hutter. Brit. 508,300, June 23, 1939.

Gravity separation. Simon-Carves Ltd. and Geo. G. M. Carbert. Brit. 508,324, June 29, 1939. A mixt. of finely ground burnt pyrites and H_2O, with or without other substances, is used as a heavy sepg. medium for coal washing. The turbulence or rate of settlement may be regulated by an agitator running on a horizontal shaft. A portion of the liquid may be allowed to overflow with the products. Lime or soda may be added to the H_2O to neutralize any acid present in the burnt pyrites. 5

Separating gaseous mixtures. Isaac H. Levin. Brit. 508,685, June 28, 1939. A stream of the gaseous mixt. is subjected to cooling and expansion in an expansion engine, a further stream thereof is subjected to cooling and expansion by passage through an expansion valve, the 2 streams are then combined and the single stream formed is introduced into a rectifying column for distn. and rectification, the cooling, expansion and combining being effected in such manner that the unsatd. gaseous mixt. from the engine is satd. by the evapn. of some of the liquefied constituents of the stream issuing from the valve and the stream introduced into the column being composed of a satd. gaseous mixt. with particles of liquefied constituents of the gaseous mixt. The combined stream may be passed through a coil arranged about the base of the column prior to actual introduction into the column. The stream introduced into the column may be deflected to remove the liquid particles from the gaseous constituents before the latter pass into the distn. units of the column. 6 7 8

Separation of minerals, coal, etc. Leon Hoyois. U. S. 2,184,594, Dec. 26. App. is described, and various operative details of a process for treating materials in grains or pieces with currents of liquid such as water.

Apparatus for pneumatic separation of materials (such as coal and impurities) of different specific gravities and sizes. Frank F. Ridley (to Colliery Engineering Ltd.). U. S. 2,183,281, Dec. 12. Various structural, mech. and operative details. 9

Apparatus (with a rotary screening drum) for separating solid particles of different sizes, as in starch manufacture. Georg Jahn. U. S. 2,184,598, Dec. 26. Various structural, mech. and operative details.

Treating liquids containing suspended particles. Egon Hiedemann and Otto Brandt. Brit. 508,675, June 26, 1939. Solid or liquid suspended particles are removed from melts and liquids contg. them, or such melts and liquids are demixed into turbid and clarified liquids, by exciting the melt or liquid into short-wave vibrations by transmission through an elongated body thereof, and over the whole or substantially the whole of the cross section, of sound waves of about 8–100 kilocycles per sec. the wave form of which lies in or substantially in the longitudinal direction of the body of liquid, the length of the body being a multiple of its cross section so that any cavitation that may occur near the actual vibration generator does not hinder the coagulating effect of the vibrations. Cf. *C. A.* **33**, 10^8.

Apparatus suitable for taking samples of liquids such as crude oil from pipe lines. Ralph M. Slough (to Illinois Pipe Line Co.). U. S. 2,183,338, Dec. 12. Various structural and operative details.

Liquid dispensing valve suitable for use with various containers. Harry J. Meyer. U. S. 2,184,194, Dec. 19. Various structural details.

Apparatus for regulated feed of liquids, such as fuel charges for diesel engines. Merton J. Smith (30% to Paul B. Shannon, and 20% each to John P. Geiger and Robert W. Wilson). U. S. 2,183,875, Dec. 19. Various structural and operative details.

Electrical indicator and control apparatus for impurities in tank liquors of paper mills, dye works, water and sewerage plants, etc. Bjarne Pedersen. U. S. 2,183,584, Dec. 19. App. used comprises the combination of a coupling adapted to be attached to a tank contg. liquid, and into which coupling the liquid from the tank flows, and an elec. contact assembly including an insulating tube having a fluid-tight connection with the coupling at an angle which will permit the liquid to freely enter the end of the tube attached to the coupling, a conducting element fitted in the tube and extending throughout a part only of the length of the latter whereby an open space is left at one end of the tube to receive liquid from the coupling, an outwardly extending projection, and a cap having a hole therein through which the projection extends, said cap embracing the projection and attached to the tube for holding the conducting element and projection in elec. contact.

Vacuumizing containers such as jars by steam condensation. Edward M. Enkur and Louis L. Lauve (to Crown Cork & Seal Co.). U. S. 2,184,490, Dec. 26. Various details of app. and operation.

Method and apparatus for diffusion control. Lewis D. Drake. Brit. 508,385, June 30, 1939. A diffusion or *flotation* app. includes a vertically disposed deep tank, having an inlet and an outlet, for the reception of a liquid having solid matter suspended therein, the tank having impelling means therein for maintaining the liquid in continuous circulation with the solid matter in substantially uniform suspension, means for maintaining the level of the liquid in the tank above the impelling means, the latter being adjacent the surface of the liquid and above the major portion of the liquid, means coöperating with the impelling means for introducing a fluid, preferably a gas, to be diffused throughout the liquid, an elongated passage extending from the impelling means downwardly to a point adjacent the bottom of the tank to form a top diffusion zone above the liquid-impelling means, a small elongated zone of upward fast liquid movement in the passage and a larger zone of substantially uniform downward pulp movement outside of the passage, the larger zone contg. the major portion of the liquid and permitting small froth-forming gas bubbles held in the downwardly flowing column to assert their buoyancy to rise through the column and gather with the primary froth, the lower portion of the tank being formed to provide a lower pick-up zone of progressively increasing velocity to the tank bottom, from which the small zone of upward fast liquid movement returns the liquid to the impelling means for recirculation.

Mineral classifier machines. Clifton W. Livingston. Brit. 508,339, June 29, 1939. These comprise a tank, open at its top and provided with an inclined bottom, transverse partitions in the deeper part of the tank for the

division thereof into sorting zones and a washing and sorting column, an endless conveyor operating within the tank, 1 part of the conveyor being movable vertically in 1 sorting zone and another part movable parallel to the tank bottom, means for delivering material downwardly into the column, means for directing a current of liquid horizontally across the column and the material feed, a deflector to deflect the current upwardly, means to deflect the upwardly rising current from the column into the sorting zones and transverse overflow launders arranged at the open top of the tank in 1 of the sorting zones.

Gyratory crusher suitable for sand lumps, etc. Russell S. Ellis. U. S. 2,184,214, Dec. 19. Various structural, mech. and operative details.

Method and apparatus for briquetting fine-grained, pulverulent or dust-fine material. Fuel Improvement Co. Ltd. Brit. 508,343, June 29, 1939.

Bunsen burner. Roy C. Underwood. U. S. 2,184,203, Dec. 19. Various structural details.

Gas burner for producing temperatures above 1000°, as in chemical furnaces. Willibald Trinks (to Eastman Kodak Co.). U. S. 2,183,596, Dec. 19. Various structural details.

Mud guns for closing furnace tap-holes. Alfred Osolin and Jay Wesley Ferree. Brit. 508,655, July 4, 1939.

Shell-and-tube heat-exchange apparatus. Clarence D. Coulter and Edwin R. Cox (to Southwestern Engineering Co.). U. S. 2,183,160, Dec. 12. Various structural details.

Heat-exchange apparatus suitable for use with various kilns, blast furnaces, etc. Frank O. Campbell and Geo. W. Nigh. U. S. 2,183,956, Dec. 19. Various structural details.

Use of impact vibrations for cleaning coils of heat-exchanger tubes. Heinrich Peters (to La Mont Corp.). U. S. 2,183,496, Dec. 12. Various details of app. and operation for effecting dirt removal.

Belt pulley. Wm. B. Collier (to B. F. Goodrich Co.). U. S. 2,184,545, Dec. 26. To minimize belt-squeaking, a pulley having a supporting body of nonvitreous material such as steel, with a concentric portion of approx. belt-supporting size is provided with a thin, belt-contacting facing of vitreous material fused in place on this portion.

Pressure gage suitable for use with oils, acids, alkalies, etc. Frederick A. Barnes (to Bailey Meter Co.). U. S. 2,184,163, Dec. 19. Various structural, mech. and operative details.

Refrigerating apparatus suitable for use with ammonia. Clarence T. Sorensen. U. S. 2,184,322, Dec. 26. Various structural and operative details.

A hitherto unexplained phenomenon in the burial chamber of Tut-ench-amon. A. Tschirch. *Schweiz. Apoth.-Ztg.* **77**, 565(1939).—All objects in the tomb chamber including the stone sarcophagus were uniformly covered with a fine gray bloom. It has been shown (*C. A.* **6**, 2089; **22**, 4840) that upon autoxidation of oil of turpentine, 2 terpinoresenes are formed, both solid; *A* m. 106–7°, *B* m. 272°. In the chamber, these form the coating, caused by terpenes which are always present in essential oils. They had been added to the balsams that were used in the burial. The hot air of the chamber aided in volatilizing the terpenes, which then underwent autoxidation. S. Waldbott

Copper and bronze pieces in prehistoric collections. Wilhelm Witter. *Nachrichtenbl. deut. Vorzeit.* **13**, 237–8 (1937); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 731–2.—Analyses of pieces of broken needles found in the excavations at Gezer (Palestine) of 1000–1400 B. C. average, according as they are of the 1st, 2nd, 3rd or 4th Semitic period, resp., 77.90, 63.5, 66.4 and 90.0% Cu; 2.89, 3.7, 23.4 and 1.86% Zn; and 11.2, 33.7, 10.17 and 7.73% Sn. C. A. Silberrad

Physics for the year 1939. Alpheus W. Smith. *Ohio State Univ., Eng. Expt. Sta. News* **12**, No. 1, 22–4(1940). E. J. C.

Safety training of undergraduate chemical students. A. S. Zoerb. *Can. Chem. Process Inds.* **24**, 90(1940). W. H. Boynton

Development of the chemical laboratories, London County Council. D. C. Garratt. *Pharm. J.* **142**, 274–5 (1939). Historical, illustrated. Research on analytical methods and malt and oil tests are among special work taken up. S. Waldbott

A new approach to first-year chemistry. G. M. Schmeing. *Trans. Illinois State Acad. Sci.* **32**, No. 2, 127–8 (1939).—A precis of the newer theory of at. structure. J. H. Reedy

Techniques for large-group demonstrations. Nicholas D. Cheronis and Henrietta Freud. *Trans. Illinois State Acad. Sci.* **32**, No. 2, 100–1(1939).—The following app. for demonstrations before large groups are described: (1) A rack for large test tubes, illuminated by elec. lights and reflectors; (2) a flask equipped with Cu electrodes to show union of N and O at high temps.; (3) a model geyser, consisting of a 5-ft. vertical tube of sheet iron, heated at the bottom; (4) a long wire app. to illustrate the magnetic forces acting on a wire carrying an elec. current. A no. of simple expts. to be performed individually by nonprofessional students have been devised. J. H. Reedy

Quantitative estimations in the qualitative course. Elijah Swift, Jr. *Trans. Illinois State Acad. Sci.* **32**, No. 2, 130–1(1939).—Known solns. contg. 50 mg. of each ion of the group are analyzed, and the final tests retained as standards. Then the unknown is analyzed, and the amt. of each ion is estd. by comparison with the known standard. Fifty-six of the results fell within an error of 50%. The pedagogical advantages of this approach are pointed out. J. H. Reedy

Distribution of organic matter in marine sediments and its availability to further decomposition. D. Q. Anderson. *J. Marine Research, Sears Foundation Marine Research* **2**, 225–35(1939); cf. *C. A.* **28**, 6599[3]; **32**, 5438[3].—C and N contents and values for O consumed (per 1 g. C) during 15 days' exposure to aged O-satd. sea water were obtained for marine muds taken near the Massachusetts coast. The org. C varied from 4.5% in muds collected from Hadley Harbor to 0.10% at a considerable distance from land; the O consumption in 15 days varied from 1000 cc. to 0 cc., and the C/N ratio varied from 16.2 to 5.6. There is no correlation between the amt. of O consumed and the amt. of org. C present in the sediments except when the C is low. Generally the C became less available to oxidation at greater depths and greater distances from land. George Ayers

Practical photocolorimetry. I. Sorgato. *Chimica e industria* (Italy) **22**, 1–4(1940).—A summary with 49 references. A. W. Contieri

Methods and apparatus of the Physicochemical Bureau of Standards. XI. Purification and criteria of purity of organic standards. L. Gillo. *Bull. soc. chim. Belg.* 48, 341–443(1939); cf. *C. A.* **34**, 1530⁹.—A detailed, exptl. study of the literature of Et_2O (I), alc. (II), AcOEt (III) and CS_2 (IV) was made so that these compds. might be used as org. standards. Qual. and quant. methods are given for the detn. and removal of impurities in these compds. Two methods of purification of I are recommended: I is shaken with 50% H_2SO_4, distd., dried 8–15 days over $CaCl_2$ and 1 month over Na wire and distd., b_{760} 34.58–4.59°, d_0 0.73626; the second method requires washing with satd. $KMnO_4$ soln. contg. 5% NaOH prior to the above treatment and 2 months over Na in the absence of light and air. I purified by these 2 methods shows a b.-p. variation of 0.006–0.014° and a H_2O and AcH content of 0.0008–0.0010%; the amt. of $C_4H_{10}O_2$ per 100 cc. I is 10^{-3} g. and 5×10^{-5} to 10^{-4}%, resp. H_2O and AcH can be completely removed only by chem. means. I is best preserved by purification by the second method followed by storage in sealed containers contg. no air and light; P_2O_5 is a good preservative for I. By distg. 500 cc. II in a current of N with 75 cc. IV in all-glass app., 300 cc. of II is obtained b_{760} 78.30°, d_0 0.80624; this sample contains less than 0.0005–0.001% H_2O, 0.001% EtCOMe, 0.0005% MeOH, 0.0003% III, 0.004% AcH and 0.0001–0.0002% IV. II is freed from III by simple distn., from H_2O by azeotropic distn. with IV; AcH and especially MeOH are difficult to remove completely. III is dried over anhyd. K_2CO_3 for 2 months, filtered, distd. and the initial and final fractions are discarded; the product is redistd. in all-glass app. over P_2O_5 (10–20 g. per kg. of III) and after 10 cc. has distd., a product b_{760} 77.15 ± 0.01°, d_0 0.92451, is obtained. This contains less than 0.004% each of AcOH, alc. and H_2O. Data are given showing the instability and decompn. of III stored in darkness in the absence of air for 4, 6 and 13 yrs. IV is suitably purified by 3 distns. in all-glass app., b_{760} 46.25°, d_0 1.29268; it possesses a very weak odor, < 0.001% H_2O, < 5×10^{-6}% H_2S and S. IV is preserved well in darkness. 272 references. David E. Adelson

The atomic weight of holmium. O. Hönigschmid. *Naturwissenschaften* **27**, 855(1939).—By mass spectrography Ho was found free of isotopes and of mass 165, the chem. at. wt. being 164.94. With a Ho prepn. of high purity, having 0.013 at. % Y, 0.04 at. % Er, 0.03 at. % Dy analysis of the trichloride gave a corrected value for the at. wt. of 164.944. B. J. C. van der Hoeven

The atomic parameters of γ-silver-cadmium. Harald Perlitz and Rolf Aavakivi. *Acta Commentationes Univ. Tartu.* **1939**, No. 2, 13 pp.—See *C. A.* **34**, 1221¹. F. C. Nachod

The dielectric constants of ammonia, nitrogen and carbon dioxide at ultrahigh frequencies. Gerald W. Fox and Alden H. Ryan. *Phys. Rev.* **56**, 1132–6(1940).—The heterodyne beat method has been used to det. the dielec. consts. of N_2, CO_2 and NH_3 at a frequency of 56 megacycles in the temp. range of 22° to 45°. The consts. of N_2 and NH_3 at 56 megacycles agree well with the values found at low frequencies. For CO_2 an anomaly was observed, the value of the const. rising from its normal value to a max. at about 39° and then decreasing. This latter effect is discussed. Bernard Lewis

The elastic, dielectric and piezoelectric constants of heavy-water Rochelle salt. A. N. Holden and W. P. Mason. *Phys. Rev.* **57**, 54–6(1940); cf. *C. A.* **33**, 8073⁴.—Crystn. of Rochelle salt from heavy water raises the upper Curie point of the material by 11° and lowers the lower point by 5°, but leaves the other properties substantially unchanged. Bernard Lewis

Magnetism and molecular constitution of some manganese compounds. S. S. Bhatnagar, Brahm Prakash and Jai Chand Maheshwari. *Proc. Indian Acad. Sci.* **10A**, 150–5(1939).—In order to clarify certain questions relative to structure the susceptibilities of several complex Mn compds. were detd. by the Gouy method. The details of the prepn. of the compds. are given and the various formulas which have been suggested for them are discussed. The results of the magnetic measurements and the formulas that these results indicate are:

Name	Formula	Specific susceptibility	Temp.
Pink manganous chloride of pyridine	$C_5H_5NH.MnCl_3.H_2O$	55.80×10^{-6}	21°
Green manganous chloride of pyridine	$2C_5H_5NH.MnCl_4$	41.29	21°
K manganic chloride	$2KCl\ MnCl_4$	18.05	20°
Ag permanganate	$AgMnO_4$	− 0.28	27°
K manganic cyanide	$K_4[Mn(CN)_6]$	4.0 ± 1.0	20°

W. W. Stifler

Further measurements of the magnetic properties of some salts of the iron group at low temperatures. W. J. de Haas, B. H. Schultz and J. Koolhaas. *Physica* **7**, 57–69(1940)(in English); cf. *C. A.* **33**, 6670¹.—By use of the methods previously described, the susceptibilities of several Mn, Ni, Cr and Cu salts were measured at temps. down to 14°K. $MnSO_4$ follows the Curie-Weiss law with $\theta = -24°$ and the const. = 4.28. For MnI_2 the deviations from the Curie law are small down to 60° but at H temps. the $1/\chi - T$ graph is curved and the susceptibility is much smaller than that calcd. for the free Mn^{++} ion. The behavior of MnF_2 is similar to that of MnO. Its susceptibility is much less than that of the free Mn^{++} ion and it has a max. at about 70°K. The susceptibility is slightly dependent on field strength at H temps. The susceptibility of $MnBr_2$ is only a few % less than the theoretical value for the free Mn^{++} ion but apparently it follows neither the simple Curie nor the Curie-Weiss law. At H temps. the susceptibility depends slightly on the field strength and there is some evidence of remanence. The behavior of $NiCl_2$ is similar to that of $CoCl_2$ previously reported. It shows thermomagnetic remanence and a coercive force of 3500 to 5300 gausses. The susceptibility of NiF_2 at H temps. does not depend on the field strength. At H temps. and field strengths up to 5200 gausses the susceptibility of $Cr_2(SO_4)_3$ shows no anomalies. The susceptibility of $CrCl_3$ at the lower H temps. depends markedly on the field strength, and a complete hysteresis loop is given for this salt at 14.8°K. Between 53° and 360°K. the susceptibility of CuF_2 can be represented by $\chi = (0.0629/T) + 6.55 \times 10^{-4}$. At H temps. χ depends upon the field strength and is much smaller than for the free Cu^{++} ion. In $CuSO_4$ the susceptibility at H temps. depends upon the field strength for fields greater than 800 gausses. The paper includes tabulated results, graphs and details of prepn. of the salts. W. W. Stifler

Hall effect in ferromagnetic substances. V. Rudnitskiĭ. *J. Phys.* (U. S. S. R.) **1**, 247–50(1939).—See *C. A.* **33**, 7632⁴. A. D.

Crystal diamagnetism of tellurium. S. Ramachandra Rao and S. R. Govindarajan. *Proc. Indian Acad. Sci.* **10A**, 235–52(1939).—The principal diamagnetic susceptibilities of single crystals of Te, and of well-annealed polycryst. rods, were detd. by the Gouy method for various orientations throughout the temp. range 30° to 500°. At room temp. the susceptibility of the single crystal is −0.329 (× 10^{-6}) parallel to the trigonal axis and −0.296 perpendicular to it, which gives 1.11 as the magnetic anisotropy. The susceptibility of the annealed material is −0.307. Increase in temp. does not affect the susceptibility perpendicular to the trigonal axis but decreases the susceptibility parallel to it. At 220° the 2 become equal. On melting, the vol. susceptibility decreases from −1.7 to −0.3. The addn. of small amts. of Sn, Cd, Bi or Pb produces a decrease in both principal susceptibilities and in the magnetic anisotropy, which approaches unity. The diamagnetic susceptibility of polycryst. Te is also decreased by the presence of small amts. of these metals. The no. of valence electrons in the added metal does not seem to influence the magnitude of this effect, but the decrease in susceptibility is greater for elements of greater at. radius. Since the at. susceptibility of polycryst. Te is −39.2, whereas Kido gives −4.5 as the susceptibility of a g. ion of Te^{+6}, the 6 valence electrons must contribute −34.7 to the susceptibility. This is interpreted as indicating that Te behaves as a nonmetal, a conclusion which is confirmed by its large elec. resistance. The elec. and

thermal conductivities and the coeff. of linear expansion have different values parallel and perpendicular to the trigonal axis. W. W. Stifler

Paramagnetic relaxation in iron ammonium alum and in chromium potassium alum. F. K. du Pré. *Physica* **7**, 79–91(1940)(in English).—The mutual inductance bridge method, previously used for $GdSO_4$ (*C. A.* **34**, 10[7]), was applied to the study of $FeNH_4$ alum and CrK alum at liquid-He temps. This method consists essentially in measuring the differential susceptibility when a small oscillating field is superimposed upon a strong const. field in which the substance is placed. From the detailed results given, the relaxation time in a field of 1350 gausses for the $FeNH_4$ alum is calcd. as 0.0025 sec. at 4.218°K. and 0.0035 sec. at 3 490°K., while for the CrK alum it is 0.007 sec. at 3.50°K. and 0.018 sec. at 2.006°K. As these values are calcd. from small differences, they are accurate to within about 20%. W. W. Stifler

The paramagnetic susceptibility of copper-nickel and zinc-nickel alloys. Mary A. Wheeler. *Phys. Rev.* **56**, 1137–45(1939).—Alloys of Ni were prepd. with 0 to 60% Cu or 0 to 30% Zn. Their susceptibilities above their Curie temps. were measured as a function of the temps. with a Weiss-Foëx magnetic balance at a field of 11,000. The Weiss-Curie law holds only in restricted ranges of temp., the curve becoming concave toward the T axis at high temps., especially for the alloys of low Ni content. The susceptibility at a given temp. decreases less rapidly than linearly with percentage Cu or Zn added. B. Lewis

Further researches on paramagnetic dispersion. P. Teunissen and C. J. Gorter. *Physica* **7**, 33–44(1940)(in English); cf. *C. A.* **34**, 1526[4].—Detailed results of expts. on paramagnetic dispersion, similar to those already reported, are given for measurements on $Cr(NO_3)_3.9H_2O$ at 77.4° and 90.2°K., $Mn(NH_4)_2(SO_4)_2.6H_2O$ and $MnSO_4.4H_2O$ at 77.4, 90.2 and 290°K., $MnCl_2.4H_2O$ at 64.4°, 77.4°, 90.2° and 290°K. and $Fe(NO_3)_3.9H_2O$ at 64.4, 77.4 and 90.2°K. The hydrated manganous salts show a pos. effect even at room temp., but a concd. aq. soln. of $MnSO_4$ gave neg. results. In addn. to the tabulated data, 13 sets of curves and an energy-level diagram are given. In general, only the hydrated vanadous, chromic, manganous and ferric salts contg. either 21 or 23 electrons per ion show a pos. effect. W. W. Stifler

The antiferromagnetic transition point of vanadium dioxide. H. Dressnandt and W. Schottky. *Naturwissenschaften* **27**, 840(1939).—A discussion of factors involved in the magnetic transition point from weak to strong paramagnetism of VO_2 (Klemm and Grimm, *C. A.* **34**, 1889[9]). It is assumed that only 2 V atoms are involved in the spin adjustment. B. J. C. van der Hoeven

Dipole moment of cedrene. Syu Kanbara. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 314–15(1939).—Cedrene, prepd. from cedar oil, b_{760} 262° (corr.), and has n_α^{15} 1.5042 and d_5^{15} 0.94458. The dielec. consts., ns and ds. for the temps. noted are: 3.263, 1.5042, 0.94458, 15°; 3.272, 1.5022, 0.94104, 20°; 3.273, 1.5006, 0.93744, 25°; 3.273, 1.4985, 0.93384, 30°; and 3.267, 1.4965, 0.93026, 35°. The dipole moment is 0.38×10^{-18} e. s. u. Cedrene is a suitable solvent for the study of the dielec. properties of vulcanized rubber. George Ayers

The torsional flexibility of aliphatic chain molecules. Alex Müller. *Proc. Roy. Soc.* (London) **A174**, 137–44(1940).—A series of measurements is made of the dielec. polarization of 2 di-ketones: (I) $C_{10}H_{18}O_2$, m. 63.5° and (II) $C_{11}H_{20}O_2$, m. 67.5°; they consist of aliphatic chain mols., each carrying 2 C-O dipoles differently situated in the mol. In I the 2 dipoles are antiparallel and tend to neutralize each other; in II they are on the same side of the chain axis and therefore reinforce each other. From the behavior of I and II in the neighborhood of their m. ps. M. concludes that even comparatively short chains suffer considerable distortion under the influence of temp., which suggests a modification of the view that the increase of the apparent symmetry of chain substances near their m. p. is due to the rotation of the mol. as a whole, as this increase may just as likely be due to internal distortion of the chains. Frank Gonet

Nomograms for calculating the conversion of carbon monoxide. N. M. Zhavoronkov and S. N. Tikhmenev. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 35–6(1939). H. M. Leicester

Measurements of the absorption of sound in oxygen and in carbon dioxide containing small quantities of water, deuterium oxide and neon—relaxation times for the vibrational energy. A. van Itterbeek and P. Mariëns. *Physica* **7**, 125–30(1940)(in English).—Previously reported measurements (cf. *C. A.* **33**, 6671[8]) are expanded to det. them as a function of temp. It was found that β-CO_2-D_2O/β-CO_2-H_2O is equal to about 1.5 and that this ratio is nearly independent of the temp. Measurements were also made on CO_2 gas to which a small amt. of Ne was added. A small excitation of CO_2 by Ne was observed. Measurements were made on the absorption of sound in O_2 between 50° and 150°. The relaxation times are computed. M. McMahon

The determination of the heat capacity of gases at high pressure. A. A. Matveenko. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 23–6(1939).—Equations are derived for calcg. the coeff. of compressibility of H, N, CH_4 and H-N mixts. by extrapolation to high temp., and from these, equations for detg. C_p are derived. H. M. Leicester

Viscosity of hydrogen vapor. W. H. Keesom and P. H. Keesom. *Physica* **7**, 29–32(1940)(in English).—From 14 to 20.5°K. the viscosity follows the equations: $\eta = (0.584\ T - 0.55) \times 10^{-6}$ poise. Gregg M. Evans

Effusion phenomena in relativistic quantum statistics. D. V. Gogate. *Phil. Mag.* **29**, 85–92(1940).—Recently Srivastava derived expressions for the no. and mass of particles effusing through a narrow orifice, for an ideal gas, taking account of quantum statistics (*Proc. Roy. Soc.* (London) **A167**, 516–26(1938)). In the present paper expressions are derived for the amt. of energy effusing through an orifice for various cases of nondegeneracy and of degeneracy. The passage of an ideal gas through an orifice is treated, account being taken of relativistic mechanics. In nondegenerate matter the amt. of energy effusing per sec. per unit of area is calcd. The effusion energy is also calcd. for a gas completely degenerate in the sense of the Fermi-Dirac statistics. In complete degeneracy the same expression holds for the rate of effusion of mass throughout the whole region from completely relativistic to completely nonrelativistic. Results are given graphically to illustrate the phys. significance of the equations that are derived. S. Tolansky

Free discharge of fluids through small circular orifices. Hira Lal Roy and Nirmal K. Sen-Gupta. *Ind Eng. Chem.* **32**, 288–90(1940).—In the standard orifice equation, $u = C\sqrt{2gh}$ (Badger and McCabe, "*Elements of Chemical Engineering*," 49 (1936)), values of C (0.080 to 0.938) are detd. for water and 4 oils of viscosities from 60 to 700 centipoises, through sharp-edged orifices from $^3/_8$ to $^1/_{16}$ in. diam. (heads of 2 to 6 ft. are used). Temp., d., surface tensions, viscosities, velocities and Reynolds nos. (0.6 to 51,000) are also tabulated, and C is plotted against Reynolds no. for each diam. For every liquid there is a crit. diam. and a crit. head, below which C decreases with decreasing head and diam., and above which it increases. For water, C increases with these; for the other liquids, C decreases with decreasing diam. Nine references. R. W. Higbie

Experimental investigations on the flow of liquids in tubes of very small diameter. J. M. L. Poiseuille. *Rheol. Mem.* **1**, No. 1, 1–101(1940).—This work, done 100 years ago, was reported *in extenso* in the *Mém. savants étrangers* in 2 papers. Since the 2nd of these papers is fundamental in the development of rheology it is given in full, with biographical and critical notes. E. C. Bingham

Effect of temperature and specific volume on the viscosity of liquids. III. W. R. van Wijk, J. H. van der Veen, H. C. Brinkman and W. A. Seeder. *Physica* **7**, 45–6(1940)(in English); cf. *C. A.* **33**, 3648[9].—Results of measurements at 1500 atm. and from 0 to 150° are shown tabularly and graphically for C_3H_8, $C(CH_3)_4$, CCl_4 and n-$C_{15}H_{37}OH$. Gregg M. Evans

Outgassing of water by use of ultrasonics. P. G. Paunov. *Ann. univ. Sofia. II. Faculté phys.-math.*, Livre 1, **35**, 179–202(in German, 203–5)(1938–39).—Under the influence of ultrasonic frequencies the amts. of absorbed gas decrease to approx. 50% of the original amt. This is explained by the assumption of standing waves in the water, undergoing no change in gas concn. in the nodes, but with the antinodes completely outgassed. 1

Gregg M. Evans

The measurement of the frequency of formation of crystal nuclei in undercooled melts. I. N. Stranski. *Ann. univ. Sofia. II. Faculté phys.-math.*, Livre 2, **34**, 303–4(in German, 305)(1937–38).—The method of observation is described. The melt is subjected to high pressure, while the walls of the vessel are heated to avoid formation of nuclei on the walls. Since the rise in temp. of the melt can be exactly calcd. thermodynamically as a result of the adiabatic compression, the existing undercooling can be detd. 2 3

A. H. Krappe

Vapor tension and grain size. D. Balarev and N. Kolarov. *Ann. univ. Sofia. II. Faculté phys.-math.*, Livre 2, **34**, 231–6(in German, 237)(1937–38).—Detn. of the quantity of NaCl and KBr crystal powders evapd. during grinding at a given temp. for varying lengths of time led to conclusions about the vapor tension of the powders at the temp. in question. In spite of the increase in no. of the very small crystals, with a corresponding increase in surface, the curve vapor tension *vs.* dimensions of the particles reaches a min. between 2 and 4 μ. 4

A. H. Krappe

Vapor pressure of hydrated crystals of oxalic acid and sodium formate. Sotozi Takagi and Seisi Oomi. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 302–4(1939).—By using a modification of Chadwick and Palkin's manometer (*C. A.* **32**, 6508[2]) and di-Bu phthalate, the vapor pressures of $H_2C_2O_4.2H_2O$ were detd. as follows (mm., °C.): 0.35, 0°; 0.91, 10.0°; 1.84, 20.0°; 3.78, 30.0°; 7.79, 40.0°; and 15.58, 50.0°. These may be represented by the equation $\log p = -(2765.64)(1/T) + 9.7130$. Addnl. equations of the Baxter-Antoine and Kirchhoff types are also given. For $HCO_2Na.3H_2O$, the vapor pressures are: 3.12, 0.1°; 4.48, 4.9°; 6.02, 9.8°; 6.10, 10.0°; and 7.92, 15.0°. These are represented by the equation $p = 3.125 + 0.2488t + 0.0047t^2$ and less well by an equation of the Clausius type. For $HCO_2Na.2H_2O$, the vapor pressures are: 1.60, 0.0°; 2.69, 4.9°; 3.17, 7.0°; 3.95, 9.8°; 5.90, 15.0°; 8.71, 20.0°; 11.74, 24.1°; and 14.60, 27.2°. These are represented by $\log p = -(2840.35)(1/T) + 10.6294$. The accuracy of the vapor pressure measurements was ±0.02 mm. Transition points for the hydrates of HCO_2Na occur at 15.3° and 27.9°. Values of $\Delta F°$ (cal.), $\Delta H_{298}°$ (cal.) and $\Delta S_{298}°$ (E. U.) for the resp. dissocn. reactions are: $H_2C_2O_4.2H_2O = H_2C_2O_4 + 2H_2O(g)$, 4940, 25,299 and 68.32 (values derived from the Baxter-Antoine and Kirchhoff formulas are less reliable); $HCO_2Na.3H_2O = HCO_2Na.2H_2O + H_2O(g)$, 2345.4, 9853.5 and 25.20; $HCO_2Na.2H_2O = HCO_2Na + 2H_2O(g)$, 4852.77, 25,982.10 and 70.88. 5 6 7

Conductivity measurements on potassium halides. Cornelius J. Brennecke. *J. Applied Phys.* **11**, 202–7 (1940).—Measurements were made on flat crystal plates of KBr and KCl, at 25–600° and under stresses of 0.05–0.90 kv./cm. The resistivities fell from about 10^{17} ohm-cm. at room temp. to less than 10^7 for KBr and less than 10^8 for KCl at the highest temp. Ohm's law held for cold cond. measured after preliminary heating. The current decayed exponentially with time at low temps., but remained almost const. at high temps. Cond. and temp. are exponentially related for both KBr and KCl, but for KCl an abrupt change in the slope of the curve was found between 200 and 250°. 9

S. L. Gerhard

Studies on the role of mode of formation and preliminary treatment in the estimation of the chemical activity of some technically important preparations. I. Hahn's emanation method as an aid in the study of the structural synthesis and transformation of solid substances. Robert Jagitsch. *Iva* **1939**, 170–7; cf. H., *C. A.* **23**, 5381.—A review with 36 references. **II. Discontinuous changes of faulty structural condition or of particle mobility and their influence on the reactivity of copper sulfide.** J. Arvid Hedvall, E. Brazee and R. Jagitsch. *Ibid.* 177–82.—X-ray studies of Cu_2S (I) with a Heiz camera show that between 100 and 400° no crystallographic change takes place. At 370° I in a current of O suddenly oxidizes with development of heat; a violent reaction also occurs at 460°. Studies by the emanation method (cf. Hahn, *C. A.* **29**, 396[7]) reveal that both temp. regions are characterized by changes in the arrangement state of I. Emanation power-temp. curves are given to show the changes at the 2 temps.

W. J. Peterson

The structure of real crystal systems and the problem of thermo-, tribo- and crystalloluminescence. D. Balarev, N. Kolarov, G. Georgiev and V. Ivanov. *Ann. univ. Sofia. II. Faculté phys.-math.*, Livre 2, **34**, 355–68(in German, 369–71)(1937–38).—The 2 fundamental assumptions in the author's theory of the structure of real crystal systems were tested experimentally, viz., (1) the thermodynamic bases of the disperse structure of the system and (2) the possibility that certain surface disturbances make themselves felt far in the interior of the system. (1) By detg. the initial temp. of gray heat (I) of $CaCO_3$ heated for various durations it was found that the temp. is lower after a short heating of the prepn. and higher at longer heating than in the original non-heated prepn. The curve: decompn. temp.-duration of heating of the pptd. $CaCO_3$ agrees with this result. (2) The 2nd assumption was confirmed by the detn. of I of the mixts. of $CaCO_3$-MoO_3 and $CaCO_3$-WO_3 and by the fact that I of the former mixts. falls below I of the individual components, whereas there are mixts. of $CaCO_3$ and WO_3 whose I is lower than those of $CaCO_3$ and WO_3. The expts. also brought out the fact that the curve of duration of grinding *vs.* I of all crystal powders examd. has a min. On the basis of the 2 assumptions the tribo- and the crystalloluminescence are explained by aging of the freshly ground crystal powders or of the freshly split-off surfaces or by the aging of the freshly pptd. systems. Thermoluminescence is explained by the approach of a crystal system which at ordinary temp. is in equil. with its surroundings to a crystal system in an equil. corresponding to the higher temp.

A. H. Krappe

Inner adsorption in salt crystals. VII. The upper limit of the quantity of salt adsorbed internally. D. Balarev. *Z. anal. Chem.* **118**, 411–15(1940); cf. *C. A.* **33**, 2012[5].—Expts. with solns. contg. H_2SO_4, KCl, NH_4Cl, $FeCl_3$ and sometimes $Ce(SO_4)_2$ showed that the adsorbed salt inside crystals of $BaSO_4$ can reach as high as 37 mol. % but the high content of foreign salt within a crystal is no proof that the two components form solid solns.

W. T. H.

Surface diffusion on polycrystals and the processes of staining of minerals. E. A. Nikiforov. *Trudy Tsentral. Nauch.-Issledovatel. Lab. Kamneĭ Samotsvetov Tr. "Russkie Samotsvety"* **1938**, No. 4, 18–30; *Khim. Referat. Zhur.* **2**, No. 5, 29–30(1939); cf. *C. A.* **33**, 4845[8].—Methods are given for accelerated staining of agate and polycryst. quartz ("belorechit"). The different adsorption processes on polycryst. surfaces are: (1) Adsorption of ions from solns. of salts retained on the mineral surfaces by electrostatic forces (the edges and the corners of the grains are the most active parts). (2) Adsorption caused by attraction of the dipoles. The peripheric dipoles (water, alcs., phenols) are most active. (3) Adsorption caused by the electrostatic polarization and by van der Waals forces (active in crevices and in re-entering angles). The usual process of staining of agate and of "belorechit" to a yellow color with a $Fe(NO_3)_3.9H_2O$ soln. takes place as follows: From the surface diffusion on quartz grains a film of water dipoles is formed which rapidly sats. the mineral. The

$Fe(NO_3)_3$ mols. penetrate the pores slowly, and the fixing of the polarized mols. on the surfaces can take place only by the replacement of the water dipoles previously adsorbed. A considerably faster method for the penetration of the stain is proposed by N. (the "topodiffusion method"). Sat. the sample of agate or of "belorechit" in water, fuse a layer of anhyd. $Fe(NO_3)_3$ on the surface of the sample and immerse it in benzene. The hydration process taking place on the contact surface of the melt with dipoles of water formed on the grain surfaces causes a "neg." diffusion (extn. of water from the pores of the mineral) and a "pos." diffusion of the $Fe(NO_3)_3$ mols. to dipoles of water adsorbed on the grain surfaces. This accelerates the process of vol. staining of "belorechit" to several hrs. instead of a month. Methylene blue was introduced by the same method in 1–2 hrs. "Belorechit" stained with methylene blue did not change its color even in hot concd. acids. The black color of agate (satd. with water) was obtained in several hrs. by the introduction of phenol by means of the dehydrating action of H_2SO_4.
W. R. Henn

Effect of dyes on the crystal habit and optics of NaF, LiF, NaCl, KCl, KBr and KI. Clifford Frondel. *Am. Mineral.* **25**, 91–110(1940).—These salts were crystd from solns. contg. various dyes (112 were tried with NaF); in most cases the dye, if adsorbed at all, is adsorbed on (100) and thus does not alter the normal cubic crystal habit. In a few cases adsorption occurs on (111) and the resulting crystal habit is octahedral. 107 references.
C. H. H.

The sintering of magnesia. Giovanni Malquori and Vittorio Cirilli. *Ricerca sci.* **10**, 905–14(1939).—The effect exerted by various closely related oxides on the thermal sintering of MgO was examd. The behavior of the following substances and systems was studied: Fe_2O_3, Al_2O_3, SiO_2, CaO, Fe_2O_3–CaO, Fe_2O_3–SiO_2, SiO_2–CaO, Al_2O_3–CaO, Fe_2O_3–CaO–SiO_2, since these substances are most frequently present as impurities in oxides that result from the thermal decompn. of natural magnesites. The conclusions are based on x-ray diagrams obtained with the Laue method and Cu-*K* radiation. F. C. N.

A study of oxide films on light metals by electron diffraction—magnesium, aluminum and beryllium. Sigeto Yamaguti. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 463–70(1939).—Pure Mg was polished with a coarse sandpaper ("Riken Corundum") and exposed for one day in the open air at room temp. The electron-diffraction pattern obtained corresponds exactly with that for the hexagonal system, showing the existence of pure Mg. A 2nd specimen was heated for 10 hrs. in the open air in an elec. furnace at 100°, a 3rd one for 4 hrs. at 200°, a 4th one for 2 hrs. at 300° and a 5th one for 1 hr. at 400°. After these samples were cooled, diffraction photographs were taken. The pattern of the 2nd sample corresponded with that of pure Mg, while those of the 3rd and 4th showed a mixt. of MgO and Mg to be present. The pattern of the last specimen corresponded with that of MgO. The rings observed further indicated the formation at ordinary temps. of a film of MgO of thickness about 10 A. Electron-diffraction photographs were taken of Al trenched with a glass cutter and left in the air for 10 days, and of 2 samples treated at 400° and 500°, resp. In the range between room temp. and 400° the existence of γ-Al_2O_3 (cubic system) could be shown. Between 400 and 500° there is a transition point for γ- and α-Al_2O_3 (hexagonal system). It was not directly possible to verify whether Be exposed to the air at ordinary temp. was covered with its oxide. At 400° a Be film was found. At 800° its thickness was greater than at 400°. Robert Simha

Hydration of tricalcium silicate. O. E. Radczewski, H. O. Müller and W. Eitel. *Naturwissenschaften* **27**, 807 (1939).—The hydration of $3CaO.SiO_2$ was followed in a Siemens supermicroscope (electron microscope) and photographs are reproduced (31,000 and 100,000:1). After shaking air-dry $3CaO.SiO_2$ for 2 hrs. with water, $Ca(OH)_2$ spherolites 0.2–1 μ in size appeared. If the hydration took place in an iso-BuOH-H_2O mixt. contg. 18% H_2O, the $Ca(OH)_2$ hemispheres 0.1–0.2 μ in size appeared and disk-shaped $Ca(OH)_2$ particles, 70–100 mμ, were also visible. Needles and spindle-like crystals of Ca hydrosilicate, with typically frayed ends of the spindles, were also found. B. J. C. van der Hoeven

The hydration of tricalcium aluminate. O. E. Radczewski, H. O. Müller and W. Eitel. *Naturwissenschaften* **27**, 837–8(1939).—The hydration of $3CaO.Al_2O_3$ was followed in an electron microscope. The fine-grained, air-dry powder shaken in water for 16 hrs. showed relatively large hexagonal plates of $3CaO.Al_2O_3.12H_2O$, 1.3×0.9 μ, 0.05–0.1 μ thick. In an iso-BuOH-H_2O mixt. contg. 18% H_2O the hydration at room temp. produced spherical structures, icositetrahedra of the more stable $3CaO.Al_2O_3.6H_2O$, 60–130 mμ in diam., sometimes only 30 mμ; occasional sharp-edged plates were formed. B. J. C. v. d. H.

The nature of certain intermetallic lattices. A. L. Norbury. *J. Inst. Metals* **65**, Advance copy, No. 858, 24 pp.(1939).—The theory is developed of "basic" body-centered cubic, close-packed hexagonal, and NiAs-type intermetallic lattices forming subsidiary lattices by the replacement of electrons by atoms or atoms by electrons. The electron-atom ratios of *3e*:*2a* for body-centered cubic, *7e*:*4a* close-packed hexagonal and *5e*:*2a* for NiAs-type lattices are enlarged upon to explain ratios such as γ-brass *83e*:*52a*, which is broken down to 27 (*3e*:*2a*) + *2e*−*2a* with 52 atoms to the unit cell. This operation is similarly performed for γ_1- and γ_2-brass, ζ_2- and η_2-CuAl and $CuAl_2$, all of the body-centered cubic lattice type. A similar procedure is followed with ζ-AgZn and Co_2Al_5, subsidiaries of ϵ-brass (*7e*:*4a*) close-packed hexagonal; and γ'-CoSn, PtPb, η-CuSn and FeS subsidiaries of the basic NiAs type (*5e*:*2a*) lattice. 29 references. J. N. Lynn

X-ray investigation of the transformation of γ-aluminum oxide into α-aluminum oxide. O. E. Gorbunova and L. I. Vaganova. *Trudy Tsentral. Nauch.-Issledovatel. Lab. Kamnei Samotsvetov Tr.* "*Russkie Samotsvety*" **1938**, No. 4, 66–7; *Khim. Referat. Zhur.* **2**, No. 5, 31–2(1939).—It was detd. from Debye diagrams that the powder obtained by roasting the NH_4 alums at 1100° consists exclusively of the γ-modification of Al_2O_3 and the powder obtained by roasting at 1200° consists exclusively of the α-modification. The Debye diagrams of the powder roasted at 1150° show lines of both modifications. The transformation of the γ-modification of Al_2O_3 into the α-modification takes place at 1150–1200°. W. R. Henn

Crystalline modification of alumina. I. Inversion of crystalline form of aluminum hydroxide by heating. Kei-iti Akiyama. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 394–5(1939).—X-ray analysis studies indicate that Al_2O_3, prepd. by heating $Al(OH)_3$ (obtained from $AlCl_3$ and NH_4OH) to temps. below 1100°, has the γ-form, and that Al_2O_3 heated above 1200° has the α-form. **II. Influence of CaO, MgO, Li_2O, Na_2O and K_2O on crystal inversion of alumina.** *Ibid.* 395–6.—Portions of γ-Al_2O_3 were heated 2 hrs. at 1700° with each of the following: 3, 5 and 7% of CaO; 3, 5 and 7% of MgO; 1.2, 2 and 4% of Li_2CO_3, calcd. as Li_2O; 3% of Na_2CO_3, calcd. as Na_2O; and 3% of K_2CO_3, calcd. as K_2O. X-ray data indicate that Al_2O_3 heated with more than 5% of CaO had the β-form and that Al_2O_3 heated with more than 3% of MgO and 2% of Li_2O had the ζ-form. This shows that β- and ζ-Al_2O_3 are actual modifications of Al_2O_3 and not alkali aluminate and Li aluminate, resp. G. A.

Crystallographic modification of aluminum oxide. A. S. Ivanov. *Trudy Tsentral. Nauch.-Issledovatel. Lab. Kamnei Samotsvetov Tr.* "*Russkie Samotsvety*" **1938**, No. 4, 44–58; *Khim. Referat. Zhur.* **2**, No. 5, 31(1939).—A review of literature useful for the synthesis of corundum. Data are given for all known modifications of Al_2O_3 with references for each modification separately.

Comparative x-ray studies of arsenates and selenates. P. Kokkoros. *Praktika Akad. Athenon* **13**, 337–44(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 252–3.—Scorodite ($FeAsO_4.2H_2O$) has *a* 8.92, *b* 10.30, *c* 10.01 A.; strengite ($FePO_4.2H_2O$) *a* 8.65, *b* 10.06, *c* 9.84 A.; both have 8 mols. in the unit cell, space group V^{15}_h. $CdSeO_4.2H_2O$ has *a* 10.42, *b* 10.71, *c* 9.36 A.; $MnSeO_4.2H_2O$ *a*

10.47, *b* 10.51, *c* 9.24 A.; both also have 8 mols. in the unit cell. C. A. Silberrad

The nature of the anomalies of some properties of Rochelle salt and its relation to polymorphism. R. D. Shul'vas-Sorokina. *J. Phys.* (U. S. S. R.) **1**, 299–307 (1939).—See *C. A.* **33**, 5255[5]. E. H.

Crystal structure of sodium glycerophosphates. Carlo Minguzzi. *Periodico mineral.* (Rome) **9**, 347–57(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 428.—The α and β forms of the Na glycerophosphates, $CH_2OHCHOH\text{-}CH_2OPO_3Na_2.6H_2O$ (α) and $CH_2OHCHOPO_3Na_2CH_2OH$ (β) have (α) $a:b:c$ = 1.0980:1:1.09522, β 106° 15′, n_α 1.444, n_β 1.455, n_γ 1.468, d_{20} 1.634; and (β) $a:b:c$ = 0.66559:1:0.51618, β 106° 50′, n_α 1.474, n_β 1.489, n_γ 1.499 d_{20} 1.718. Both are colorless and monoclinic. Cf. Bailly, *C. A.* **32**, 7018[8]. C. A. Silberrad

Crystal structure of the dioxime of 1,3-dibenzoylpropane. Edoardo Sanero and Mario Fornaseri. *Periodico mineral.* (Rome) **9**, 213–22(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 432.—$PhC(:NOH)(CH_2)_2C(:NOH)Ph$ is tetragonal with *a* 9.46, *c* 32.26, and 8 mols. in the unit cell, space group $D_{4h}^1 - P\ 4/mmm$ or $D_{4h}^4 - P\ 4/nmm$, n_ω 1.698, n_ϵ 1.597. C. A. Silberrad

The unit cell and space group of β-octamethylcellobiose and β-hendecamethylcellotriose. Tatuo Ohasi. *Bull. Chem. Soc. Japan* **14**, 517–20(1939).—The dimensions of the rhombic unit cells of β-octamethylcellobiose and β-hendecamethylcellotriose detd. by x-ray analysis are: *a* 12.0, *b* 43.7, *c* 4.50 and *a* 21.3, *b* 34.5, *c* 4.50 A., resp. Both substances have a rhombic crystal lattice and possess the corresponding space group $D_2^1 - P\ 2_12_12_1$, with 4 mols. in one unit. The reported results do not agree with the work of Trogus and Hess (*C. A.* **26**, 5257; **29**, 6813[6]). Frederick C. Nachod

Measurements of the adsorption of different gases on copper at liquid oxygen and hydrogen temperatures, with low pressures. J. Borghs and A. van Itterbeek. *Physica* **7**, 17–28(1940)(in English).—Interpretation of results could be made on the basis of Polanyi's theory, the ratio of any two potential functions being proportional to the square roots of the van der Waals const. The cc. of gas adsorbed per sq. m. of surface exceeds 7 for N, 11 for Ne and 14 for H. The adsorption of H is non-reversible. Gregg M. Evans

The adsorption of potential-determining ions. III. Adsorption of acids, neutral salts and bases on highly activated carbon in absence and presence of hydrogen and oxygen. Albin Kellermann and Erich Lange. *Kolloid-Z.* **90**, 89–104(1940); cf. *C. A.* **34**, 28[2].—A review with 94 references. G. G.

Adsorption of electrolytes on silicic acid on sesquioxides, and on their mixtures. V. A. Kargin. *Uspekhi Khim.* **8**, 908–1019(1939).—Data are given on the adsorption of $AgNO_3$, $Ca(OH)_2$, NaOH, KOH, NH_4OH, HCl, H_2SO_4, H_3PO_4 and various salts on SiO_2, Fe_2O_3, Al_2O_3 and various SiO_2-M_2O_3 mixts. Adsorption of Al_2O_3 and H_2SO_4 proceeds in a 2:1 ratio; of Ag^+ and SO_4^{--} in equiv. ratios. The *absorption spectra* of adsorbed colored salts are discussed. F. H. Rathmann

Adsorptive power of coagulates obtained from aqueous tannin solutions. G. Rossi. *Atti X° congr. intern. chim.* **4**, 890–4(1939).—Great variations are shown in the adsorption of various coloring substances resulting from changes in the tannin concn., the quantity of the coagulation and even from changes in the coagulants. In 100 cc. of gelatin + K alum soln., the mg. of methylene blue adsorbed varied from 7.046 with 4 mg. tannin to 17.598 for 48 mg. tannin. In 100 cc. of Pb acetate soln., the mg. of methylene blue, phenosafranine and fuchsin absorbed varied from 5.183, 8.849 and 6.000, resp., for 20 mg. tannin to 9.901, 17.792 and 15.334, resp., for 240 mg. tannin. A. H. Krappe

Adsorption of ions on polar adsorbents as a function of the reaction medium. II. Adsorption from mixtures of multivalent anions on ferric hydroxide as a function of the concentration of alkali. Gr. Bălănescu and Vintilă T. Ionescu. *Bul. Soc. Chim. Romania* **20A**, 139–83(1938); cf. *C. A.* **33**, 219.—Adsorption on polar $Fe(OH)_3$ and in the presence of various amts. of NH_3 was studied with mixts. contg. different ratios of two anions. The mixts. used contained: phosphate ions with arsenate, citrate, sulfate or oxalate ions; arsenate with sulfate or oxalate; oxalate with citrate or sulfate. III. **Discussion and interpretation of the results.** *Ibid.*[3] 185–95.—The observed phenomena are complex and detd. by the nature of the reaction medium. If the latter is acidic, neutral or basic compds. are formed. For a basic medium, adsorption is governed by a surface reaction. Anions are replaced by OH ions in the decreasing order: sulfate, oxalate, citrate, arsenate, phosphate. G. M. Murphy

Physical chemistry of surface phenomena and of dispersed systems, and their application in U. S. S. R. P. A. Rebinder. *Sbornik "Matematika i Estestvozn. v S. S. S. R."* **1938**, 431–64; *Khim. Referat. Zhur.* **2**, No. 5, 16 (1939).—The importance of the properties of the phase surfaces, suspensions, foams, fogs, emulsions, etc., as well as numerous technical applications of these phenomena in the fields of flotation, lubricants, fillers and pigments, dispersion of solid bodies, mech. treatment of metals, etc., are discussed. W. R. Henn

The scientific and technical significance of aerosols. Friedrich Müller. *Kolloid-Z.* **90**, 1–10(1940).—A brief review of the field of aerosols with special reference to the progress made in recent years, and confined chiefly to methods of dispersion, properties and methods of investigation. There are 131 references. A. L. Kibler

Gelatinated (foamy) emulsions. III. Effect of aliphatic monatomic alcohols on the emulsion-forming properties of sodium oleate. L. Ya. Kremnev and Yu. G. Khazina. *Trudy LKKhTI (Lab. Kolloïdnoï Khim.)* **1939**, No. 7, 93–102; *Khim. Referat. Zhur.* **2**, No. 5, 17(1039); cf. *C. A.* **30**, 2075[8].—Ethyl, Pr, amyl, octyl and cetyl alcs. were added in different amts. to solns. of Na oleate which was used to emulsify benzene. An addn. of alc. in small concns. increased the amts. of emulsified benzene, but the emulsifying ability of benzene decreased with an increase in the concn. of alc. The increase in the emulsifying ability of alc. is explained by the increase in the degree of dispersion of the emulsifier, by the suppression of its hydrolysis and by the increase in the hydrophobic properties of the components of the soap soln. The decrease in the emulsifying ability at large concns. of the alcs. in any phase (as shown by measuring the surface tension and the mech. stability of the adsorption layers) is caused by the expulsion of Na oleate by the alcs. from the interface surface, thus lowering the stability of the adsorption layers. W. R. Henn

The electrical double layer. General introduction. Eric K. Rideal. *Trans. Faraday Soc.* **36**, 1–4(1940).—The two general views of the origin and structure of the elec. double layer in colloidal systems are discussed: one based upon adsorption phenomena, and the other regarding the colloidal particle, an ionogenic one, as a large multivalent ion, the surface ionic linkages completely dissocg. in the soln. Data are desirable for interphases in non-aq. media. Victor R. Deitz

Use of thin layers in electrophoretic separation. J. St. L. Philpot. *Trans. Faraday Soc.* **36**, 38–46(1940).—A large-scale electrophoretic separator is described in which the substance to be sepd. flows in a thin layer between layers of dil. electrolyte. The conditions for successful sepn. are discussed. C electrodes in 5 *M* NH_4Br can carry 6 amps. without gassing. It is concluded that in some favorable cases the app. has its advantages, whereas in unfavorable cases difficulties arise to interfere with practical applications. Victor R. Deitz

Properties of detergent solutions. IX. Electrophoretic mobility of oil drops in detergent solutions. J. Powney and L. J. Wood. *Trans. Faraday Soc.* **36**, 57–63(1940); cf. *C. A.* **32**, 5279[1].—Detns. of the electrophoretic mobility of highly refined mineral oil (Nujol) dispersed in cond. water are described. A value of 4.35 μ/sec./cm. at 25° was obtained as the mean of 900 detns. on 6 different Nujol dispersions. The effect of alkalies on the mobilities are plotted for the pH range 8–12. The mobilities of oil drops in the presence of Na dodecyl sulfate, dodecyl

pyridinium chloride, Na laurate and Na oleate were detd. over a range of concns. and the results correlated with the constitution of colloidal electrolyte solns.
Victor R. Deitz

Electrokinetics. XXIII. Electrokinetics as a tool for the study of the molecular structure of organic compounds. Ross Aiken Gortner. *Trans. Faraday Soc.* **36**, 63–8(1940); cf. *C. A.* **33**, 6114[9].—Previous studies are reviewed on homologous series of the aliphatic alcs., aliphatic acids, Et esters of the aliphatic acids, the acetates of the aliphatic alcs. and a series of the derivs. of benzene; most of the compds. have been studied at both a cellulose-org. liquid and an Al_2O_3-org. liquid interface (cf. *C. A.* **32**, 6127[6]; **33**, 6114[9]). The technique consists in detg. the streaming potential with an app. in which the solid to be studied is packed in the central portion of the cell and the org. liquid is then streamed through the diaphragm from one reservoir to the other under a known and controlled hydrostatic pressure. A quadrant electrometer is used as a null instrument.
Victor R. Deitz

Streaming potentials and surface conductance. A. J. Rutgers. *Trans. Faraday Soc.* **36**, 69–80(1940); cf. *C. A.* **33**, 1194[4], 3230[4].—The anomalous behavior of the electrokinetic potential *vs.* concn. graph for solns. of KCl (0 to 80 × 10^{-6} mol./l.) is attributed to surface conductance. Data with a new app. are given for solns. of KCl (0–400 × 10^{-6} mol./l.), HCl (0–200 × 10^{-6} mol./l.), $CaCl_2$ (0–100 × 10^{-6} mol./l.) and of $Al(NO_3)_3$ (0–0.30 × 10^{-6} mol./l.). It is concluded that forces other than purely electrostatic ones must play the main role in the neighborhood of the wall, since great nos. of pos. and neg. ions are found in that region.
Victor R. Deitz

Examination of electrokinetic charge density as a function of the thickness of the double layer. A. J. Ham and E. D. M. Dean. *Trans. Faraday Soc.* **36**, 52–7(1940).—The electrophoretic mobility was measured macroscopically by the moving-boundary method on dispersions of octadecane in salt solns. at 25° and at pH 5. The mobilities and potentials decrease regularly and tend to limiting values, depending on the particular cation added; the charge density, as calcd. on the basis of the theory of Gouy (*C. A.* **4**, 2231), rises throughout in the cases of NaCl and $BaCl_2$ and irregularly in the case of $LaCl_3$. Both electrophoretic charge d. and potential fall as higher-valency cations are added to a 0.01 *M* NaCl soln., the latter having already fixed the thickness of the double layer. The possible limitations of the Gouy theory are discussed.
Victor R. Deitz

Ionic concentrations at interfaces. G. S. Hartley and J. W. Roe. *Trans. Faraday Soc.* **36**, 101–9(1940).—The zeta-potential is considered determinant of the local ionic concns. near the surface of a particle owing to consequent alterations in the apparent dissocn. consts. The problem is treated theoretically and some applications are discussed. As an example of an acid-base equil. present in the system almost entirely adsorbed at an interphase, the case of an aq. paraffin-chain (cetane sulfonate and cetylpyridinium) salt soln. is investigated. Diphenylazo-*o*-nitrophenol (I) was used as the indicator for the pH range studied, 6 to 8.5. Measurements were made by means of light absorption by use of a photoelec. photometer calibrated by standard solns. The bulk H^+ concn. was measured similarly with a "nonadsorbed" indicator in place of the amphipathic one, viz., *p*-nitrophenol. The limitations of the measurements are discussed.
Victor R. Deitz

Graph for the determination of the size distribution of pulverized materials. A. Giannone. *Atti X° congr. intern. chim.* **4**, 650–6(1939)(in Italian).—G. advocates the use of a graph based on a series of Wagner turbidometer results, which permits the detn. of the frequency of a particle of a size below a certain value in each sieve fraction. This graph extends and generalizes that of Haegerman (*C. A.* **30**, 4291[2]).
Henri Marc

Surface migration of ions and contact exchange. H. Jenny and R. Overstreet. *J. Phys. Chem.* **43**, 1185–96 (1939); cf. *C. A.* **30**, 4739[4].—A theory of ionic migration on surfaces and contact exchange of ions in colloidal systems through the medium of overlapping ionic "oscillation volumes" is advanced. Expts. on the migration of ferrous ions in gels and sols of bentonite clays are explained by use of the theory. It suggests a new mode of mineral nutrition of plants with interpenetrating root and soil colloids. Such roots are shown to gain as well as lose nutrient cations.
H. E. Phipps

Constitution of the alleged "thiessen hydrates." Harry B. Weiser, W. O. Milligan and W. J. Coppoc. *J. Phys. Chem.* **43**, 1109–20(1939); cf. *C. A.* **29**, 2816[3].—Dehydration isotherms were made for the hydrous gels prepd. by slow hydrolysis at 15° of ferric, stannic and silicon ethylates. But one point of inflection was found and that one (hydrous silica) varied. The gels of Fe and Sn were oxides with adsorbed or entrained water. There was no indication of the existence of the series of "thiessen hydrates."
H. E. Phipps

Some inorganic gels prepared by the trituration of hydrated solid salts. Tominosuke Katsurai and Masao Huda. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 458–62(1939).—Gels of various hydroxides were obtained by triturating hydrated solid salts with globules of NaOH. The materials used were: (*a*) $MnSO_4.5H_2O$; $MnSO_4$:NaOH = 1:4 (molar ratio). A viscous gel is formed. (b) $FeCl_3.6H_2O$; $FeCl_3$:NaOH = 1:6. A sand-like ppt. is formed. The gel does not dissolve in H_2O. (c) $FeSO_4.7H_2O$ and $FeCl_3.6H_2O$; $FeSO_4$:$FeCl_3$:NaOH = 1.2:12. The gel does not dissolve in H_2O. The ppt. is distinctly attracted by an ordinary horse-shoe magnet. (d) $CoSO_4.7H_2O$; $CoSO_4$:NaOH = 1:4. (e) $NiSO_4.7H_2O$; $NiSO_4$:NaOH = 1:4. A very viscous gel is formed. (f) $CuSO_4.5H_2O$; $CuSO_4$:NaOH = 1:4. A very viscous gel is formed. The ratios of the respective sedimentation vols. of the ppt. prepd. in the wet way and by trituration are in their respective order 2.9, 5.7, 2.9, 1.7, 5.5, 6.9.
R. S.

Analysis of curves of birefringence due to shape. A. Frey-Wyssling. *Kolloid-Z.* **90**, 33–40(1940).—The curves of birefringence (n_3^2-n_2^2 *vs.* n_2^2, with n_a,n_b, n_2 refractive indexes of the mixt. and of the imbibing fluid, resp.) in Wiener's theory [*Abh. Sächs. Ges. Wiss.* (*Math. Phys. Kl.*) **32**, 507(1912)] are hyperbolas. Their axes are strongly inclined with respect to the resp. coördinate system. For systems contg. rod-like particles the angle ϑ between the *y*-axis and the axis of the hyperbola varies between 45° and 40° 07′ if the relative vol. δ_1 of the one component decreases from unity to zero. In the case of particles of laminar form ϑ is neg. and varies from −45° to −22°30′ with $1 \geqq \delta_1 \geqq 0$. The exptly. detd. curves do not show any obvious inclination of the hyperbolic axis. This fact is due to the geom. transformation given by the hundredfold heightening of the scale in plotting the values of the double refraction. Inclinations occurring in these cases indicate deviations from Wiener's theory. F.-W. undertakes to correlate these deviations with the polarity of the constituents and of the imbibing liquid. Homopolar substances combined with homopolar liquids should give values in agreement with the theory. In a mixt. of heteropolar materials the exptl. degree of birefringence seems to be lower than the theoretical one, whereas in a mixt. of components of different polarity the exptl. value is found to be greater.
Robert Simha

Solvation of compounds of high molecular weight. Z. A. Rogovin. *Uspekhi Khim.* **8**, 687–703(1939).—Review. 58 references. **Properties of cellulose esters.** *Ibid.* 704–18.—Review and theoretical, especially of R.'s own works. 39 references.
F. H. Rathmann

Anisotropy of cellulose sheet. D. G. Drummond. *Nature* **145**, 67(1940).—Cellophane sheet is birefringent in a way that might be expected from an extrapolation of Spence's results (*C. A.* **33**, 9073[9]) for sheets made from cellulose esters. The relative unimportance of side-chain orientation in cellulose itself results in a generally greater birefringence and a change in the "slow-ray direction" from 90° to the direction of extrusion usually found by Spence for ester films to values of 43–72°. θ, n_α, β, γ and $n_{\alpha-\gamma}$ are tabulated for the acid- and water-washed sheet, wetted and air-dry, and for sheets undried during manuf., wet, dried free, and dried stretched.
G. M. Petty

Contributions to the knowledge of the mechanism of deformation of cellulose hydrate. VI. (2). Viscosity determinations on stretched and unstretched filaments. J. de Booys, H. L. Brédee and P. H. Hermans. *Rec. trav. chim.* 59, 73–6(1940); cf. *C. A.* 33, 2701⁹.—Detns. in two different solvents show the same viscosity for solns. of unstretched and stretched cellulose filaments. Since a drop in viscosity would be expected for the stretched filaments had the energy of stretching to rupture been used to break primary valency bonds, it is concluded that in the process of stretching cellulose filaments no mol. chains are broken to any appreciable extent. John E. Vance

The mechanism of water adsorption in gelatin gel. A. Weidinger and H. Pelser. *Rec. trav. chim.* 59, 64–72 (1940).—The different colors of gelatin gels contg. $CoCl_2$ were observed. The colors are typical of different amts. of adsorbed water and allow a distinction to be made between bound (intramicellar) and free (intermicellar) water. X-ray spectrograms showing the magnitude of the side-chain spacing gave a sep. measure of the intramicellar water. The conclusions are that bound water is to be thought of as intramicellar water, free water as intermicellar. In the course of water adsorption the micelles first become filled with water, the intermicellar water adsorption beginning only after satn. of the micelles has been completed. Small amts. of $CoCl_2$ do not interfere with intramicellar adsorption of water, but with high salt content the salt seems to intrude into the micelles. John E. Vance

Liesegang's diffusion histology. K. Zeiger. *Kolloid-Z.* 89, 115–23(1939).—Discussion of L's. contributions to colloid chemistry with a list of his publications. F. S.

Studies of sulfonates. VI. Effect of sodium chloride on the solubility of sodium dodecyl sulfonate and sodium tetradecyl sulfonate. The solubility at 50° of calcium dodecyl sulfonate and calcium dodecyl sulfate in aqueous solution of the corresponding sodium salts. H. V. Tartar and Richard D. Cadle. *J. Phys. Chem.* 43, 1173–9(1939); cf. *C. A.* 33, 8084⁴.—NaCl decreases the soly. of the Na salts and also increases the temp. and decreases the concn. at which micelles begin to form. The soly. of Ca dodecyl sulfonate and dodecyl sulfate in solns. of the corresponding Na salts was detd. The reversal of the soly. curve of the former is attributed to the formation of the complex ionic micelles with both Ca and Na "gegen ions." The Ca laurate soly. was too small to be detd. H. E. Phipps

An empirical relation between solubility of slightly soluble electrolytes and dielectric constant of the solvent. J. E. Ricci and T. W. Davis. *J. Am. Chem. Soc.* 62, 407–13(1940).—Soly. data of a no. of salts indicate that the activity coeff. of a salt in satd. soln. is, in many cases, practically const. and independent of the dielec. const. This observation leads to an empirical relation between the soly. of a slightly sol. electrolyte and the dielec. const. of the solvent which makes it possible to predict the soly. of a salt in other media from the soly. in H_2O without knowledge of ionic diams.; this relation is $\log S_2 = \log (2K^2/\nu z_+z_-) + \log D_2 + \log T - \frac{2}{3}\log [(1.8123 \times 10^6 z_+z_-/DT) - 50.288\ Ka]$, where K is the neg. log. of the activity coeff. in the first medium. Calcd. and observed solubilities (cf. *C. A.* 34, 925⁹) are compared. The agreement is, in general, satisfactory, at least as to the order of magnitude, and is as good as that obtained by the Born equation where ionic diams. are estd. A. B. G.

Hygroscopicity of mixtures. N. Schoorl. *Pharm. Weekblad* 76, 1541–3(1939).—The vapor pressure of a soln. contg. 2 solutes is lower than the pressure of separate solns. of the solutes. Therefore the hygroscopicity of the mixt. is greater than that of either of the components taken separately. Felix Saunders

The partial pressure of ammonia, carbon dioxide and water over copper ammonium solutions. N. M. Zhavoronkov. *J. Chem. Ind.* (U. S. S. R.) 16, No. 10, 36–7(1939).—Partial pressures are detd. from 20 to 80° over solns. of Cu NH_4 formate. Satn. of the solns. with CO at lower temps. has almost no effect on the partial pressures. At the higher temps., the total pressure is almost unchanged, but the partial pressure of NH_3 is lower and that of CO_2 is higher than over solns. contg. no CO. Calcn. of the differential heat of soln. gives the following values: for NH_3, 8980 cal./mole in solns. contg. 125–75 g./l., for CO_2, 15,000 cal./mole in solns. contg. 58.5–85 g./l. and for H_2O, 11,900 cal./mole in solns. contg. 730–803 g./l. H. M. Leicester

Kinetic interpretation of osmotic pressure. W. V. Metcalf. *Kolloid-Z.* 90, 11–16(1940).—The usual theories of osmotic pressure are criticized. A pressure-equil. theory is proposed. Its main features are as follows: The force that makes the liquid rise in the tube is the diffusion pressure of the solute which together with the excess diffusion pressure of the solvent acts on the side of the membrane where the pure solvent is found. The force that makes the solvent pass through the membrane into the soln. is given by the excess of the diffusion pressure of the solvent on the side of the pure solvent. This excess is caused by the diffusion of the solute in the soln. The pressure acting on the membrane is the diffusion pressure of the solute. This pressure maintains the hydrostatic excess pressure on the side of the soln. because the increased diffusion pressure of the solvent on the other side ceases to exist as soon as equil. is reached. This theory should furnish a satisfying interpretation of related phenomena such as the lowering of vapor pressure and the lowering of the f. p. Robert Simha

Effects of certain salt mixtures on the dissociation of glycine and alanine. A. C. Batchelder and Carl L. A. Schmidt. *J. Phys. Chem.* 43, 1121–32(1939); cf. Simms, *C. A.* 23, 5388.—Some of Simms' expts. on the effect of mixtures of $CaCl_2$, $MgCl_2$ and NaCl on the pH of glycine solns. were repeated but his results were not verified. Theoretical and exptl. investigations were made on the effect of salt mixts. of $MgCl_2$, $CaCl_2$, $BaCl_2$ and NaCl on the ionization of alanine in both acidic and alk. solns. H. E. Phipps

Outline of an activity theory of nonelectrolytes. I. A. Musil. *Österr. Chem.-Ztg.* 42, 371–81(1939); cf. *C. A.* 31, 8288⁹.—The Margules integrated form of the Duhem-Margules differential equation is related through the definition of activity to the changes in partial molal heat content and entropy which occur on mixing liquids to form non-electrolytic solns. For a binary mixt. the equation derived for the activity of component 1 is $\ln (a_1/N_1) = (\Delta\bar{H}_1 - T\Delta\bar{S}_1)/RT - \ln N_1 = \alpha_2 N_2^2/2 + \alpha_2 N_2^2/3$ in which a is activity, $\bar{H}$ and $\bar{S}$ are partial molal heat content and entropy, N_1 and N_2 are the mole fractions of components 1 and 2, and α_2 and α_3 are the Margules interaction consts. A similar equation holds for component 2. The data and method of Zawidski (*C. A.* 4, 702) are used to obtain numerical values of the Margules consts. for 12 pairs of liquids. About 60 references. **II. Energy of interaction and entropy of mixing.** *Ibid.* 395–406.—The causes and relations of forces between mols. in binary mixts. are discussed. An attempt is made to survey and improve the theory of solns. of nonelectrolytes, with due recognition of the contributions of others. The treatment is partly theoretical and partly empirical and leads to the calcn. of activities, partial molal heat contents, free energies and entropies of mixing, differential heats of soln. and diln. and partial sp. heats of the components. E. R. Smith

The application of electromotive-force measurements to binary metal systems. Harry Seltz. *Trans. Electrochem. Soc.* 77, 25 pp.(preprint)(1940).—E. m. f. studies of aq. electrolytes have contributed to some of the most important advances in the understanding of the nature of such solns. Today in the Debye-Hückel theory there is a better theoretical basis for the treatment of electrolytes than for any other type of soln. On the other hand, binary liquid metal solns., which at first sight might be thought to be relatively simple in nature, have received little attention. The thermodynamic properties of only a few such systems have been investigated previously. The thermodynamic properties of the soln. can be evaluated from the e. m. f. measurements. These thermodynamic data are then applied to the calcn. of phase equil. and to the calcn. of the entropies, free energies and heats of formation of any intermetallic compds. that may occur. C. G. F.

Electrochemistry of simple interphases, with special reference to that between mercury and solutions of electrolytes. S. R. Craxford. *Trans. Faraday Soc.* **36**, 85–101(1940).—A theoretical discussion is presented (1) for the completely non-polarizable interphase whose potential is independent of the amt. of charge flowing across it, and (2) for the completely polarizable interphase which behaves as if it contained a boundary that no charged particle can cross. Exptl. data for case (2) are given for the interface between Hg and a soln. contg. no mercurous ions over the potential range $E_{N.Cal.} = 0.0$ to -1.3 volt, viz.: KNO_3, NaCl, KI and $CaBr_2$ from M to 0.001 M. The capacity of the interface for all pos. ions is the same, namely, 19 microfarads/sq. cm. The capacity for anions varies, being larger for the more deformable ion: SO_4^{--}, 40.3 mF./sq. cm.; NO_3^-, 24; ClO_4^-, 26; Cl^-, 43; CNS^-, 53; Br^-, 93; I^-, 157. V. R. D. 1

The contact difference of potential between barium and zinc. The external work function of zinc. Paul A. Anderson. *Phys. Rev.* **57**, 122–7(1940).—The methods of contact-potential measurements (cf. A., *Ibid.* **49**, 320 (1936); *C. A.* **29**, 7173[4]; **33**, 1207[1]) are extended to Zn, using the retarding potential method with variable anode, in tubes sealed from the pumps and gettered with vaporized Ba. Observations made on three tubes and 15 pairs of Ba-Zn surfaces gave a mean value of 1.76 v. for the contact p. d., reproducible and const. to ±0.02 v., which gave a value of 4.28 ± 0.02 for the work function of pure Zn at room temp. Frank Gonet 2

Oxidation-reduction potentials and their applications. A review. Samuel Glasstone. *Trans. Electrochem. Soc.* **77**, 13 pp.(preprint)(1940).—A brief review is presented of the various directions in which oxidation-reduction potential measurements have been applied in recent years by the chemist and the biologist. Among the applications discussed are potentiometric titrations, indicator action, indicators for biol. reactions, and irreversible potentials. C. G. F. 3

Preparation of metallic magnesium with calcium carbide as reducing agent. I. Thermodynamical investigation on the reactions between MgO and CaC_2. Ryosaku Matuura, Masao Utino and Hidcaki Tuda. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 294(1939).—As predicted from thermodynamic calcns., powd. lightly calcined magnesite and com. CaC_2 when heated at 1200° under 1–2 mm. pressure in an iron tube react quantitatively according to $MgO + CaC_2 = Mg + CaO + 2C$. **II. The conditions for the reaction $MgO + CaC_2 = Mg + CaO + 2C$.** *Ibid.* —From results obtained at 1100°, 1200° and 1300°, the highest yields of Mg were obtained with (1) pressures maintained below 10 and preferably below 1–2 mm., (2) equiv. proportions of reactants, (3) use of magnesite burned at 700° and (4) use of finely powd. materials. **III. The influences of impurities and fluxes on the reaction $MgO + CaC_2 = Mg + CaO + 2C$.** *Ibid.* 294–5.—Impurities such as CaO, C and $MgCO_3$ have practically no effect on the reaction; SiO_2, Fe_2O_3 and Al_2O_3 react with CaC_2 but the products are not volatilized with the Mg. Of CaF_2, $CaCl_2$, NaCl, $AlF_3.3NaF$, Fe_2S_3, CuS, CoS and $Ca(BO_2)_2$, only CaF_2 accelerated the reaction. G. A. 4

Thermal polymerization of styrene and its inhibition. Stanley G. Foord. *J. Chem. Soc.* **1940**, 48–56; cf. *C. A.* **33**, 3629[9], 7932[8].—The kinetics of the polymerization of $PhCH:CH_2$ (I) at 60, 90 and 120° were calcd. from expts. with various inhibitors and retarders. The degree of polymerization at any time t was measured in sealed, evacuated viscometers. The relative viscosity, n_r, for a concn., C, was measured with pure I equal to unity, and rates were derived from the relation $\log n_r = kC$, where the const. k is proportional to the mol. wt. of a given polymer. The curves $\log n_r$-time are of the same form as the time-concn. curves. A conversion factor to derive the latter was obtained by a single measurement of the degree of polymerization by the independent method of the pptn. of the polymer from C_6H_6 with EtOH. Classified on the basis of inhibition or retardation of the polymerization, 130 org. substances fall into 4 groups, 50% of which lie in 2 groups of chief interest. An "inhibitor" is defined as having the property of causing a more or less protracted induction period, whereas a "retarder" reduces the rate of the subsequent reaction. Effective groups for stabilization are quinoid, nitro, phenolic hydroxy, amino and nitroso. The data for the representative inhibitor, quinone, for 90 and 120° were used to calc. max. polymerization rates and the energy of activation (28,000). The mechanism that was assumed required each mol. of inhibitor to deactivate n mols. of I. It is possible to calc. n and nM, the mean mol. wt. of the polymer, from the data of various inhibitors. The mechanism is consistent with the fact that the several inhibitors give approx. the same values of n and nM. On this basis the nM for the 120° polymer ranges from 20,540 to 24,800. N. T. Farinacci 5

Kinetics of the reaction between potassium persulfate and the alkyl iodides. I. Influence of solvents, acids and salts. M. S. Telang and V. V. Nadkarny. *J. Indian Chem. Soc.* **16**, 536–42(1939).—Detns. were made of the I formed in 2 hrs. at 50° from EtI-$K_2S_2O_8$ solns. in 10% aq. alc., 0.02 N in each reactant. Addns. of 5 vol. % of the lower aliphatic alcs., acids and esters had a strong effect, usually depressing, on the reaction rate; on ascending each homologous series, marked alternations in the effect were shown. Acids and salts, added in 0.8 N concn., catalyzed the reaction in the order: $HNO_3 > HCl > H_2SO_4 > Fe(NO_3)_3 > KCl > NH_4Cl > NaCl > CuSO_4 > H_3PO_4 > NaNO_3$, K_2SO_4, Na_2SO_4. HNO_3 does not oxidize EtI under these conditions. A. O. Allen 6

Concerning reactions of the type $A_{solid} + B_{gas} \rightarrow C_{solid}$ and the kinetics of the neutralization of solid benzoic acid by gaseous ammonia. Dora Markowska and Gabriel Valensi. *Bull. soc. chim.* **6**, 1522–41(1939).—At a given temp. and pressure, the fraction m of benzoic acid reacting in t minutes is given by the equation $F(m) = (4.167 + m)\log(1 + 0.24\,m) + (1 - m)\log(1 - m) = Kt/d_0^2$ in which d_0 is the most probable diam. in cm. of the needle-shaped crystal. At 760 mm. the values of K ($\times 10^{-6}$) for several temps. are: 0°, 2.1; 22.5°, 3.7; 30°, 6.5; 40°, 6.5; 50°, 2.5. For 25° K varies according to the expression $K = 3.7 \times 10^{-6}\,p^{0.5}$ where p is expressed in atms. The complex nature of the variation of reaction rate with temp. is discussed. A. A. Vernon 7

The electrostatic influence of substituents on reaction rates. I. F. H. Westheimer and Martin W. Shookhoff. *J. Am. Chem. Soc.* **62**, 269–75(1940).—The electrostatic theory was applied to the problem of the effect of polar substituents on reaction velocities (cf. *C. A.* **29**, 7763[8]). The rates of alk. hydrolysis of the following pairs of compds. were measured by an elec. cond. method: oxamide and Na oxamate, *tert*-BuOAc and *tert*-Bu chloroacetate, the *tert*-Bu ester of dimethylglycine and the chloride of the *tert*-Bu ester of betaine. It is shown, by equations of Kirkwood and Westheimer (cf. *C. A.* **32**, 8244[8]), that the ratio of the rates for each pair is quantitatively in accord with the hypothesis that the effect of a polar substituent on the velocity of the hydrolyses is primarily electrostatic in origin. A. B. Garrett 8

Kinetics of the reaction between ethylene glycol and lead tetraacetate. R. P. Bell, J. G. R. Sturrock and R. L. St. D. Whitehead. *J. Chem. Soc.* **1940**, 82–4.—$(CH_2OH)_2$ was treated with $Pb(OAc)_4$ in HOAc at temps. between 18 and 45°. The rates were followed by adding measured samples to KI soln. and titrating the liberated I. The reaction was found to be first order with respect to each reactant and the energy of activation was calcd. as 20,900 with a probable error of 1000 cals. In the reaction the steric factor in $k = PZ\,e^{-E/RT}$ is approx. unity. A reaction between 2 uncharged mols. with such a high steric factor suggests a mechanism involving free radicals rather than ions (cf. Waters, *C. A.* **34**, 1000[3]). N. T. F. 9

Kinetics of the thermal decomposition of fully deuterated diethyl ether. J. G. Davoud and C. N. Hinshelwood. *Proc. Roy. Soc.* (London) **A174**, 50–6(1940); cf. *C. A.* **33**, 6126[9].—The kinetics of the decompn. of $(C_2D_5)_2O$ was studied in detail. It was found that the presence of increasingly small quantities of NO caused the rate of decompn. of ether to fall to a well-defined limit because of its suppression of reaction chains. The ratio of $\rho_0(p)$/

$\rho_0(D)$ was found to have a mean value of 2.14 while the ratio of $\rho_\infty(H)/\rho_\infty(D)$ had a value of only 1.78, where ρ_0 is the normal rate of decompn. and ρ_∞ of the fully inhibited reaction (using a NO inhibitor). The apparent chain length (ratio of ρ_0/ρ_∞) was found to be 3.7 and 3.0 for the light and heavy ether, resp. One of the chain steps involves a complete rupture of a C–H or C–D bond. Activation energies (E) were calcd. and show that there is little change in E with initial pressure of ether and that the value of E for the D compd. is several thousand cals. greater than that for the H compd., which is believed to mean that the decompn. probability of the activated D compd. is somewhat greater than that of the H compd. The effect of D on ordinary ether at low pressures (520–5°) was investigated with the conclusion that D increases the rate of reaction, which seems to point to an unknown factor influencing the energy exchange. Frank Gonet

Organic-reaction catalysts. Recent developments. L. Light. *Chem. Products* **3**, 29(1940).—A review covering the use of BF_3, colloidal Rh, Ni and Ni alloys, Pd, etc. 9 references. Leopold Schefian

Catalytic isotopic exchange of gaseous oxygen. V. Sorption of oxygen by manganese oxide and the exchange reaction of oxygen atom between oxygen gas and manganese oxide. I. Sorption experiment. Noriyosi Morita. *Bull. Chem. Soc. Japan* **14**, 520–9(1939); cf. *C. A.* **33**, 4500[8].—Adsorption of O was studied with Mn oxide at various temps. and const. pressure of 2/3 atm. From room temp. up to 275°, adsorption is very slight but a sudden increase in rate is noted at 325° which is about 15 times greater than at 275°. This increase continues up to 530° but after that temp., desorption occurs. If oxide which has lost O above 530° is cooled to a lower temp. it will again adsorb. G. M. Murphy

Catalyst for producing acetic acid from acetaldehyde. Tadahumi Yano. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 297–8(1939); cf. following abstr.—When air was passed at the rate of 3 l./hr. through mixts. of 5 cc. AcH soln. (sp. gr. 0.837 at 12°), 30 g. of 89.9% HOAc and 0.5 g. of $CoSO_4.7H_2O$, $K_2Cr_2O_7$, $KMnO_4$, K_2CrO_4, $Fe_2(SO_4)_3$, $Cu(OAc)_2$ or MnO_2, resp., the yields of AcOH from the AcH present were (% yield, l. air passed through the soln.): 56.6, 8.0; 21.6, 8.5; 15.6, 5.5; 9.6, 4.5; 1.6, 3.0; 0, 3.0; and 0, 3.0. MnO_2 is a catalyst only when the H_2O content of the mixt. is low. Based on expts. made at 25–60° in the presence of MnO_2, air is most effective at 30° in converting AcH to AcOH in AcOH soln. (best results with 5–10% soln. of AcH in AcOH). With $CoSO_4.7H_2O$ as the catalyst, best results were obtained at 40°. The catalytic effect of $CoSO_4.7H_2O$ is not decreased by the presence of H_2O. George Ayers

Catalyst for producing acetaldehyde from acetylene. Tadahumi Yano. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 299–300(1939); cf. preceding abstr.—For the formation of AcH by passage of C_2H_2 into 25% H_2SO_4 contg. 1 g. HgO catalyst at 55°, practically the same results were obtained when metallic Hg and MnO_2 were substituted for the HgO. When C_2H_2 was passed at 55° through 300 cc. of catalyst contg. 2 g. Hg, 50 g. of 66°Bé. H_2SO_4 and 6 g. MnO_2, 191.3 l. was absorbed and 283 g. AcH obtained (yield, approx. 78.45%). Based on expts. at 55–65°, the life of the catalyst is shortened at the higher temps. An increase in the concn. of the H_2SO_4 or addn. of $Fe_2(SO_4)_3$, $Fe(OAc)_3$ or MnO_2 has little effect on the yield of AcH, but the life of the catalyst is prolonged. Agitation of the acid soln. increases the rate of reaction. G. A.

Hydrogenation of a higher ketone with catalysts consisting mainly of copper, cobalt and cerium under atmospheric pressure. Kiitiro Kino and Syunziro Kato. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 362(1939).—A higher ketone, prepd. from com. stearic acid and having a m. p. of 75.5–78° and zero hydroxyl value, was hydrogenated best at 150° during 8 hrs. by Cu-Co, Co-Ni and Ni-Ca(OH)$_2$ catalysts to yield the secondary alc. Cu, Cu-Zn, Cu-Ag, Cu-Cr, Cu-Ce, Cu-Ba, Co, Ce and Ni-KOH were unsuitable as catalysts. George Ayers

The preparation of a higher secondary alcohol from a higher ketone by hydrogenation under pressures of five and twenty atmospheres. Kiitiro Kino and Syunziro Kato. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 363 (1939); cf. preceding abstract.—The higher ketone prepd. from com. stearic acid, when hydrogenated under 5 atm. pressure in the presence of Co-Ni catalyst, gave a practically quant. yield of the secondary alc., the product having a hydroxyl value of 101.3 (hydroxyl value of the product formed by reducing the ketone with Na and BuOH was 104.5). Under the same conditions, with Cu-Co and Ni-Ca catalysts the yields were good and the hydroxyl values of the products were 90.5 and 92.7, resp. Use of Cu-Zn, Co-Cu, Cu-Ce, Cu-Ba and Ni-Ca as catalysts resulted in products having rather low hydroxyl values. Hydrogenation of the ketone under 20 atm. pressure in the presence of Cu-Zn, Cu-Co, Cu-Ce, Cu-Ni, Co-Cu or Ni-Ca catalyst gave quant. yields of the secondary alc., the products having hydroxyl values between 100 and 103.7. George Ayers

The retardation of reactions and its connection with negative catalysis. Ch. Dufraisse and P. Chovin. *Rev. chim. ind.* (Paris) **48**, 258–64, 286–97(1939).—Discussion of various inhibition expts. that have been reported in the literature and a summary of the theories of antioxidants. Very complete literature references are given. A. A. V.

Pressure-volume-temperature relations for butane. W. B. Kay. *Ind. Eng. Chem.* **32**, 358–60(1940).—The vapor pressure of butane was detd. at a series of temps. from room temp. to the crit. point with various ratios of liquid vol. to vapor vol. In each case there was an increase in pressure with an increase in the value of the ratio amounting to 0.20–0.70 lb./sq. in. between the dew point and the b. p. at const. temp., indicating the presence of small traces of an impurity, probably isobutane. The exptl. data are plotted and a smooth curve drawn through the points. Temp. values at equal intervals of pressure are given in a table. Crit. temp. and pressure were found to be 306.0°F., and 550.1 lbs./sq. in., resp. By extrapolation of the mean d. line to the crit. temp., a value of 14.24 lbs./cu. ft. was obtained for the crit. d. In compressibility expts. 15 isotherms in both the high (1200 lbs./sq. in.) and the low (35 lbs./sq. in.) pressure regions, covering the temp. range from 100° to 536°F., were obtained for butane. These temp.-pressure data were plotted to give the isochors or curves of const. vol. from which the values of the pressure, vol., and temp. are taken and tabulated. The data are in excellent agreement with the data of Beattie, *et al.* (*C. A.* **33**, 1562[4]). E. J. M.

Liquid-vapor equilibrium relations in binary systems. The ethane–butane system. W. B. Kay. *Ind. Eng. Chem.* **32**, 353–7(1940).—Pressure-vol.-temp.-compn. (P-V-T-x) relations for the ethane–butane system at the liquid- and vapor-phase boundaries were detd. from the border curves of 5 different mixts. of known compn. and the vols. of their satd. liquid and vapor calcd. The mixts. contained 17.49, 45.10, 65.77, 82.18, and 94.72 mole % ethane, resp. The app. and exptl. technique were the same as those used in the ethane–heptane study (*C. A.* **32**, 4055[9]). The T-x diagrams of the coexisting liquid and vapor phases at const. pressure were constructed, and compared with those computed by means of the soln. laws. The results indicate definitely that the latter are inadequate for calcg. these relations at high pressures. The combination of the border curves of the mixts. and the vapor pressure curves of the pure constituents form a space diagram similar to that for the ethane–heptane and other binary systems studied. As compared to the ethane–heptane system the effect of compn. on the crit. consts. of the mixts. is not so marked. The temp.-d. curves of the satd. liquid and vapor of the 5 mixts. exhibit 2 points of inflection, barely noticeable for mixts. contg. small amts. of ethane, but quite apparent for mixts. rich in ethane. The exptl. data from several hundred equil. measurements and data for ethane and butane are plotted and summarized in a table. E. J. Mahler

Structure of the intermetallic phases in the systems W–Co and Mo–Co. III. M. M. Babich, E. N. Kislyakova and Ya. S. Umanskiĭ. *J. Phys.* (U. S. S. R.) **1**, 309–13 (1939).—See *C. A.* **33**, 7655[4]. E. H.

The systems Al–Pb–Cu and Al–Pb. W. Claus and Ingeborg Herrmann. *Metallwirtschaft* **18**, 957–60(1939).—In the ternary system, the fluid melts are found in the Pb-rich corner on the one hand and the Pb-poor Cu-Al melts on the other hand. The equil. diagram is shown. A series of frozen melts on the Al-Cu side of the ternary system shows that the miscibility gap experiences a widening at lower temps. on this side. In the Pb corner of the system, the melts exhibit analogous behavior. In the binary system Al–Pb, to det. the limits of the miscibility gap, alloys with 7, 3 and 2% Al were prepd. and examd. in the temp. range of 1200 to 1020°. With 7% Al, there is still layer formation at 1160 and 1020°. With 3% Al there is still layer formation at 1190 and 1020°. With 2% Al the alloy is in the zone of homogeneous soln. at 1200° but at 1020° there is marked layer formation. The shrinkage phenomena observed in the Al–Pb–Cu system are discussed. H. Stoertz

Note on the system SiO_2–CaO–H_2O. Vittorio Cirilli. *Ricerca sci.* **10**, 1042-3(1939).—Bessey (*Proc. of the Symposium on the Chemistry of Cements*, Stockholm, 1939) reported an isotherm of the system SiO_2–$Ca(OH)_2$–H_2O at 17°. In agreement with Bessey's results, C. found that at compns. CaO/SiO_2 between 2 and 1.5 in the ppt. the concn. in the equil. soln. has a value sufficiently close to that corresponding to the soly. of $Ca(OH)_2$ but nevertheless slightly lower, at the same temp. Bessey explains this behavior by assuming that there are two solid phases present in the ppt.: $2CaO.SiO_2.xH_2O$ and $3CaO.2SiO_2.xH_2O$. This interpretation disagrees with results of an x-ray investigation of the ppt. that can be sepd. from the equil. soln. As previously discussed (cf. *C. A.* **34**, 19[6]) it seems possible that in the range mentioned there are present $Ca(OH)_2$ and $3CaO.2SiO_2.xH_2O$. R. S.

The system trisodium phosphate-sodium carbonate–water. Kenneth A. Kobe and Alexander Leipper. *Ind. Eng. Chem.* **32**, 198–203(1940).—Study of the system Na_2O–P_2O_5–H_2O at 25° showed that the compn. of trisodium phosphate (I) varies with the compn. of the soln. from which it is crystd. Com. I corresponds approx. to $Na_3PO_4.{}^1/_7NaOH.12H_2O$. Its soly. in H_2O was detd. at 0, 25, 40, 60, 80 and 100°. The results disagree markedly with other detns. in the literature, probably because the salts used were of different compns. Soly. detns. in the system I–Na_2CO_3–H_2O at the above temps. showed that no double salts are formed and that Na_2CO_3 can be sepd. easily from I by crystn. Michael Fleischer

Determination of the thermodynamic scale of temperature below 1°K. by means of magnetic measurements. H. B. G. Casimir and W. J. de Haas. *Physica* **7**, 70–8(1940).—The errors involved in the method of de Haas and Wiersma (*C. A.* **30**, 5845[2]) for obtaining the thermodynamic scale of temp. below 1°K. are analyzed. These errors may be estd. from a rough detn. of adiabatic *M,H* curves. A few measurements on Fe NH_4 alum are discussed. John W. Knowlton

The radiation correction in calorimetry. F. E. Hoare. *Phil. Mag.* **29**, 52–65(1940).—The methods of using radiation corrections in calorimetry that were proposed by Regnault, Rowland, Dickinson and Nernst-Eucken are examd. The relative merits of the different methods are investigated generally. In each case the limits of error are considered. A mistake in sign is discovered in Rowland's original equations and it is shown that this has led to an erroneous graphic construction. The error has been repeated in the literature quoting Rowland. Formulas are derived for the error limits, expts. upon a cooling calorimeter being made also. The observed cooling measurements are treated by the various methods given above and the results compared. Calcns. are also made for the allowance for energy expenditure needed in realizing the initial and final parts of the curve in the Eucken-Nernst method. The radiation correction method proposed by Ferry is not considered as suitable for giving the true correction in the general case. S. Tolansky

Analytical calculations of thermodynamic properties. H. M. Robinson and Harding Bliss. *Ind. Eng. Chem.* **32**, 396–8(1940).—Equations for calcg. entropy, enthalpy, and energy changes in terms of vol. are derived for the Van der Waals, Wohl, and Beattie-Bridgeman equations of state. They were tested for entropy and enthalpy calcns. by comparisons with published values for propane, N_2 and CH_4, that were detd. graphically. The ranges of comparison included values near the crit. Except for occasional scattered points, the Beattie-Bridgeman equation was found satisfactory to 5–7% for entropy and 12% for enthalpy. The others were almost as good for entropy, but definitely worse for enthalpy. The advantage of the analytical method with vol. as the independent variable over the graphic method is discussed. H. W.

Total-heat entropy diagram for biphenyl. Sidney John Ellis. *J. Inst. Civil Eng.* **1938–39**, 227–40.—From the sp.-heat data of Findlay, the value of the entropy was integrated for the superheat region up to a total heat of 540 b. t. u. The efficiency of the biphenyl engine and a steam engine are compared between 400°–800°F. 3 graphs, 11 tables. Ann Nicholson Hird

Heat conductivity of rubber at low temperatures. Adolf Schallamach. *Nature* **145**, 67(1940).—The heat cond. of North British tire rubber, in cal./sec. cm. °K., is 0.00055 at 293°K., and 0.000010–0.000018 at 83°K., depending on the method used. Other specimens of rubber showed a comparable behavior. G. M. Petty

The new specific heats. Robert C. Heck. *Mech. Eng.* **62**, 9–12(1940).—Existing data on N, O, CO, H, CO_2 and H_2O are recalcd. by the use of engineering units. John W. Knowlton

Critical and coöperative phenomena. V. Specific heats of solids and liquids. A. F. Devonshire. *Proc. Roy. Soc.* (London) **A174**, 102–9(1940).—Theoretical. The sp. heats of simple substances in the liquid and solid phase were calcd. in terms of the intermol. forces, and were found in fair agreement with the experimentally detd. C_v values for Kr and A. The calcd. values were found to vary less rapidly with the temp., being too small at low temp. and too large at high temp. The calcd. coeff. of thermal expansion α and the cubic compressibility χ as functions of λ/kT are also given. Frank Gonet

Specific heat ratios for hydrocarbons. W. C. Edmister. *Ind. Eng. Chem.* **32**, 373–5(1940); cf. *C. A.* **32**, 3251[6].—The methods of the previous paper are extended to give $\gamma = C_p/C_v$ as a function of reduced temps. up to 2.5 and reduced pressures up to 1.2 for 17 hydrocarbons. The use of the correlation to calc. the power for adiabatic compression is discussed. Hood Worthington

The thermal capacity of pure iron. J. H. Awbery and Ezer Griffiths. *Proc. Roy. Soc.* (London) **A174**, 1–15(1940).—The sp. heat was detd. on a cylindrical specimen of Fe, weighing 1200 g., of purity higher than 99.99%, over the range 50–950°. The energy changes assocd. with the Curie point of Fe are not concd. closely around that point, but affect the sp.-heat curve over a wide range. In the range from 50° to the Curie point (755°) the sp. heat rises fairly regularly, except for a broad band centered around 200°, amounting to 2% at its max. Above the magnetic point, the sp. heat falls rapidly but the thermal effect of the magnetic transformation is still visible when the α-γ (body- to face-centered) transformation sets in. The transformation was found at least in part a true phase-change involving a latent heat, which was found to be 3.9 cal./g. This transformation is double, as the main peak occurs at 903°, but after the sp. heat fell to 0.37 cal./g., it rose again to a smaller but definite peak at 908° before falling to the value for γ-iron, which was found to be 0.14 cal./g. The app. is described in detail. F. G.

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

A. B. F. DUNCAN

The quantum-mechanical basis of statistical mechanics. Edwin C. Kemble. *Phys. Rev.* **56**, 1146–64(1939).—Theoretical and math. Bernard Lewis

Infrasonic and ultrasonic waves. Michel Adam. *Génie civil* **115**, 433–5(1939).—A discussion of their mech., phys., chem. and physiol. effects. A. N. Hird

Multiple scattering of electrons. S. Goudsmit and J. L. Saunderson. *Phys. Rev.* **57**, 24–9(1939); cf. *C. A.* **33**, 6135[1].—Theoretical, math. Bernard Lewis

The interaction potential in the scattering of protons by protons. A. S. Eddington and H. M. Thaxton. *Physica* **7**, 122–4(1940)(in English). W. F. Meggers

Scattering of mesons and the magnetic moments of proton and neutron. W. Heitler. *Nature* **145**, 29–30 (1940).—Math. A no. of theoretical difficulties, such as the diverging magnetic moment of the proton, and the large scattering cross sections for mesons, are due to an inadequate treatment of the spin and charge. "Higher proton states" with charges $2e$ and $-e$, and those with spin 3/2 might exist with a rest mass of 25–50 electron masses higher than that of the proton. The cross section for the scattering of mesons is then of the right order of magnitude and the magnetic moment of the proton diverges only logarithmically. G. M. Petty

Landau diamagnetism and the Fermi-Dirac energy distribution of the metallic electrons in graphite. K. S. Krishnan. *Nature* **145**, 31–2(1940).—The abnormal diamagnetism of graphite, which is confined to the direction of its hexagonal axis, conforms to the Landau diamagnetism of the Fermi free-electron gas contg. one electron per C atom and with a degeneracy temp. of about 520°K. 9
G. M. Petty

Does the mesotron obey Bose-Einstein or Fermi-Dirac statistics? P. L. Kapur. *Nature* **145**, 69(1940).—

Whether the mesotron obeys Bose-Einstein or Fermi-Dirac statistics depends on assumptions regarding the nature of the field, emission and absorption of which by the heavy particle is responsible for the interaction between elementary nuclear particles. Assuming a 2-particle field, so that a mesotron is always emitted or absorbed in conjunction with a neutrino or antineutrino, it is possible to explain the forces between the particles and to explain the phenomenon of β-disintegration. G. M. Petty

The photodisintegration of the deuteron in the meson theory. H. Fröhlich, W. Heitler and B. Kahn. *Proc. Roy. Soc.* (London) **A174**, 85–102(1940).—Math. A theoretical calcn. is given of the photoelec. effect of the deuteron on grounds of the meson theory of nuclear forces. Frank Gonet

The derivation of the quadratic equation for the masses of the proton and electron. Arthur S. Eddington. *Proc. Roy. Soc.* (London) **A174**, 16–41(1940).—Math. The derivation of the fundamental quadratic $10\,m^2 - 136\,m\,m_0 + m_0^2 = 0$ and the simplification of many phys. problems resulting from this are given in full. Frank Gonet

The masses of the neutron and mesotron. Arthur S. Eddington. *Proc. Roy. Soc.* (London) **A174**, 41–9 (1940).—Theoretical. E. concludes that the mesotrons have no connection with the so-called Yukawa particles, which are neutral spinless particles of mass $m_0 = 136\,m_e$. The elementary matter to be combined in the nucleus consists of protons (p), electrons (e), ordinary comparison (Yukawa) particles (c) and spin-comparison particles (s), which yield 4 possible kinds of bi-particles p_c, e_c, p_s, e_s. E. believes that owing to the large rest-energy (2.36 m_p) of the heavy mesotron p_s, the tendency will be to form p_c and e_s rather than p_s and e_c. Hence in its normal state the nucleus is taken to consist of protons and neutrons each with a comparison (Yukawa) particle (p_c, n_c). When a transition is about to occur the neutron is regarded as a combination of p_c and e_s. If the transition is spontaneous, the available energy is insufficient to provide for the emission of a mesotron e_s, and e_s is transformed into e_c before emission, by emitting an anti-neutrino, and the ordinary β-ray disintegration is obtained. If the transition is a consequence of the entry into the nucleus of a large quantity of energy, direct emission of e_s becomes possible and the 2nd transition $e_s \rightarrow e_c$ is deferred until the end of the natural lifetime of the mesotron in free space. Frank Gonet

The proton-deuteron transformation as a source of energy in dense stars. W. A. Wildhack. *Phys. Rev.* **57**, 81–6(1940).—Math. The rates of energy evolution due to the transformation to He ($H + H = D + e^+$ and $D + H = {}_2He^3 + \gamma$) in H, at d. of 10^4 to 10^8 g./cc. were calcd. on the basis of complete degeneracy (assuming a crystal-like spacing of the protons). The results indicate that any considerable quantity of H in white dwarf stars would lead to greater luminosities than those observed. W. concludes that the low effective mol. wt. (1.5) calcd. for some of these stars, using the white dwarf model, cannot be due to a high H content. This might be explained by a very large content (100%) of He^3, but is difficult to see how such great quantities could be present in these stars. The authors believe that this difficulty can be overcome by the revision of the observational data of the white-dwarf radii. Frank Gonet

The production of radioactive substances and neutron rays. Franz N. D. Kurie. *Am. J. Roentgenol. Radium Therapy* **43**, 107–12(1940).—An outline of the present concept of the structure of the atom is followed by a discussion of the fundamental principles of at. disintegration by particle bombardment, with several equations of typical disintegrations. The cyclotron is described in some detail. E. H. Quimby

Stable atomic nuclei and the present status of their classification. H. Jensen. *Naturwissenschaften* **27**, 793–803(1939).—A review dealing with requirements for nuclear stability, especially the application of Mattauch's rule, Harkins' rule, etc. The frequency of odd- and even-no. masses is discussed. The structure of nuclei with different Mattauch zones is used to systematize the possible structures. B. J. C. van der Hoeven

Recent progress in our knowledge of the structure and disintegration of atoms. A. Boutaric. *Génie civil* **115**, 383–6, 401–4(1939).—A review of nuclear chemistry. Ann Nicholson Hird

A simple rule for evaluating atomic constants. Po-Leon Woo. *Nature* **145**, 30–1(1940).—Math. Observed and calcd. values are compared for h, e, m_e, M_H, e/m and h/e. G. M. Petty

Electron liberation at the cathode of the glow discharge. Heinz Fischer. *Naturwissenschaften* **27**, 838–9(1939).—Recent work on electron liberation from the cathode as a function of cathode heating (Güntherschulze and Bär, *C. A.* **32**, 8911[7]) showed that $\gamma = i^-/i^+$ is of the order 0.1 to 1 and for const. total i = 0.5 ma. per sq. cm. γ increases linearly with the cathode drop. This work was repeated with H_2 in the range 0.2 to 2 or with glow discharge as well as with hollow-cathode discharge, c. d. from 1 to 10 ma. per sq. cm.; a brass cathode was used. The values found all lie on the same curve in agreement with previous work and γ is only a function of the cathode drop. B. J. C. van der Hoeven

A mechanical analogy to the motions of electrons in gases. G. D. Yarnold. *Phil. Mag.* **29**, 47–51(1940).—A simple demonstration model is described. S. Tolansky

The transition from glow to arc discharge. E. L. E. Wheatcroft and H. Barker. *Phil. Mag.* **29**, 1–15 (1940).—Cathode ray oscillographic observations are made upon the initial stages of the transition from the glow to the arc discharge. The abnormal glow for Cu electrodes in air at pressures of 0.2 to 1.2 mm. of Hg is studied. Direct evidence is obtained establishing the existence of intermittent voltage collapse. The transient breakdowns are initiated by a sudden drop in the interelectrode potential corresponding to a partial discharge of the self capacity of the electrodes. The previous history of the gas in the discharge tube affects the results obtained. The theory and origin of the observed effects are discussed. The thermal effects, field effects and cathodic bombardment influences are examd. It is not considered that the thermal or field theories can suffice to explain the observations. It is suggested that the ionic bombardment and resulting cathodic disintegration are the most promising avenues to be examd. for an explanation. S. Tolansky

The cause of multiple discharges in a Geiger-Müller counter. C. H. Collie and F. Morgan. *J. Sci. Instruments* **16**, 369-72(1939).—A demountable counter permitting controlled transition from simple to multiple type discharges was used to investigate the formation of double kicks. These were produced by the presence of small quantities of xylene vapor in the counter, the double kick being due to the release of an electron from the cathode when the xylene ions were discharged 10^{-3} sec. after the first discharge. Higher proportions of xylene gave rise to a larger and longer series of multiple discharges. M. McMahon

Emission of ionizing radiations by the salts of ordinary metals. Émile Thibaud. *Compt. rend.* **210**, 174–5 (1939); cf. *C. A.* **33**, 3254[5].—The state of the metal (Al, Mg, Cr, Mn and Sb were examd.), whether in thick or thin plates, or powder, or in various compds., e. g., oxide, sulfate, phosphate, sulfide, has no effect on the coeff. of absorption in air, or on the wave length of the radiations emitted. The phenomenon is therefore specific for the metal atom. C. A. Silberrad

A note on the Schottky effect. E. L. E. Wheatcroft. *Phil. Mag.* **29**, 16–17(1940).—The Schottky formula for the dependence of the total thermionic emission in the case of zero accelerating field is $\log I = \log I_0 + b\sqrt{V}$. According to Schottky this expression is derived by extrapolation from high fields, in which the acceleration is such that the distortions produced by space-charge effects are negligible. Gill (*C. A.* **32**, 3690[4]) considers the formula $I = I_0(1 + b\sqrt{V})$ to be better than that of Schottky.

An exptl. test is carried out in this paper in order to discriminate between the 2 suggested formulas. The results favor the expression proposed by Schottky.
S. Tolansky

Radius of the electron and calculation of photoelectric constant of metals. Theodore Ionescu. *Compt. rend.* 210, 170–2(1940); cf. *ibid.* 203, 537(1936), and Thomson, *C. A.* 33, 2793[8].—The radius of the electron, $\rho = h/2\pi mv$, where m is its mass and v its velocity, is verified by calcg. therefrom the photoelec. const. of Li, Na, K, Rb, Cs, Al, Cu, Ag and Au and comparing the results with those of expt. Fair to good agreement was obtained except for Au. C. A. Silberrad

Photoelectric effect in incandescent metals. V. Ricca and M. Della Corte. *Atti accad. Lincei, Classe sci. fis. mat. nat.* 29, 685–91(1939); *Nuovo cimento* 16, 410–16.—Math. The theory of Fowler (Du Bridge, *C. A.* 26, 2644; 27, 3663) concerning the photoelec. properties of metals is confirmed. At 2400°K. even radiation having wave lengths above 3600 A. produces a photoelec. effect on W, whose photoelec. "threshold" is at about 2660 A. A. W. Contieri

Examination of colored alkali halides for photoelectric Hall effect. Julian Evans. *Phys. Rev.* 57, 47–53(1939).—Five additively colored alkali halides were examd. for photoelec. Hall effect. From the upper limit assigned to the Hall effect it was computed that the mean free path of photoelectrons in rock salt is not much greater than the dimensions of a lattice cell. Bernard Lewis

Internuclear distances in Se_2, Te_2 and HgCl by electron diffraction. Louis R. Maxwell and V. M. Mosley. *Phys. Rev.* 57, 21–3(1939).—Electron-diffraction photographs have been obtained from the gas mols. Se_2, Te_2 and HgCl. The internuclear distances found for Se_2 and Te_2 were 2.19 ± 0.03 A. and 2.59 ± 0.02 A., resp., while for HgCl a sepn. of 2.23 ± 0.03 A. was obtained. Bernard Lewis

The scattering of mesotrons in metal plates. J. G. Wilson. *Proc. Roy. Soc.* (London) **A174**, 73–85(1940).—An extended series of accurate measurements of the scattering of mesotrons, using an expansion chamber, is described. The results are in general agreement with earlier (cf. *C. A.* 34, 228) measurements and confirm to within 4% the theoretical values given by Williams (cf. *C. A.* 33, 8492[1]) for multiple Coulomb scattering. The evidence for the existence of large-angle scattering due to short range forces between mesotrons and nuclear heavy particles (protons and neutrons) is discussed, where the cross section for this type of scattering is estd. to be of the order of 10^{-28} cm.^{2}, which is in agreement with Bhabha's value for a "classical" mesotron theory. On the other hand, no exptl. evidence was found for the large increase of scattering due to short range forces at low mesotron energies given in Heitler's quantum-mechanical treatment. Here, the cross section was found to be less than 10^{-27} sq. cm., and is explained as indicating a failure in the treatment of the charge-exchange which leads to the interaction between charged mesotrons and heavy particles. Frank Gonet

The instability of the meson. Martin A. Pomerantz. *Phys. Rev.* 57, 3–12(1940).—Values of the proper lifetime of the meson have been deduced from a comparison of the intensity of mesons in an inclined direction under air with that in a vertical direction under a superposed Pb shield equiv. in absorbing power to the difference between the masses of the air traversed by the mesons before reaching the app. in the 2 directions. From the exptl. data it is calcd. that the av. proper lifetime of all mesons having energies exceeding 6.1×10^8 e. v. upon reaching the app. is 3.9 ± 0.3 microsec., and the av. for mesons with energies exceeding 11.9×10^8 e. v. is 3.8 ± 0.4 microsec. The lifetime of only those mesons having about 9×10^8 e. v. energy is 2.6 ± 0.8 microsec. A value of roughly 6 microsec. is calcd. from measurements of the no. of disintegration electrons and their secondaries in equil. with the mesons in air. Bernard Lewis

Instability of the mesotron. Mario Ageno, Gilberto Bernardini, Bernardo Nestore Cacciapuoti, Bruno Ferretti and Giancarlo Wick. *Ricerca sci.* 10, 1073–81 (1939).—A counter arrangement was used to measure triple coincidences in cosmic rays at elevations of 500 m. and 3460 m. above sea level, in the vertical direction and at an inclination of 45°. The results are independent of any hypothesis concerning the isotropy of cosmic radiation and confirm the instability of the mesotron. The av. life of this particle is 3–4 microsec. G. M. M.

Spontaneous disintegration of the mesotron. Bruno Ferretti. *Ricerca sci.* 10, 1144–8(1939).—A tentative theory is presented which is based upon the suggestion of Maier-Leibnitz (cf. *C. A.* 33, 2028[4]) that the mesotron disintegrates into an electron, a neutrino and a neutretto. G. M. Murphy

Evidence for the transformation of mesotrons into electrons. E. J. Williams and G. E. Roberts. *Nature* 145, 102–3, 151(1940).—A cloud-chamber photograph is reproduced which shows the transformation of a mesotron of mass 250 ± 70 into an electron. This shows that the mesotron is identical with the particle assumed by Yukawa in his theory of nuclear forces and β-disintegration. G. M. Petty

The equilibrium conditions of the electronic and mesotronic components in different media and at various altitudes. Gilberto Bernardini, Bernardo Nestore Cacciapuoti, Bruno Ferretti, Oreste Piccioni and Giancarlo Wick. *Ricerca sci.* 10, 1010–17(1939).—From expts. the conclusion is drawn that one cannot assume, as is generally done, that the soft component of the cosmic radiation at sea level is due to electrons produced by a spontaneous disintegration of mesotrons with a mean life time of the order of magnitude of 10^{-6} sec. Instead a great part of the soft electronic component at sea level is due to a residue of the primary electronic component of extraterrestrial origin. The same component that produces the mesotrons in the upper atm. also penetrates by a cascade to the lower regions. Robert Simha

The production of soft secondaries by mesotrons. J. R. Oppenheimer, H. Snyder and R. Serber. *Phys. Rev.* 57, 75–81(1940).—I. Cosmic ray evidence shows that the soft component (I), which persists even under great thicknesses of matter, consists primarily of electrons and γ-rays. The observations of the magnitude and variation with depth of I and showers, and of the size and material dependence of bursts lead the authors to believe that mesotrons can transfer a considerable fraction of their energy to I. This probability is roughly independent of the mesotron energy, while under 10^{10} v. the probability of large transfers is much greater (roughly 20 × the former). II. The production of secondaries of energy < 10^{10} v. can be accounted for by the Lorentz contracted Coulomb field of the mesotron, in sweeping over an atom, ejecting a high energy electron, which, however, does not explain the transfers > 10^{10} v. involved in bursts. The authors have developed a theory to show that the mesotron of spin one assocs. with transitions in which the direction of the mesotron spin changes in intrinsic dipole moment; and this dipole field favors high energy transfer (which accounts for bursts). Such a dipole field was found, however, to give probabilities of high energy bremsstrahlung, > 10^{10} v., much too large to be compatible with the observations. III. The authors found it possible to calc. the cross sections for the production of electron secondaries and bremsstrahlung by the intrinsic mesotron dipole field when they made the assumption that coupling of mesotron and the electromagnetic field is small. This assumption should be valid to mesotron energies of ~ 10^{13} v. and hence applicable to bursts. The bremsstrahlung formula, however, fails at 10^{10} v. and cannot be used for bursts, while for energies $10^9 < E < 10^{10}$ v., it does not contradict exptl. evidence. Further, the authors show that it is the largeness of the coupling, and not the occurrence of lengths < $\hbar/\mu c \sim 2 \times 10^{-13}$ cm. that limits the applicability of the quantum mechanics. Frank Gonet

Nature of the electronic components of cosmic radiation. Bernardo Nestore Cacciapuoti. *Ricerca sci.* 10, 1082–9 (1939).—Absorption of cosmic rays was measured at

elevations of 50, 1050, 2050 and 3500 m. above sea level. An anomaly in the curve at the highest elevation seems to be due to the electronic components. The latter at sea level are mostly composed of residues of the primary electronic components. This conclusion is not reconcilable with current theories of the mesotron. G. M. M.

Simultaneous groups of penetrating particles in cosmic radiation. Gleb Wataghin, D. de Souza Santos and P. A. Pompeia. *Ricerca sci.* **10**, 1150(1939); cf. *C. A.* **34**, 1551[6].—Four counters were arranged to measure coincidences in cosmic radiation. At an elevation of 800 m. above sea level in 3 expts., 29, 25 and 6.4 × 10^{-4} coincidences per min. were detected. G. M. Murphy

Large cosmic-ray showers and mesons. A. H. Wilson and F. Booth. *Nature* **145**, 103–4(1940).—The probability of the emission of a very energetic γ-ray when a fast meson collides with a nucleus is calcd. The cross section is proportional to the energy of the meson; for very high energies the energy loss is mainly due to the emission of γ-rays. The bearing of these calcns. on cascade showers in the atm. is discussed. G. M. Petty

Variations of the hard component of cosmic radiation. E. Regener and W. Rau. *Naturwissenschaften* **27**, 803–5 (1939).—Measurements of cosmic radiation 40 m. below water level in Lake Constance for 14 months with 2 ionization chambers, 7.2 and 29.6 atm. CO_2 pressure, resp., spaced 4 m. apart, allow several general observations on hard cosmic radiation. The intensity of the hard component has a double daily period with 2 maxima and 2 minima, equally high, the maxima being at 9–11 a. m. and 10–11 p. m. This daily variation is attributed to a daily variation in the conditions obtaining near the altitude at which the mesotrons causing the radiation are formed (about 16 km. high, 80 mm. Hg pressure). Daily up and down movements in the ionosphere as found from radio echo and aurora borealis are possibly involved in the phenomenon. B. J. C. van der Hoeven

An experimental test of Schremp's theory of cosmic-ray fine structure. H. S. Ribner. *Phys. Rev.* **56**, 1069–73 (1939).—An east-west directional intensity survey was carried out to test Schremp's theory of cosmic-ray fine structure (*Rev. Modern Phys.* **11**, 149–52(1939)) which was expected to yield information concerning the identity of the primary cosmic rays, their energy spectra at infinity, and their interaction with absorbing matter. An app. of high angular resolution was used. In the curve of directional intensity *vs.* zenith angle z, the present results indicate the existence of symmetrical prominences at $z = \pm 20°$ and further suggest that other symmetrically disposed prominences may exist in the neighborhood of $z = \pm 10°$ and $z = \pm 40°$. Bernard Lewis

The binding energy of H^3. Frederick W. Brown. *Phys. Rev.* **56**, 1107–10(1939).—The consts. in the meson type of potential were calcd. by fitting the scattering data for the scattering of slow electrons by protons and the binding energies of H^2 and H^3. Bernard Lewis

Search for a short-range group of protons in the deuteron-deuteron reaction. F. E. Myers, R. D. Huntoon, C. G. Shull and C. M. Crenshaw. *Phys. Rev.* **56**, 1104–6 (1939).—No evidence is found for short-range protons in the D-D reaction with bombarding energies up to 300 e. kv. at angles of 36°, 97° and 142° to the incident deuteron beam. Bernard Lewis

The scattering of protons by protons. III. N. P. Heydenberg, L. R. Hafstad and M. A. Tuve. *Phys. Rev.* **56**, 1078–91(1939); cf. *C. A.* **31**, 28[8]; **32**, 3256[9].—The anomalous scattering of protons by protons carried out earlier by the authors was repeated in the energy region 600 to 900 kv. with a new scattering app. designed for better angular measurements. Bernard Lewis

Deuteron-deuteron, proton-helium, deuteron-helium scattering. N. P. Heydenberg and R. B. Roberts. *Phys. Rev.* **56**, 1092–5(1939).—Measurements were made on deuteron-deuteron scattering at angles between 20° and 45° for incident deuteron energies of 832, 720 and 614 kv. In this range of angles and energies the ratio of the observed scattering to that predicted by classical theory is always greater than unity. At 832 kv. the ratio increases from 1.28 to 15° to 3.98 at 45°. This anomaly could be due to the presence of a short-range repulsive force between the particles in addn. to the Coulomb force. The scattering of protons in He was in agreement with the Rutherford-Darwin scattering formula for 994-kv. protons in the angular range from 20° to 45°. The scattering of deuterons in He showed an anomaly which increased from about unity at 20° to 4.4 at 75°. Bernard Lewis

Low-energy neutrons emitted by beryllium bombarded by α-particles. M. Benini. *Atti accad. Lincei, Classe sci. fis., mat. nat.* **29**, 590 6(1939).—By means of the counter devised by G. Bernardini and D. Bocciarelli (*C. A.* **33**, 4201[5]) the energy of neutrons emitted by Be bombarded by α-particles is found to be 130,000 e. v. < E < 160,000 e. v. A. W. Contieri

The quantitative determination of the neutron moment in absolute nuclear magnetons. Luis W. Alvarez and F. Bloch. *Phys. Rev.* **57**, 111–22(1940).—The authors have extended the magnetic resonance method of detg. nuclear magnetic moments in mol. beams (cf. Rabi, *C. A.* **31**, 4887[1]) to det. the neutron moment, using magnetic scattering to produce and analyze the polarized beam of neutrons. A new method of evaluating magnetic moments in all expts. using the resonance method is described, where the magnetic moment of any nucleus can be detd. directly in abs. nuclear magnetons merely by a measurement of the ratio of 2 magnetic fields: (*a*) that at which resonance occurs in a Rabi-type expt. for a certain frequency and (*b*) that at which protons are accelerated in a cyclotron operated on the nth harmonic of that frequency. The magnetic moment then becomes $\mu = H_b/nH_a$, where n is an integer. The expt. result, based on 2 million counts, is given as $\mu = 1.93_5 \pm 0.02$ abs. nuclear magnetons. The theory of the expt. is developed in some detail, and a description of the app. is given. Frank Gonet

Total and specific ionization of polonium α-particles and their statistical fluctuations. II. J. M. W. Milatz and G. A. W. Rutgers. *Physica* **7**, 131–2(1940)(in English).—Note and correction of p. 536 and p. 547 of previous article (cf. *C. A.* **33**, 9116[2]). Additional measurements on the straggling in range of α-particles emitted by sources of different strength, with sources prepd. by placing Ag foils in a soln. of Po salt during different periods, show that (1) the strength of the source is proportional to the time of exposure of the foil in the soln. and (2) the straggling parameter α increases with increasing strength and finally seems to reach a const. value. Extrapolating the values measured to thickness zero, $\alpha_0 = 0.53$ mm. M. McMahon

Intermediate ions of the atmosphere. A. R. Hogg. *Proc. Phys. Soc.* (London) **51**, 1014–27(1939).—It is shown that (*a*) the smaller nucleated ions in city air exist in sep. groups with distinct mobilities; (*b*) the variation of the mobility of these ions with humidity is such as to lead to the conclusion that the ions are composed of droplets of H_2SO_4; (3) it appears that the ions result from the aggregation of particles contg. about 2200 mols. of H_2SO_4 or multiples thereof. The acid, before and after aggregation, is hydrated to an extent dependent on the temp. and the humidity of the atm. and on the radius of the droplet. M. Farnsworth

Some features of an electrostatic generator and ion source for high-voltage research. I. A. Getting, J. B. Fisk and H. G. Vogt. *Phys. Rev.* **56**, 1098–1104(1939).—A compact generator of the Van de Graaff type is described in which several new features have been incorporated. Bernard Lewis

γ-Rays from beryllium and nitrogen bombarded with deuterons. H. R. Crane, J. Halpern and N. L. Oleson. *Phys. Rev.* **57**, 13–15(1940).—Measurements were made on the Compton electrons ejected from a thin lamina of C by the γ-rays from Be + D and N + D. Lines at 3.45 and 1.0 m. e. v. were found with Be + D and lines at 8.2, 6.6 and 5.1 m. e. v. were found with N + D with a slight indication of 2 other lines at 4.1 and 2.5 m. e. v. Possible ways in which these can be correlated with the

energies of the heavy particles emitted are discussed. Bernard Lewis

Series in nuclear energy levels. K. M. Guggenheimer. *Nature*, **145**, 104–5(1940).—The known nuclear energy levels of B^{10}, Mg^{24} and X^{223} are interpreted as proper values of the rigid rotator, which can thus be applied to nuclei. The moments of inertia are in accordance with the assumption of equal nuclear d. G. M. Petty

Nuclear isomerism in zinc. J. W. Kennedy, G. T. Seaborg and E. Segrè. *Phys. Rev.* **56**, 1095–7(1939).—Zn^{69} has two isomeric states differing in energy by 0.47 m. e. v. The upper state decays into the lower with a half life of 13.8 hrs., emitting a γ-ray which has an internal conversion coeff. of less than 0.1. The lower isomeric state decays into Ga^{69} with a half-life of 57 min. The most probable value for the spin difference between the isomeric states is 5. Bernard Lewis

Nuclear isomerism in selenium and krypton. Alexander Langsdorf, Jr., and Emilio Segrè. *Phys. Rev.* **57**, 105–10 (1940).—The authors have studied the radioactive chain $Se^{83} \rightarrow Br^{83} \rightarrow Kr^{*83}$, and have identified the last as an excited state (Kr^{*83}) of the stable Kr^{83}, have shown the presence of an isomeric pair in $Se^{78 \text{ or } 81}$, and have chemically sepd. the 2 genetically related nuclear isomers and confirmed and identified Se^{83} (cf. Snell, *C. A.* **32**, 1569[6]). Further, they have shown that Kr^{83} and Br^{83} are produced by the fission of U and Th as well as by the bombardment of Se with deuterons and slow neutrons. F. Gonet

The production of radium E and polonium by deuteron bombardment of bismuth. D. G. Hurst, R. Latham and W. B. Lewis. *Proc. Roy. Soc.* (London) **A174**, 126–36(1940).—By use of the Cambridge cyclotron, the reactions occurring when Bi is bombarded by deuterons of energies up to 8.7 m. e. v. have been investigated. The α-particles observed are believed to be emitted by Po, and the reactions taking place are given as: (I) $_{83}Bi^{209}(d,p)_{84}Ra\ E^{210} \rightarrow {}_{84}Po^{210} + \beta$. (II) $_{83}Bi^{209}(d,n)_{84}Po^{210}$, and $_{84}Po^{210} \rightarrow {}_{82}Pb^{206} + \alpha$, as the specimens showed both an initial α-particle activity and a rise of activity with the 5 days' half-life expected from the decay of Ra E. By detg. the amts. of Po formed directly, and indirectly after the decay of Ra E, the authors were able to measure the relative yields of the (d,p) and (d,n) reactions at various energies of the deuteron. The excitation functions for the two reactions have been compared with the values to be expected on theoretical grounds. F. G.

Erratum: The radioactivity of Mn^{56}. R. H. Bacon, E. N. Grisewood and C. W. Van der Merwe. *Phys. Rev.* **57**, 240(1940); cf. *C. A.* **34**, 1555[6]. G. M. Petty

The β- and γ-rays of thorium active deposit. Roger Arnoult. *Ann. phys.* **12**, 241–388(1939).—The phys. properties of the β- and γ-rays of the active deposit of Th were measured. The results are summarized under: (1) the detn. of the abs. energy of a standard ray (ray F of the transformation Th $B \rightarrow C$); (2) a quant. study of the intensity of the conversion groups; (3) a study of the continuous β spectrum emitted in the transformation Th $B \xrightarrow{\beta} C$; (4) a detn. of nuclear energy levels. γ M. Farnsworth

The radioactivity of the thermal waters and gases of the fumarole of the Island of Ischia. Oscar Scarpa. *Ricerca sci.* **10**, 988–91(1939). Robert Simha

A radiometric experiment at Lake Ameno (Island of Ischia). Giuseppe Imbò. *Ricerca sci.* **10**, 936–40(1939). F. C. Nachod

Further measurements on the radioactivity of the waters of the Lake Ameno and of Cetaro. Giuseppe Imbò. *Ricerca sci.* **10**, 992–7(1939); cf. preceding abstr. Robert Simha

γ-Ray measurement of radium. T. H. Oddie. *Proc. Phys. Soc.* (London) **51**, 905–31(1939).—In preference to calcn. exptl. methods have been used for the detn. of the obliquity and absorption corrections that must be applied to the measured content of a rectilinear radioactive source to find the true content. The effect on the correction of variations of the following factors has been studied: (*a*) the distance between the source and the measuring instrument (from 10 to 60 cm.); (*b*) the active length of the container (0 to 10 cm.); (*c*) the equiv. Pb wall-thickness of the cylindrical ionization chamber of vol. 1 l. (6 to 12 mm.); (*d*) the wall-material (Pt, Au or Ag) thickness (0 to 2 mm.) and diam. of the Ra container; and (*e*) the thickness of the wooden source-holder. The effect of scattered and secondary radiation upon the measurements has been found to be small. Percentage corrections derived from the exptl. results are given in tabular form. M. Farnsworth

Quantitative and model data on the classification of isotopes. H. Jensen. *Naturwissenschaften* **27**, 841–50 (1939).—Quant. data on nuclear structure are correlated with the models previously classified. B. J. C. van der Hoeven

The concentration of carbon 13 by thermal diffusion. Alfred O. Nier. *Phys. Rev.* **57**, 30–4(1939).—A thermal-diffusion column employing CH_4 gas has been constructed for the purpose of concg. C^{13}. A detn. of the sepn. factor of the column for various pressures indicated a quant. agreement between expt. and theory. When a reservoir was attached to the top of the column it was possible to produce CH_4 contg. over 4 times the normal amt. of $C^{13}H_4$. Bernard Lewis

Concentration of isotopes by thermal diffusion: rate of approach to equilibrium. J. Bardeen. *Phys. Rev.* **57**, 35–41(1939).—The time-dependent partial differential equation involved in the theory of the operation of a Clusius thermal-diffusion column is discussed. Solns. presented give the concn. of a given isotope at any point in the column as a function of time. Bernard Lewis

The directional relations of the field emission as sign of Bragg interferences in the metallic lattice. Erwin W. Muller. *Naturwissenschaften* **27**, 820–1(1939).—The field emission from monocryst. metal points with spherical tip shows a distinctive spatial pattern. In the center around the (110) direction there is no emission (W monocrystal); likewise the emission around the 4 (211) directions and the (100) directions is of low intensity. Some of the areas of low intensity are sharply delimited, the (100) dark spots within an angle of 2°. If the internal energy for electrons is in a narrow band (about 0.5 e. v. wide) at 7.5 e. v., corresponding to a Broglie wave length of 4.5 A., it follows from the lattice constant (a = 3.18 A.) that the electron wave in 110 direction is extinguished by Bragg interference. For emission of incandescent metal the sum of internal energy and exit work totals about 12 e. v. with Broglie wave length 3.50 A. and consequently a different emission pattern. The emission possibilities along different directions checked by Bragg interference requirements agree well with the observed pattern. B. J. C. van der Hoeven

Experimental study of the scattering of x-rays by crystals. Jean Laval. *Bull. soc. franç. minéral.* **62**, No. 4, 5, 6, 137–253(1939); cf. *C. A.* **33**, 5286[9].—Crystallographic and math. D. W. Pearce

Absorption spectra and characteristic levels of uranium, platinum and tungsten. Yvette Cauchois and Ioana Menescu. *Compt. rend.* **210**, 172–4(1940); cf. *C. A.* **30**, 20[5].—The L_I, L_{II} and L_{III} absorption edges of U, Pt and W were redetd., the results agreeing with those of Sandström (*C. A.* **24**, 1155); thence are deduced the energy levels of the same elements. The results are discussed. C. A. Silberrad

Sources of stellar energy. I. N. Golovin. *Astron. J. Soviet Union* **16**, No. 3, 81–99(1939).—On the basis of the energy derived from atomic nuclear reactions, G. calcs. the possible ages and temps. of the sun and stars. F. H. Rathmann

The theory of the solar corona. A. B. Severnyĭ. *Astron. J. Soviet Union* **16**, No. 4, 1–16 (in English, 16–17) (1939). F. H. Rathmann

Spectrophotometry of the continuous spectrum of Nova Herculis 1934. B. Vorontsov-Vel'yaminov, E. Krinov and O. Cramer. *Astron. J. Soviet Union* **16**, No. 3, 9–17

(1939).—Photographic plates for the period Dec., 1934–April, 1935 are shown. F. H. Rathmann

Determination of the Rydberg constants, e/m and the fine structures of H_α and D_α by means of a reflection echelon. J. W. Drinkwater, Owen Richardson and W. Ewart Williams. *Proc. Roy. Soc.* (London) **A174**, 164–88(1940).—A 40-plate reflection echelon was used to resolve the fine structure of the H_α and D_α emitted by a discharge through a cooled tube contg. He and a trace of H or D. The measurements were made against the red ray of Cd as standard. The wave nos. of the intensity max. of H_α and D_α, measured *in vacuo*, were 15233.067 and 15237.211 cm.$^{-1}$, resp., leading to the values R_H = 109677.58 and R_D = 109707.42 for the Rydberg const. Further derived consts. are 5.48646 × 10^{-4} for the mass of the electron; 1.7591 × 10^7 e. m. u./g. for e/m; 1837.4 for M_H/m; and 109737.27 for R_∞. The observed fine structures of H_α and D_α are blended patterns of the theoretical components, and in the present observations the 4th component is measured in position and intensity for the first time, being 0.04 cm.$^{-1}$ from component 1. C. C. Kiess

Absorption of hydrogen Lyman radiation by atmospheric gases. S. E. Williams. *Nature* **145**, 68(1940).—The absorption by gases of the H resonance line 1215.7 A. was investigated. N is transparent. H_2O vapor absorbs strongly. O and air absorb more strongly than was previously believed. No absorption occurs until the partial pressure of O is about 0.04 mm., and the absorption coeff. varies in the lower part of the absorption range. G. M. Petty

Doppler effect in resonance lines. L. G. Henyey. *Proc. Natl. Acad. Sci. U. S.* **26**, 50–4(1940).—It has generally been supposed in astrophys. applications that the condition of monochromatic radiative equil. is present in the formation of resonance lines. That this is not the case, under conditions when Doppler broadening is present, follows from the fact that the projected velocity and hence the Doppler shift of an atom are not the same along the direction of the scattered ray as along the primary ray. A math. discussion is given of the contribution of scattered light to Doppler broadening. W. F. M.

Intensity measurements of helium absorption lines. H. C. Burger and H. P. van Cittert. *Physica* **7**, 13–16 (1940) (in English).—Transition probabilities in He, derived theoretically by Hylleraas (*C. A.* **31**, 8317[4]), are tested by measuring the intensity ratio of He lines in absorption. Light from a water-cooled He tube is passed through an electrically excited absorption tube contg. He at 1.5 mm. Hg pressure, then through a Lummer-Gehrcke interferometer and finally focused on the slit of a prism spectrograph. For two lines, $2'S - 3'P$ (5016 A.) and $2'S - 4'P$ (3964 A.), having a low metastable level in common, the ratio of the absorption coeffs. is 3.4 ± 0.2. The accordance of this exptl. value with the theoretical one (3.87) is regarded as satisfactory. W. F. M.

The problem of the natural width and the displacement of spectral rays. J. Serpe. *Physica* **7**, 133–44(1940)(in French). W. F. Meggers

The breadth of spectral lines at large densities of a homogeneous gas. V. Fursov and A. Vlasov. *J. Phys.* (U. S. S. R.) **1**, 335–40(1939).—The broadening of the resonance level, caused by dipolar interaction between similar atoms at large densities of the gas, is calcd. The influence of this broadening upon the breadth of spectral lines is discussed and satisfactory agreement between calcd. and observed breadths of Hg lines is reported for vapor pressures of 20 to 80 atms. W. F. Meggers

Infrared arc spectrum of germanium. C. C. Kiess. *J. Research Natl. Bur. Standards* **24**, 1–5(1940)(Research Paper No. 1266); cf. *C. A.* **33**, 5279[6].—The more intense lines of Ge I, which for theoretical reasons are known to exist in the infrared, have now been photographed in the region from 8000 to 12,000 A. and their wave lengths measured. Most of them have been classified as combinations between the previously known terms, $5s^3P^\circ$ and $5s^1P^\circ$ and new triplet and singlet terms of the $5p$ electron configuration. The yellow lines between 5260 and 5800 A., previously observed by Lunt (*C. A.* **19**, 3220) in spark and discharge tube sources, are found to belong to Ge I and probably owe their origin to the $5s - 6p$ transition. The wave lengths of some yellow and red Ge II lines are also given. C. C. Kiess

Magnesium-like spectra of chlorine, potassium, calcium and scandium. W. L. Parker and L. W. Phillips. *Phys. Rev.* **57**, 140–1(1940).—About 80 lines belonging to the triplet system of the Mg-like ions, Cl VI, K VIII, Ca IX and Sc X have been identified and term values for each ion have been reported with respect to the $3s3p^1P_0$ level. Frank Gonet

The spectra of yttrium V and zirconium VI. F. W. Paul and W. A. Rense. *Phys. Rev.* **56**, 1110–13(1939).—Spectrograms covering the region from 150 A. to 1000 A. were obtained with a 3-meter grazing incidence vacuum spectrograph having a dispersion of 1.0 A./mm. at 500 A. Bernard Lewis

Isotope shift in magnesium. John P. Vinti. *Phys. Rev.* **56**, 1120–32(1939).—A theoretical investigation to det. whether nuclear motion alone can account for the observed fine structure in Mg. It is concluded that the quantum-mech. theory of nuclear motion, without the assumption of non-Coulomb nuclear fields or of nuclear spins, gives a good qual. explanation of fine structure in Mg. Bernard Lewis

Zeeman effects in complex spectra at fields up to 100,000 gausses. George R. Harrison and Francis Bitter. *Phys. Rev.* **57**, 15–20(1940).—A newly constructed electromagnet of the Bitter type has been arranged to give fields up to 100,000 gausses, uniformly to 1% over a vol. of 25 cc. A special type of horizontal arc, with electrodes of salts compressed in Ag powder, is operated at 4 amps. and furnishes light transversely to the field to 3 grating spectrographs which can cover the range 2000 to 8000 A. U. in a single exposure. Plane-polarized components of the light are sepd. with a 2-inch quartz Rochon prism, and exposures of 5 to 30 min. give dense spectrograms at resolutions of 100,000 and greater. Plates in the ultraviolet region have been obtained for Ce, Cb, Er, Eu, Gd, Fe, Nd, Pr, Rh, Ru, Th, W, and Yb. On most of the plates lines of the second and third spectra are more in evidence than those of the first, and air lines are prominent. Typical portions of a Rh plate at 90,500 and 70,000 gausses are shown and data are given for a no. of Ce, Rh and Ru lines. Bernard Lewis

An interpretation of the spectral sequence for the late-type stars. Yosio Huzita. *Japan. J. Astron. Geophys.* **17**, 17–57(1939).—The spectra of stars belonging to the main sequence, i. e., to classes O, B, A, F, and G, are adequately explained on the basis of temp. alone. The spectra of late-type stars, from class G through the R—N, K—M, and K—S branches, exhibit prominently the bands of either TiO, ZrO, C_2 or CN. These spectra are here interpreted not only on the basis of temp., but also on the relative abundance of O, N, and C. C. C. Kiess

The fundamental rotation-vibration band of nitric oxide. R. H. Gillette and Eugene H. Eyster. *Phys. Rev.* **56**, 1113–19(1939).—The fundamental rotation-vibration band of NO was measured with the high dispersion of an echellette grating spectrometer, and was given a complete analysis. The resulting consts. are combined with those derived from the existing electronic data to yield the following mol. consts. for the normal state of the mol.: ω_e = 1904.03 ($^2\Pi_{1/2}$) cm.$^{-1}$; $\omega_e x_e$ = 13.97 cm.$^{-1}$; $\omega_e y_e$ = −1.20 × 10^{-3} cm.$^{-1}$; B_e = 1.7046 cm.$^{-1}$; I_e = 16.423 × 10^{-40} g. cm.^{2}; r_e = 1.1508 A. Bernard Lewis

Two new electron levels of the molecule of carbon monoxide. V. M. Chulanovskiĭ. *J. Phys.* (U. S. S. R.) **1**, 341–6(1939).—About 30 bands in the CO spectrum observed from 1300 to 1000 A. are analyzed and interpreted. A system of bands of the type $^1\Sigma \rightarrow {}^1\Sigma_i$ with electron level ν_{00} = 90,866 cm.$^{-1}$ is established and a 2nd system of the type $^1\Pi \rightarrow {}^1\Sigma$ with ν_{00} = 98,791 cm.$^{-1}$ is described. W. F. Meggers

The spectrum of rubidium hydride, RbH. I. Analysis. A. G. Gaydon and R. W. B. Pearse. *Proc. Roy. Soc.* (London) **A173**, 28–37(1939).—A discharge through the

mixed vapors of Rb and H at a few mm. pressure evoked emission of an open, many-lined spectrum which is attributed to the RbH mol. Nearly 2000 lines have been measured in the interval from 4600 to 6600 A., the max. intensity occurring in the yellow. A close study of the apparently confused mass of lines reveals that many of them belong to the P and R branches, all shaded toward the red, of a $^1\Sigma \rightarrow {}^1\Sigma$ transition, the branches being well represented by the usual type of formula for rotational structure. The wave nos. of the origins of the strong bands are accurately given by the vibrational formula: $\nu = 18906.4 + (244.6u' + 4.1u'^2 - 0.169u'^3 - 0.000838u'^4 + 0.000116u'^5) - (936.77u'' - 14.15u''^2 + 0.075u''^3)$. The excited state exhibits anomalies similar to those observed for the other alk. hydrides. **II. Potential curves, wave functions and intensity distribution.** *Ibid.* 37–47.—The potential curves for the initial and ground states have been constructed with the aid of the mol. consts. found above. For the vibrational levels of each state the appropriate wave functions have been calcd. These in turn have been used to calc. the theoretical band intensities which are in good agreement with the observed. The strongest bands fall on an open parabola of the Franck-Condon type. Two subordinate parabolas mark the loci of secondary and tertiary distributions of fairly strong bands. C. C. Kiess

The molecular spectrum of iodine excited by fluorescence (in the presence of nitrogen) and by active nitrogen. A. Elliott. *Proc. Roy. Soc.* (London) **A174**, 273–85 (1940).—The vapor of I was excited to fluorescence by exposing the quartz tube contg. it mixed with N to the light of a condensed spark between Al electrodes. The light was analyzed with quartz and glass prism spectrographs. Between 2520 and 2730 A. a compact system of bands, shaded toward the red, was observed. The band heads are given by $\nu = 39709 + 96.5\,(v' + 1/2) - 0.3\,(v' + 1/2)^2 - 158\,(v'' + 1/2) + 1.1\,(v'' + 1/2)^2$. The previously known continuum with max. at 3425 A. is now resolved into a system of bands extending from 3040 to 3450 A., likewise shaded toward the red, and given by $\nu = 33744 + 104\,(v' + 1/2) - 0.2\,(v' + 1/2)^2 - 214.26\,(v'' + 1/2) + 0.592\,(v'' + 1/2)^2$. This system is analogous to the 2580-A. continuum of Cl_2 and represents a $^1\Sigma_u^+ \rightarrow {}^1\Sigma_g^+$ transition. A similar but fainter system of bands between 4041 and 4321 A. makes up the previously known 4300-A. continuum. A fourth system extends from 4440 to 4630 A. and consists of bands shaded toward the violet. The emitter of these is probably not the I mol. C. C. Kiess

Ultraviolet absorption spectra of acridine, ethyl-, pentadecyl-, and phenylacridine. G. A. Dima and P. Pogăngeanu. *Bull. sect. sci. acad. roumaine* **21**, 38–40 (1938–39).—Absorption of acridine and its derivs., ethyl-, pentadecyl-, and phenylacridine in alc. soln. is studied in the range 2500–3880 A. by means of an underwater spark and a quartz spectrograph. The general aspect of the spectrum is the same in all cases, but in the derivs. the bands are displaced toward longer waves. This is illustrated by measured wave lengths of 8 bands. W. F. Meggers

The ultraviolet absorption spectra of vapors of monohalogenic derivatives of toluene. I. H. Tintea. *Bull. sect. sci. acad. roumaine* **21**, 219–22 (1938–39).—By use of a quartz spectrograph, a 1-m. absorption tube with quartz windows, and an underwater spark, the ultraviolet absorption of certain derivs. of toluene in the vapor state is investigated for the first time. In the spectrum of *p*-fluorotoluene 173 bands were measured, in *p*-chloro- 116, and in *p*-bromotoluene 91 bands. Formulas are adjusted to give a satisfactory representation of the majority of observed bands. W. F. Meggers

The water-vapor molecule. Byron T. Darling and David M. Dennison. *Phys. Rev.* **57**, 128–39 (1940).—Math. The problem of the vibration-rotation spectrum of water vapor is treated by means of the theory of semi-rigid polyatomic mols. developed by Wilson and Howard (cf. *C. A.* **30**, 3288[4]). The agreement between the calcd. and exptl. values of the interaction const. was found to be remarkably good (4%). The calcd. valence angle is 104°31′ and the O—H distance 0.9580 A. F. G.

Investigations of infrared spectra (2.5–7.5 μ). Absorption of water. J. J. Fox and A. E. Martin. *Proc. Roy. Soc.* (London) **A174**, 234–62 (1940).—A grating spectrometer was used to observe the infrared absorption spectrum of H_2O in the gaseous, liquid, and solid state and also in soln. in CCl_4. A study of the bands at 3, 4.7 and 6 μ at various temps. shows that the 3-μ band shifts toward shorter wave lengths and the other two toward longer wave lengths with increasing temp. This effect is attributed to a reduction of the OH valency frequencies by the H bonds between the mols. and to an increase of the angular deformation frequency owing to the constraints imposed by surrounding mols. The 2 bands at 2.7 μ, reported by others for solns. in CCl_4, have been re-observed and are found to exhibit no rotational structure, but are shifted 40 to 50 $cm.^{-1}$ toward lower frequencies from their position in the vapor state. They are weakest in the vapor state and increase in intensity with mol. assocn. and reach their max. for ice. C. C. Kiess

An investigation of the complex structure of the O-H harmonic bands of substituted alcohols, and of the effect of temperature on the relative intensities of the multiplet components. Lloyd R. Zumwalt and Richard M. Badger. *J. Am. Chem. Soc.* **62**, 305–11 (1940).—An investigation has been made of the complex structure of the third harmonic O-H bands of ethylene chlorohydrin and bromohydrin, methylcellosolve, trimethylene chlorohydrin and bromohydrin, propylene chlorohydrin and *sym*-glycerol dichlorohydrin. These substances were all studied in the vapor state. In all cases except trimethylene chlorohydrin and bromohydrin the substitution of a halogen or a methoxy group in the alc. has given rise to one or more new O-H bands. Photometric studies have been made of the effect of temp. on the relative intensities of the components of the O-H bands in *o*-chlorophenol, propyl alc. and ethylene chlorohydrin. It is found that in the vapor state at 180° the energy and free energy of the trans form of *o*-chlorophenol exceed those of the cis form by 3.9 ± 0.7 and 2.8 ± 0.5 kg.-cal., resp. A. B. Garrett

The infrared absorption spectrum of methylamine vapor. C. R. Bailey, S. C. Carson and E. F. Daly. *Proc. Roy. Soc.* (London) **A173**, 339–48 (1939).—The absorption spectrum of CH_3NH_2 vapor was observed in the infrared from 1 to 26.5 μ with a prism spectrometer. The wave lengths, frequencies and profiles of the observed bands are presented in the tables and graphs. A close representation of the spectrum is found in a mol. model in which there are 2 parallel and 2 perpendicular vibrations assocd. with the CH_3 group, 3 approx. perpendicular vibrations with the NH_2 group, and the remaining vibrational modes arising from the translations and rotations of the 2 groups relative to one another and of the mol. as a whole. The frequency corresponding to the torsional mode of the mol. lies too far in the infrared for observation, but 3 of its harmonics lie in the observed range and lead to a value of 11.52 cal./g. mol. for the sp. heat of CH_3NH_2, in good agreement with Felsing and Jessen's value (*C. A.* **28**, 30[4]). C. C. Kiess

Infrared absorption spectra of drying oils. D. L. Gamble and C. E. Barnett. *Ind. Eng. Chem.* **32**, 375–8 (1940).—Results are given indicative of the possibilities of the method of infrared absorption spectra as applied to a study of phys. and chem. changes which take place during the formation and decompn. of films of drying oils. Advantages of this method are that it entails no chem. action on the paint film and permits study of the effects of infrared-transparent pigments on the changes occurring in the vehicle during drying and aging. Absorption spectra from 2 to 12 μ are shown for linseed, China wood and oiticica oils, and for 4 glyceryl esters. Changes in the infrared absorption spectra caused by exposure of the esters to ultraviolet light and oxygen are discussed. They are believed to be due to polymerization of the ester to large mol. aggregates which effectively scatter the infrared radiation. W. F. Meggers

The partial and total emissive power of various sub-

stances. IV. A. Carelli. *Atti accad. Lincei, Classe sci. fis., mat. nat.* **29**, 664–71(1939).—The emissivity of various substances in the infrared region (1 μ–7 μ) for temps. of 500°–1200°K. is detd. and the results are plotted. Among the substances measured were: $CaSO_4$, $SrSO_4$, CaO, MgO, BeO, ZnO, FeO, Cu_2O and CuO.
A. W. Contieri

What has the Raman effect accomplished in the ascertainment of constitution? K. W. F. Kohlrausch. *Österr. Chem.-Ztg.* **42**, 345–50(1939).—A review of the uses of Raman spectra in the detn. of chem. constitution, mol. configuration, rotational isomerism, characteristic frequency shifts and symmetry. J. H. Hibben

Recent developments and applications of the Raman effect. James H. Hibben. *Pubs. Am. Assoc. Advancement Sci.* No. 7, *Recent Advances in Surface Chemistry and Physics* 117–25(1938).—The applications of Raman spectrum methods to the detn. of the constitution of org. and inorg. compds. is discussed. Coupling between H_2O mols. which exist normally in a quasi-cryst. arrangement is shown to be affected by solutes and temp. Different forms of nitric, sulfuric and pyrosulfuric acids are present in solns. of different concns. J. H. Hibben

The α-β transformation of quartz. C. V. Raman and T. M. K. Nedungadi. *Nature* **145**, 147(1940).—The scattering of the Hg line 4358 A. by quartz was observed at −192°, 25°, 100°, 200°, 300°, 420° and 530°. The behavior of the 200 cm.$^{-1}$ line shows that the binding forces which det. the frequency of the corresponding mode of vibration of the crystal lattices diminish rapidly with rising temp. The increasing excitation of this particular mode of vibration with rising temp. and the deformations of the at. arrangement resulting therefrom are in a special measure responsible for changes in the thermal expansion, Young's moduli, and the piezoelec. activity between 200° and 575°, as well as for the α-β transformation at 575°.
G. M. Petty

Raman spectra of fused nitrates. P. A. Moses. *Proc. Indian Acad. Sci.* **10A**, 71–6(1939).—Raman shifts observed from fused KNO_3 and $NaNO_3$ occurred at $\Delta\nu$ 700, 1050, 1400 and 1670 cm.$^{-1}$, the first and third corresponding to the 2 degenerate vibrations and the second to the sym. one. The 4th frequency at $\Delta\nu$ 1670 is the first overtone of the forbidden Raman frequency at $\Delta\nu$ 835. Fused $Al_2(NO_3)_3.9H_2O$ gives rise to the same lines as the alkali nitrates with the exception of $\Delta\nu$ 1670, which was unobserved because of the interference from the water bands. The depolarization factors for the sym. vibrations are near 0.2 and for the degenerate vibrations near 0.9 and for the overtone near 0.5. Wings were reported for all 3 nitrates at $\Delta\nu$ 7, 14, 21, 28, 35, 42, 49 and 56; for KNO_3 and $NaNO_3$ there was also observed 63, 70, 77, and for $NaNO_3$ alone the additional frequencies at 84, 91, 98, 105, 112 and 119 cm.$^{-1}$ were found. The intensity of $\Delta\nu$ 14 is much greater than that of any other wing. Different portions of the wings in the nitrates were found to be depolarized to the extent of 86%, in agreement with the theory. J. H. Hibben

Raman effect in relation to crystal structure. I. Calcite and sodium nitrate. B. Sundara Rama Rao. *Proc. Indian Acad. Sci.* **10A**, 167–75(1939).—Molten and cryst. $NaNO_3$ yielded, resp., the following Raman frequencies and intensities in wave no. cm.$^{-1}$: 718 (2), 1052 (10), 1365 (2), 1658 (1/2); 94 (3), 185 (7), 718 (7), 1068 (10), 1381 (8) and 1672 (5). Cryst. calcite yielded $\Delta\nu$ 155 (5), 282 (10), 709 (3), 1084 (8), 1434 (1) and 1754 (1/2). There is a diminution of all internal frequencies of $NaNO_3$ except $\Delta\nu$ 718 in the molten state as compared with the cryst. one and a corresponding decrease in the relative intensities of $\Delta\nu$ 1382 and 1672. Two lattice vibrations were observed in cryst. $NaNO_3$ and $CaCO_3$. These correspond to the longitudinal motions of the RO_3 groups in a direction traverse to the trigonal axis and to a rotary type of motion of these same groups. The lowest Raman shifts are assigned to the longitudinal mode of oscillation and the next higher Raman frequency to the rotary mode. The intensity of the Raman line arising from this type will be governed by the optical anisotropy of the CO_3 or NO_3 groups. The higher frequencies in calcite indicate that the cryst. forces are stronger in it than in $NaNO_3$.
J. H. Hibben

Raman spectrum of neutral tungstates, crystalline or in aqueous solution. Marie Theodoresco. *Compt. rend.* **210**, 175–7(1940); cf. *C. A.* **31**, 35[5]; **33**, 4873[5].—In similar fashion the Raman spectra of $Na_2WO_4.2H_2O$ solid or in soln., and of $SrWO_4$ were detd. Whether anhyd., hydrated or in soln. the WO_4^{--} ion is probably a tetrahedron but more or less deformed. C. A. Silberrad

Polarization of Raman lines in relation to molecular structure: $SOCl_2$, CH_3Cl and BCl_3. K. Venkateswarlu. *Proc. Indian Acad. Sci.* **10A**, 156–66(1939).—The Raman shifts in wave no. cm.$^{-1}$, intensities and degrees of depolarization for $SOCl_2$ are, resp., 194 (10) (0.78), 283 (8) (0.90), 344 (10) (0.21), 439 (8) (1.0), 489 (8) (0.14), 1231 (10) (0.26). If the pyramidal model for the structure is assumed, the spectrum should contain 6 lines, 4 of which should be polarized and 2 completely depolarized. If the mol. has a plane structure, there should be 3 polarized and 3 depolarized lines, which is in accordance with the observation. The frequencies observed in wave no. cm.$^{-1}$ from CH_3Cl were 714 (4) (0.28), 1097 (1) (*P*), 1379 (2) (*P*), 1428 (0) (*D*), 2957 (5) (0.18) and 3028 (1) (0.80). If CH_3Cl resembles $CHCl_3$ there should be 3 polarized and 3 depolarized lines corresponding to a pyramidal structure coming under the point group C_{3v}. V. regards $\Delta\nu$ 2957 (5) as an overtone of 1428 (0) because it is polarized and rejects 1428 as an overtone of 714 because it is depolarized. The 6 fundamentals of the pyramidal CH_3Cl mol. are considered to be $\Delta\nu$ 714, 1097, 1379, 1428, 2815 (unobserved) and 3028. The abnormal intensity as an overtone of $\Delta\nu$ 2957 is explained on the basis of its proximity to another fundamental at 2880 cm.$^{-1}$. BCl_3 is considered as having a configuration corresponding to a plane equilateral triangle with sym. D_{3h} and should have 1 polarized and 2 depolarized Raman lines. Two lines were observed, $\Delta\nu$ 253 and 471 having polarization values of 0.80, 0.30, resp. An addnl. line at 950 cm.$^{-1}$ observed by others was not obtained. J. H. Hibben

Studies on the Raman effect. CII. Benzene derivatives. 14. E. Pendl and G. Radinger. *Monatsh.* **72**, 378–84; *Sitzber. Akad. Wiss. Wien, Math.-naturw. Klasse*, Abt. IIb, **148**, 76–82(1939); cf. *C. A.* **33**, 6719[1].—The intensities and the Raman spectra in cm.$^{-1}$ were reported for the following compds. *n*-, *sec*-, and *tert*-butylbenzene, *p*-fluorobenzoyl chloride, *m*-difluorobenzene, *m*-phenylenediamine, trifluorophenylmethane, 1-chloro-4-methoxy-5-fluorobenzene and 1-methyl-2-chloro-4-fluorobenzene. The spectra obtained from these substances and other di- and tri-substituted derivs. of benzene are compared. All the benzoyl chlorides have a doublet carbonyl frequency near $\Delta\nu$ 1730 and 1775 increasing in magnitude if the substituents in the *p*-positions to the carbonyl group are a halogen of increasing mol. wt. J. H. Hibben

Experimental contributions to the problem of chelation VIII. Raman spectrum of some carbonylic derivatives of naphthalene. R. Manzoni Ansidei. *Boll sci. facoltà chim. ind., Bologna* **1940**, No. 1 2, 23–8.—In continuation of previous investigations (cf. *C. A.* **33**, 9138[3]) Raman spectra of Me α-naphthyl ketone (I), Me β-naphthyl ketone (II), Ph α-naphthyl ketone (III), Me 2-hydroxy-1-naphthyl ketone (IV), Me 2-hydroxy-3-naphthoate (V), and α-naphthyl acetate (VI) were detd. and the chelation (H bond, i. e., ring formation between CO groups and H atoms of neighboring groups) was studied. As could be expected, lines characteristic for chelation between neighboring CO and OH groups were clearly established in the compds. IV and V. Observations in I III and VI indicate chelation in these compds. between the CO group and the H of the naphthalene nucleus in *o*-position to the CO group. Dora Stern

Constitution of peptides. II. Raman spectra and structure of amides. Charles Sannié and V. Poremski. *Bull. soc. chim.* **6**, 1629–49(1939); cf. *C. A.* **31**, 6111[9].—The Raman spectra of acetamide, Et and diethyl acetamide, and acetamide imino ether were obtained in a pure state and in solns. of diverse solvents under diverse condi-

tions. In the spectral region below 1500 cm.$^{-1}$ the spectra are not very sensitive to environmental conditions, but between 1500 and 1750 cm.$^{-1}$ there are several bands which vary in no., intensity and position with the nature of the amide, substituted or not, and the exptl. conditions. Several forms of amides are assumed: imino alc., resonance, excited, and true amide forms together with a complex in aq. solns. The spectra indicate a C=N linkage in all forms except that of the true amide which is present in small quantities only in dioxan solns. of acetamide and propionamide. J. H. Hibben

Band spectra of cathodoluminescence. S. T. Henderson. *Proc. Roy. Soc.* (London) **A173**, 323-38(1939).—ZnS phosphors contg. small amts. of Cu, Ag, Au, Pb or Mn as activators, were excited to fluorescence by exposure to cathode rays, and also to the ultraviolet rays from a Hg arc. The emission bands were recorded photographically and were found to exhibit intensity distributions similar to Gaussian error curves. When excited by ultraviolet light the fluorescent max. are shifted to higher frequencies as compared with cathode-ray excitation. Similar shifts are noted when the phosphor is cooled. C. C. K.

Luminescence and absorption of zinc and cadmium sulfides and their solid solutions. F. A. Kröger. *Physica* 7, 1-12(1940) (in English).—At −180° a new emission has been found from CdS-ZnS solid solns. This consists of at least 5 equidistant bands, the short limit of which coincides with the long limit of the fundamental absorption band. ZnO shows a similar emission in the ultraviolet. **Luminescence and absorption of solid solutions in the ternary system ZnS CdS MnS.** *Ibid.* 92-100(1940) (in English).—A phase diagram of the system is given. The colors of the powders range from yellow for pure CdS to orange for the max. amt. of MnS. The fundamental absorption region shows 2 bands, one in ZnS and CdS, the other in MnS. An emission band at room temp. varies in frequency with the compn. of the solid solns. ranging from blue to infrared. This is ascribed to the crystal lattice itself. Gregg M. Evans

Significance of nonhomogeneities of crystals for the photochemistry of the solid phase. S. M. Moskovich. *Uspekhi Khim.* 8, 719-30(1939).—M. discusses exptl. data on the alkali halide crystals. F. H. Rathmann

The photochemical oxidation of hydrogen. Hilton A. Smith and A. Napravnik. *J. Am. Chem. Soc.* 62, 385-93 (1940); cf. *C. A.* 29, 4675[8].—Data are presented on the quantum yields of the individual products at elevated temp. and at room temp. The wave length of light used was 1719-1725 A. and the total pressure of the reaction mixt. was varied from 1140 to 95 mm. In general, with increasing O content, the quantum yields of ozone increase while those of H_2O_2 and H_2O decrease. Lowering of the total pressure tends to increase the H_2O_2 and H_2O yields, apparently at the expense of the ozone. At pressure of 190 mm. and less, the formation of H_2O shows chain characteristics. The temp. coeff. for the formation of the individual products was also studied over the range 25 to 280°. The formation of ozone has a neg. temp. coeff. while those of H_2O_2 and H_2O are pos. At total pressure of 190 mm. and in a 10% 90% O-H mixt., the temp. coeff. of H_2O_2 and H_2O formation increases with great rapidity at temps. above 230°. The primary reaction is the rupture of an O mol. to form 2 O atoms (cf. *C. A.* 23, 4855). This is followed by interaction of the atoms formed with mols. of O and H. The O atom will react with O mols. to form ozone on triple collisions only (cf. *C. A.* 24, 4224). It is necessary to assume that the third body is an O mol. rather than a H mol. The result of the action of H atoms on a mixt. of H and O at room temp. and ordinary pressures is the formation of H_2O_2 (cf. *C. A.* 27, 926). The relation of the direct photochem. reaction to the Hg-sensitized and the explosive reactions is discussed.
A. B. Garrett

Photosynthesis of the esters of cholesterol. Augusto Banchetti. *Ricerca sci.* 10, 1045(1939).—A soln. contg. 38.6 g. cholesterol and 13.6 g. phenylacetic acid in 200 cc. benzene was exposed for 5 months to solar radiation. The different products were sepd. by fractional crystn. Phenylacetate of cholesterol not yet known could be isolated. It crystallizes from an alc.-ether mixt. in small rectangular prisms which are transparent and colorless, without water of crystn. The crystals m. 119-120° and have an optical rotatory power $[\alpha]_D^{15°} = -28.5°$ (2% in chloroform). About 10% of the cholesterol is esterified. One also obtains a very small amt. of an oily substance with fruit odor which could not be identified. Robert Simha

The emission spectrum of hydrocarbon flames. E. C. W. Smith. *Proc. Roy. Soc.* (London) **A174**, 110-25 (1940).—The emission of stationary and explosion flames of ethylene in air, enriched air and O, and of the explosion flames of propane in air, was examd. and the explosion limits of these mixts. were detd. The chem. analysis, carried out by dilg. the condensate caught in a trap, showed that the formation of both acid and aldehyde passed through a min. in the region of the "theoretical" $C_2H_4:3O_2$ mixt. The amt. of acid formed rose regularly as the mixt. was progressively weakened or enriched; the total aldehyde formation, on the other hand, increased very rapidly with the richer mixts., and with weaker mixts. the aldehyde also increased, but to a much smaller extent. S. suggests that the C deposit observed at pressures in excess of some crit. value with ethylene mixt. might be due to the polymerization of the C_2 mol., formed from $C_2O_2 \rightarrow C_2 + CO_2$. It is also suggested that the "ethylene flame bands" which also occur in the spectra of propane and other hydrocarbon flames are emitted by an isomeric formaldehyde mol., HC.OH. A detailed description of app. and procedure is given. Frank Gonet

Chemical activation by isomeric radioactive transition; the reaction of bromine 80 (18 minute half-life) with carbon tetrachloride. John E. Willard. *J. Am. Chem. Soc.* 62, 256-61(1940).—The radioactive transition from Br^{80} (4.4 hrs.) to Br^{80} (18 min.) activates Br in such a way as to enable it to react with CCl_4. Decay and growth curves of the activities involved give consistent proof of the existence of the reaction. The reaction is independent of temp. and has an efficiency about one-third as great in the solid phase as in the liquid phase. Only those Br^{80} (18 min.) atoms react which are produced as a result of the emission of a conversion electron. These data indicate that the recoil energies, previously thought to account for chem. activation by the isomeric radioactive trausition of Br, are found to be too small to do so (cf. *C. A.* 33, 2799[9]).

Raman effect of hydrocarbons and analysis of liquid fuels (Vol'kenshtein) 22. Spectral analytical investigations and luminescence of fluorite and apatite (Haberlandt) 8. Adsorption of electrolytes on silicic acid, on sesquioxides, and on their mixts. [absorption spectra of adsorbed colored salts] (Kargin) 2. Photochemistry of azides of heavy metals (Moskovich) 5. Ra, U and Po in Canada (Kohl) 8. Action of Rn on polymethylenes—cyclobutane and cyclobutene (Heisig) 10.

Liechti, Adolf, and Minder, Walter: Röntgenphysik. Vienna: J. Springer. 308 pp. M. 30; bound M. 31.80.

Rice, Oscar K.: Electronic Structure and Chemical Binding. New York: McGraw-Hill Book Co. 511 pp. $5.00.

Fluorescent material suitable for electric discharge devices. Gorton R. Fonda (to General Elec. Co.). U. S. 2,184,274, Dec. 26. Ca tungstate or molybdate is used in a mixt. also contg. Sa about 0.5-3% and Pb about 1% as activators of fluorescence.

Opaque materials for x-ray and radium work or the like. Edward R. Dillehay and Geo. M. McFedries (to Richardson Co.). U. S. 2,183,790, Dec. 19. A layer of Pb is used with a decorative panel of condensation resinous compn., the Pb being coated with an adhesion-promoting metal such as Zn, Cu or brass and bonded to the panel by a bonding substance such as a latex or rubber cement.

4—ELECTROCHEMISTRY

COLIN G. FINK

Electrochemistry and chemical industry. J. G. Hoogland. *Chem. Weekblad* **37**, 66–9(1940).—An address. E. H.

Electrometallurgy. Arthur A. Center. *Eng. Mining J.* **141**, 85–7(1940).—Al production expanded during 1939; the anodic oxidation of its alloys was studied. 2 Progress in 1939 of the electrometallurgy of Sb, Be, Cu, Fe, Pb, Mg, Mn, Ni, Sn and Zn is noted briefly. W. H. Boynton

The electric furnace in the steel foundry. Frederick A. Melmoth. *Trans. Electrochem. Soc.* **77**, 6 pp.(preprint) (1940).—Elec. melting of steel for castings is a rapidly expanding industry. Elec. furnace operation is now closely regulated and duplication of product is easily attained. 3 In spite of the very low S and P specifications for metal to be melted in the acid-lined furnace, lower costs and other outstanding advantages of the acid-lined furnace have led to a wide-spread use of this furnace. However, castings from basic-lined elec. furnaces are readily duplicated. They are very responsive to heat-treatment, developing the max. possible combination of strength and ductility. C. G. F.

The development of the electric-arc steel furnace during the last ten years. A. Driller. *A E G Mitt.* **1939**, 422–9. —A review. C. G. F. 4

Plural compositions from a new melting process. Vere Browne and Harry S. Blumberg. *Metal Progress* **37**, 163–8(1940).—Single ingots of two or more compns., called "Pluramelts," integrally bonded together, are produced by a new elec.-furnace melting technique. Thus Cr-Fe and Cr-Ni-Fe stainless alloys are bonded to soft or medium steel, and hard tool-steel types are bonded to soft 5 steel bases. Metallurgical details are not given. W. A. Mudge

Rate of oxidation in the high-frequency induction furnace. H. Weitzer. *Stahl u. Eisen* **59**, 1353–8(1939).—Data on oxidation losses for C, Mn, Cr, Ni, Co, W, Mo, Ta, Cb, Zr, and Ti are given for induction furnace and elec. arc furnace melts. The rates of oxidation loss are greater for the elec. arc furnace. S. Epstein 6

A furnace for micro-Carius determinations. Julius A. Kuck and Maurice Griffel. *Ind. Eng. Chem., Anal. Ed.* **12**, 125–6(1940).—Details of construction are given for an elec. furnace which heats up to 250° in 15 min. and cools down from 300° to room temp. in the same time. T. H. Dunkelberger

Making magnetite electrodes. G. A. Volin and D. D. Kaganov. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 37–40 (1939).—Fe_2O_3 ore is fused with Fe powder to produce 7 Fe_3O_4. The melt is poured into molds and kept above 850° for 2–3 hrs. and then cooled slowly. This treatment prevents cracking of the electrodes. If the ore contains more than 95% Fe_2O_3, C can be used instead of Fe. Presence of Al_2O_3 or SiO_2 weakens the electrodes. H. M. L.

When and why is electric heat-treatment preferred. K. Mitlehner. *A E G Mitt.* **1939**, 389–92.—Gas- or coal-heated furnaces have atms. that may have a deleterious 8 effect on the metal being heat-treated. For high-quality metal products, elec. heating is recommended. C. G. F.

Calculating the heat-energy requirements of electric-resistor furnaces. K. A. Lohausen and G. Schumann. *A E G Mitt.* **1939**, 392–6.—Mathematical relations and many curves are given. C. G. F.

Conveyer equipment for low-temperature electric furnaces. K. A. Lohausen. *A E G Mitt.* **1939**, 396–402. C. G. F. 9

Metallic conveyer belts for low-temperature electric furnaces. W. Kugler. *A E G Mitt.* **1939**, 402–6. C. G. F.

Protective atmospheres for low-temperature electric furnaces. G. Simon. *A E G Mitt.* **1939**, 407–13.—Elec. bright annealing practice has rapidly increased. The gases used comprise H, dissocd. NH_3, partially oxidized NH_3, partially burnt propane, partially burnt illuminating gas and water gas. Heat-treatment in a gas atm. not only prevents oxidation but can be employed for cementation or nitriding. Detailed data are appended. C. G. F.

Small low-temperature electric furnaces for hard soldering. K. A. Lohausen. *A E G Mitt.* **1939**, 414–15.—The protective atm. is dissocd. NH_3. C. G. F. 2

Temperature regulators for electric ovens. K. A. Lohausen and G. Schumann. *A E G Mitt.* **1939**, 415–19. —A review. C. G. F.

Low-frequency induction furnaces. M. Krueger. *A E G Mitt.* **1939**, 419–22.—A review. C. G. F.

High-temperature resistance-type electric laboratory furnaces. Wallace M. Hazel and Wm. J. O'Leary. *Ind. Eng. Chem., Anal. Ed.* **12**, 109–12(1940).—For high temp. fusions, ignitions and combustions internally wound Al_2O_3-core furnaces with exposed coiled-wire winding running parallel to the axis of the furnace attain temps. up to 1500° depending on the resistance wire (NiCr, Pt, Mo, etc.) used. Details of construction, valuable hints on operation and operating data are given. D. Margolis

New electroplating products and processes developed in 1939. Walter R. Meyer. *Metal Ind.* (N. Y.) **38**, 3–11(1940). C. B. Jenni 4

A review of technical developments in electroplating during the year 1939. Joseph B. Kushner. *Metal Ind* (N. Y.) **38**, 20–1(1940).—Complete résumé of developments during 1939. 179 references. C. B. Jenni

Developments in electrotinning of strip steel. D. C. Bakewell. *Iron Steel Engr.* **16**, No. 12, 37–43(1939).—Present acid-bath practice has the following advantages over the alk. bath: (1) no heating is required for the bath; (2) a lower voltage may be used; (3) speed of deposition of Sn on the strip is more than double for the same cathode c. d. The desirable characteristics of the electrolyte are: (1) no sludge is formed owing to the oxidation of stannous salts to stannic form; (2) efficient operation at c. d. up to 300 amp./sq. ft.; (3) no polarization or passivity of the anodes during operation; (4) practically 100% anodic and cathodic efficiency even at high c. d. Operating procedure is described. C. B. Jenni 5 6

Electrodeposition of nickel from nickel chloride solutions. I. W. A. Wesley and J. W. Carey. *Products Finishing* **4**, No. 5, 9–12, 14, 16, 18, 20(1940); cf. *C. A.* **33**, 2813[6].—An address dealing with the historical development of the use of $NiCl_2$ as the principal ingredient of Ni-plating solns., soln. compn. of the chloride and sulfate baths, the plating range of the chloride bath and the characteristics of the deposits. Leopold Scheflan 7

Recent history of certain cobalt-nickel alloy plating solutions. Louis Weisberg. *Trans. Electrochem. Soc.* **77**, 6 pp. (preprint)(1940).—Developments in the com. electrodeposition of Co-Ni alloys during the past 2 years are described. Improvements in methods of removing impurities have made it possible to reduce the Co content of the deposit, for some purposes, as low as 1%. Substitution of Ni formate and formic acid for Na formate and 8 use of less NH_4 sulfate resulted in deposits that are more ductile and easier to buff than those formerly obtained. W. recommends: $NiSO_4$ 240 g./l., $NiCl_2$ 37, Ni formate 45, H_3BO_3 30, $CoSO_4$ 9, $(NH_4)_2SO_4$ 1.7, formaldehyde 1, pH 2–4 and temp. 65°. C. G. F.

A suggested basis for specifications of plated coatings of nickel and chromium. Arthur W. Hothersall. *Metal Ind.* (N. Y.) **38**, 27–30(1940).—See *C. A.* **34**, 1255[2]. C. B. Jenni 9

Chrome plating instead of nickel plating. N. P. Lapin. *Korroziya* **4**, No. 4, 306–8(1938); *Khim. Referat. Zhur.* **2**, No. 4, 142–3(1939).—A no. of expts. were performed with Cr plating using an electrolyte contg. HBF_4. The soln. contd. Cr_2O_3 400 g., $Cr(SO_4)_3$ 3 g., Zn dust 18 g., 50% soln. of HBF_4 2 cc., water 1 l. The soln. was very stable at low c. d. (1–3 amp./sq. dm.), a temp. of about 25° and with Pb anodes. This cold Cr bath, with an addn. of

a protective liquid, makes possible Cr plating under conditions close to those of Ni plating. W. R. Henn

Chromium plating of motor cylinders. Hendrik van der Horst. *Metal Ind.* (N. Y.) **38**, 76–8(1940).—A description of plating of large pistons and cylinders of Diesel engines and of application of a porous deposit of Cr which holds lubricating oil and which can be readily honed. C. B. Jenni

Overvoltage during the electrodeposition of mercury on tantalum. I. M. Malkin. *Ber. Inst. physik. Chem., Akad. Wiss. Ukr. S. S. R.* **11**, 109–19(1938); *Khim. Referat. Zhur.* **2**, No. 5, 14–15(1939); cf. *C. A.* **34**, 3284.—Overvoltage during the deposition of Hg on Ta electrode from satd. AcOH solns. of Hg_2O was investigated in water, in water with an addn. of 3% butyric acid, in satd. soln. of isoamyl alc. and in a 50% mixt. of water and CH_3OH. All solns. contained 1 *N* AcOH. Pt amalgam served as a control electrode. The cathodic c. d. varied between 10^{-6} and 10^{-4} amp./sq. cm. Ta was treated with HNO_3 before the measurements. The equil. potential varied between 0.1 and 0.3 v. An approx. linear relationship was found between the overvoltage η and the log of the c. d., *D*, with the angular coeff. varying from 0.09 (in the presence of butyric acid) to 0.37 (in the mixt. of water and CH_3OH). By linear extrapolation of the η-*D* curve the zero values of overvoltage were detd. They varied between 0.3 and 0.6 v. The preliminary treatment of the electrode surface greatly affected the overvoltage values. Anodic polarization increased the overvoltage considerably; cathodic polarization decreased it so that the deposition of Hg began at very low voltages. Evidently, the presence of the oxide film on the surface of the electrode hindered the deposition of Hg. No direct relationship was found between the overvoltage and the magnitude of the surface tension at the boundary, Hg-soln. W. R. H.

Construction of a dropping mercury electrode. B. A. Heller. *Ber. Inst. physik. Chem., Akad. Wiss. Ukr. S. S. R.* **11**, 131–4(1938); *Khim. Referat. Zhur.* **2**, No. 5, 13(1939).—Two types of Hg electrodes are described in which Hg does not come in contact with the rubber. This prevents its contamination as well as the contamination of the capillary. The change of pressure of the flowing Hg is obtained either by the immersion into Hg of the glass tube (increasing its level) or by means of a rising pressure ball. The Hg of the pressure ball is sepd. from the dropping Hg by an air interface. The dropping electrode can be used for a considerable time in both types without replacing the capillary. W. R. Henn

Plating on baby shoes. Andrew V. Re. *Metal Ind.* (N. Y.) **38**, 82–3(1940).—The method for plating on leather and other nonconducting surfaces is described. Information is given regarding cleaning and prepn. of the surface to make it conductive, and formulas of plating solns. are given. C. B. Jenni

The value of the microscope to the electroplater. B. Egeberg and N. E. Promisel. *Metal Ind.* (N. Y.) **37**, 255–8, 325–7, 355–7(1939).—The microscope is used to study thickness of plate, nature of basis metal, no. and nature of plates, alloying action of metals, color characteristics, and effectiveness of cleaning and dipping operations. Technique for mounting and polishing for microscopic study is fully discussed. Complete information is given for compn. of etching reagents for various metals and alloys. C. B. Jenni

The electrolytic etching of brass. G. C. Williams and G. Rieger. *Trans. Electrochem. Soc.* **77**, 4 pp.(preprint) (1940).—An easy and effective method of electrolytically etching brass specimens for metallographic examn. The procedure may be extended to numerous Cu alloys. The etching soln. is an ammoniacal NH_4 acetate, Na sulfite soln. The specimen is made anode at a c. d. of 31 amp./sq. dm. C. G. F.

Electrolytic stripping of copper from zinc-base die castings. W. B. Stoddard, Jr. *Trans. Electrochem. Soc.* **77**, 3 pp.(preprint)(1940).—Cu can be stripped from Zn-base die castings in a Cr plating soln. with 50–60 cycle a. c., CrO_3 200–500 g./l., ratio CrO_3:SO_4 100:1, temp. 20°–25°, c. d. 7–14 amp./sq. dm. After stripping, the Zn surface is activated by dipping the articles into cold, dil. HCl (10 cc./l. of HCl, sp. gr. 1.19). C. G. F.

Bleaching-liquor by electrolytic process. N. A. Ranade. *Indian Textile J.* **50**, 119(1940).—The standard electrolyzer of 17–23 plates is designed for 100–110 v. A 5–15% NaCl soln. is electrolyzed with graphite or Pt electrodes at temp. limits of 22–32°. With proper precautions 11 g. of available Cl per l. is obtained. The NaClO soln. is tested for strength by titration with 0.1 *N* $Na_2S_2O_3$ soln. W. H. Boynton

Anodic polishing of metals. Carl Schaefer. *Metal Ind.* (N. Y.) **38**, 22–6(1940).—Anodic polishing is essentially an electrolytic pickling process and is best suited for pure metals or alloys of homogeneous structures. The high c. ds. used necessitate special care in racking. Methods for anodic polishing of Cu, brass, bronze, Al, iron and steel, Sn, Pb, Ni, Zn and Co are given with proper etching solns. and procedures. A mechanism for the anodic etching process is suggested. Thirteen references. C. B. Jenni

Anodic coating of aluminum. Junius D. Edwards. *Metal Ind.* (N. Y.) **38**, 513–19, 522(1939).—See *C. A.* **33**, 7207[1]. C. B. Jenni

Anodic treatment of aluminum. Survey of modern practice. Henry A. Smith. *Metal Ind.* (London) **56**, 113–15(1940).—See *C. A.* **34**, 1256[2]. A. D.

Anodic finishes for sheet aluminum products. E. G. West. *Sheet Metal Ind.* **13**, 1259–61(1939).—A review. Iver Igelsrud

Electrolytic oxidation of white ferrous ferrocyanide in the production of Prussian blue. E. F. Belen'kiĭ and M. K. Vorontsov. *Org. Chem. Ind.* (U. S. S. R.) **6**, 313–17 (1939).—A modification of the method of Stender and Semenov (*C. A.* **28**, 3667[3]) is discussed. Chas. Blanc

The protection of silver by the electrolytic deposition of beryllia. L. E. Price and G. J. Thomas. *Metal Ind.* (N. Y.) **37**, 507–10(1939).—See *C. A.* **33**, 9151[8]. C. B. Jenni

Overvoltage of hydrogen in water-alcohol and ether-alcohol mixtures. I. S. Novosel'skiĭ. *Ber. Inst. physik. Chem., Akad. Wiss. Ukr. S. S. R.* **11**, 125–9(1938); *Khim. Referat. Zhur.* **2**, No. 5, 14(1939); cf. *C. A.* **33**, 4136[1].—The overvoltage of H_2 on Hg in acid solns., in mixts. of water and EtOH (0–100% EtOH) and of EtOH and Et_2O [0.56% of Et_2O] were investigated. For all mixts. the dependence of the overvoltage on the c. d. (10^{-2}–10^{-2} amp./sq. cm.) obeys Tafel's equation. The value of the angle coeff. was 0.11–0.12. An addn. of water or of ether to alc. caused a lowering of the overvoltage. Its max. value occurred upon the addn. of small amts. (1–3%) of the 2nd component. The magnitude of this effect was about 70 mv. W. R. Henn

Nitration of benzene by oxides of nitrogen in the glow discharge. D. Avanesov and I. Vyatskin. *Trudy LKKhTI* **1939**, No. 7, 60–4; *Khim. Referat. Zhur.* **2**, No. 5, 43(1939).—Nitration of vapors of C_6H_6 was performed by gaseous N_2O_4 in a glow discharge in a Siemens type of tube. Rate of flow of the gases and intensity of discharge could be regulated at will. The products of the reaction comprised: nitrobenzene, *m*-dinitro- and trinitrophenols. W. R. Henn

The electrochemical oxidation of 1-hexanol. Wm. R. Lowstuter and Alexander Lowy. *Trans. Electrochem. Soc.* **77**, 8 pp.(preprint)(1940).—1-Hexanol was oxidized electrochemically, giving caproic acid and hexyl caproate. Besides these main products, small amts. of CO_2, CO and a high-boiling residue were obtained. Hexaldehyde and decane were not found to be present in the products of the electrolysis. A study was made of the various factors influencing the oxidation, such as anode material, temp., c. d., solvent and alc. concn. of the anolyte for the electrolytic oxidation of 1-hexanol. The best results were obtained with: (*a*) 5% H_2SO_4 as electrolyte; (*b*) c. d., 1.1 amp./sq. dm.; (*c*) temp. 12°; (*d*) electrolytically prepd. PbO_2 anode; (*e*) anolyte concn., 82 g. 1-hexanol in 800 cc. of electrolyte; current efficiency, 59.9% calcd. only as oxidation to caproic acid. C. G. F.

Selenium rectifier for electrolysis. S. Sinkai and T.

Nakagawa. *J. Soc. Chem. Ind. Japan* **42**, Suppl. binding 396–7(1939).—A hook-up is described for rectification of an a. c. for use in the electroanalysis of Cu. Results using the rectified current and d. c. from a battery are identical. George Ayers

Arcs—their operation and light output. W. E. Forsythe. *Illum. Eng.* **35**, 127–41(1940).—An exhaustive review with 15 illustrations. Main stress is laid on the C and the Hg arcs for illuminating purposes. C. G. F.

The photoelectric cell. C. L. Wrenshall. *Pulp Paper Mag. Can.* **40**, 685–7(1939).—An explanation of the principle of its operation, with examples of its use in industry. A. Papineau-Couture

Apply thin, uniform ground coats by electric deposition. A. E. Badger and Burnham W. King, Jr. *Ceram. Ind.* **34**, 41(Feb., 1940).—A preliminary expt. shows the possibility of applying enamel compn. to Fe by means of electrophoresis. A series of samples so prepd. is shown. Herbert S. Willson

Progress in engineering knowledge during 1939. P. L. Alger. *Gen. Elec. Rev.* **43**, 60–88(1940).—An annual review, with chapters on electron emission, gaseous dielectrics, lamps, luminescence, metallurgy, proteins, radiation, welding, etc. C. G. F.

Plating and Finishing Guidebook (formerly Platers' Guidebook). 8th ed. Edited by **Walter R. Meyer**. New York: Metal Industry Publishing Co. 92 pp.

Storage battery. Leland R. Adams. U. S. 2,184,373, Dec. 26. Various details of a battery having porous insulation such as a rubber compn. molded around and extending between the plates.

Apparatus for supplying electrolyte to electrolytic cells such as alkali chloride cells. Kenneth E. Stuart (to Hooker Electrochemical Co.). U. S. 2,183,299, Dec. 12. Various structural and operative details.

Electrolytic condenser. Preston Robinson and Joseph L. Collins (to Sprague Specialties Co.). U. S. 2,183,776, Dec. 19. Various details of a condenser comprising an electrolyte such as one contg. Na or NH_4 borate in which is immersed an Al electrode carrying a layer of substantially unhydrated Al oxide and an adjacent layer of hydrated Al oxide.

Electrodeposition of nickel. Eugene D. Viers and Bernard C. Case (to Eaton Mfg. Co.). U. S. 2,183,384, Dec. 12. A sol. anode for the electrodeposition of Ni from an acid bath comprises a relatively large percentage of Ni together with another metal such as Co 0.69–3.0, Cd 0.37–1.6, Pb 0.1–0.7, Zn 0.22–1.21 or Sn 0.15–0.9%, and its use produces a pit-free gray plate with a thickness over 0.0006 in. and having a grain size above that of bright Ni, but below that at which pitting, due to grain size, occurs.

Coating light metals. Magnesium Elektron Ltd. Brit. 508,723, July 5, 1939. Compact, adherent fluoride coatings of uniform thickness are produced on Mg, Al and Mg or Al alloys by anodic treatment, without the application of heat, a satd. or almost satd. aq. soln. of a single neutral fluoride or fluosilicate the soly. of which in H_2O is at least about 30% at 20° being used as electrolyte; or a satd. aq. soln. of a mixt. of neutral fluorides and (or) fluosilicate, the soly. of which mixt. is at least about 30% at 20° may be used. Specified compds. are KF, NH_4F, mixts. or double salts of ZnF_2 with alkali metal (including NH_4) fluorides, $MgSiF_6$ and (or) $ZnSiF_6$. Voltages that maintain a c. d. of 2 amp. per sq. dcm. are preferred.

Melting magnesium and magnesium base alloys. Magnesium Elektron Ltd. Brit. 508,670, July 4, 1939. In melting Mg, etc., in an induction furnace originally provided with a siliceous lining consisting of pure oxides such as Al_2O_3 or MgO mixed with SiO_2, reaction of Mg with the SiO_2 is avoided by subjecting the portions of the lining that are liable to come into contact with the molten metal to a treatment with molten Al or Al-base alloy to remove SiO_2 therefrom and thereafter melting the Mg, etc., in the thus conditioned furnace. The melting of the Al or Al base alloy may be effected by induction heating.

Persulfuric acid. Robert C. Cooper, Oswald H. Walters and Imperial Chemical Industries Ltd. Brit. 508,524, July 3, 1939. $H_2S_2O_8$ or a persulfate is manufd. by electrolysis of aq. H_2SO_4 or of a soln. of a sulfate, the anodic oxidation being performed in a cell in which the anode compartment consists of a trough long in comparison with its width and having at least 1 of its sides formed of a porous diaphragm on the other side of which is a cathode compartment, means being provided for introducing anolyte to 1 end of the trough and for withdrawing it from the other end. Preferably also, catholyte is continuously or intermittently withdrawn from the cell, cooled and returned to the cathode compartment after adjustment of its acidity by an appropriate addn. of H_2SO_4 or of a bisulfate.

Electrothermal decomposition of carbonaceous liquids. E. I. du Pont de Nemours & Co. Brit. 508,509, June 30, 1939. *C black* is manufd. by establishing an elec. arc beneath the surface of the liquid, the concn. of the gaseous decompn. products being increased in the vicinity of the submerged arc. The liquid may be agitated and the gaseous decompn. products partially confined, e. g., by a baffle means, in the vicinity of the arc. The liquid may have suspended therein about 5–12% C black. Cf. *C. A.* **33**, 9159[9].

Low-power electric heating element. Etienne Challet (25% to Entreprises electriques Fribourgeoises). U. S. 2,184,485, Dec. 26. An elec. resistance is embedded immediately below the upper surface of a flat flexible cushion made of glass wool and a substantial portion of the resistance is covered with a layer of nonfibrous glass fused to the glass wool.

Electrical conductors such as wires, etc. Horace F. Silliman (to American Brass Co.). U. S. 2,183,592, Dec. 19. Use is made of Cu alloyed with B 0.01–0.15%, which serves to avoid embrittlement when heated in a reducing atm.

Purifying carbonaceous wastes from electric-furnace production of aluminum. Bruce D. Crawford (to American Cyanamid Co.). U. S. 2,183,500, Dec. 12. A method of purification of carbonaceous furnace waste from the elec.-furnace production of Al contg. as its major constituents C, Al_2O_3 and cryolite (the C and cryolite being present in about the same proportion) involves grinding the waste to at least 50% through 200 mesh, forming an aq. pulp of the finely ground material and subjecting the pulp to froth flotation and removing the froth rich in C and poor in cryolite.

Cathode activation and degassing. Hans J. Spanner. U. S. 2,184,323, Dec. 26. A process for producing elec. discharge lamps with arc-heated electrodes by which the electrode carrier metal is provided with a coating of an alk. earth metal oxide, and alk. earth metal is produced by reduction of the oxide, is characterized by the fact that the electrode provided with the alk. earth metal oxide is heated in a sep. auxiliary vessel under a high vacuum until a thorough degassing of the electrode and reduction of the alk. earth metal oxide occurs whereupon the auxillary vessel is removed from around the electrode and the electrode is then first built into the lamp vessel.

Thermonegative resistors. Walter Schottky (to Siemens & Halske A.-G.). U. S. 2,183,755, Dec. 19. A resistor with a descending characteristic may comprise a wire- or ribbon-like α-conductor of material such as CuO

or UO_2 embedded in a refractory insulating material (various structural and mfg. details being described). 1

Apparatus and method for determining the dielectric constants of electrically conductive solutions. Raardt & Co. A.-G. Brit. 508,783, July 3, 1939. Use is not made of a bridge circuit but of a single high-frequency oscillatory measuring circuit comprising 1 condenser in which the soln. is placed and another in parallel thereto, the latter in general being variable for the purpose of measurement, and to overcome the damping effect on the oscillations owing 2 to cond. of the soln. an impedance unit comprising capacity or inductance or resistance alone or in combination is connected in series with the measuring condenser in such a way that the variable condenser is in parallel across both the measuring condenser and the series impedance, the latter being of such value that the undamped oscillation necessary for the measurement remains maintained. The app. and method are adapted for the detn. of the dielec. coeff. 3 of humus-contg. earth, for tests into the decompn. of cement, for detn. of the content of waste H_2O in org. mixts. and for concn. detns. and measurement of changes in blood serum, moist alkali-cellulose, the elimination of $ZnCl_2$ in the manuf. of vulcanized fiber, the moisture content of butter, margarin, cheese, etc.

High-resistance wall coatings for vacuum tubes. Gerhard Brauer (to Fernseh A.-G.). U. S. 2,183,302, Dec. 12. A metallic gaseous carbonyl such as that of Ni is 4 introduced into an evacuated tube and the wall of the tube is heated to cause deposition of metal from the carbonyl, the tube is re-evacuated, and the metallic coating formed is oxidized, as by use of O at 400°.

Photoelectric cell. Kurt Gäbler (to Zeiss Ikon A.-G.). U. S. 2,183,256, Dec. 12. A base is provided with a light-sensitive layer having applied on its outer surface a coating of lacquer and protected from tropical atm. conditions by a layer of hydrated cellulose on top of the lacquer coating and a cover layer of transparent synthetic resin on top of the cellulose layer and extending around the edges of the superposed layers.

Luminescent tube suitable for use with a high frequency electric field. Harold D. Penney and Wm. Weis. U. S. 2,184,530, Dec. 26. Various structural details.

Electric discharge tubes utilizing secondary emission. N. V. Philips' Gloeilampenfabrieken. Brit. 508,778, July 5, 1939. Tubes comprising an electrode system including at least 1 secondary-emission electrode arranged out of sight of the primary cathode have the secondary emission electrode, particularly when coated with 1 or more oxides of alkali or alk. earth metals, provided with means for the cooling thereof, e. g., cooling ribs or a coating of black material.

Process and apparatus for hermetically closing vessels, especially electric incandescent lamps, containing gases at greater than atmospheric pressures. Egyesült Izzólámpa és Villamossági R. T. Brit. 508,615, July 4, 1939.

Treating wires such as those of nickel for use in incandescent electric lamps. John H. Ramage (to Westinghouse Elec. & Mfg. Co.). U. S. 2,183,972, Dec. 19. A 4 wire of metal such as Ni is heated to an elevated temp. (suitably about 760–1100°) in flowing H and, while still heated, is subjected to flowing N to replace the H absorbed, and is then cooled in N. App. is described.

5—PHOTOGRAPHY

E. R. BULLOCK

Photography with luminiferous materials: some experiments towards a new process. T. F. Langlands. *Brit. J. Phot.* **86**, 246–8(1939).– A luminous image can be produced on a luminescent material in a camera with moderate exposures. L. suggests the use of such records in an elec. picture-transmitting app. to avoid the use of ordinary photographic processing. E. W. H. Selwyn 6

Photography with luminiferous materials. M. J. Brown. *Brit. J. Phot.* **86**, 352(1939); cf. Langlands, preceding abstr.—Some materials that are luminescent in white light have this luminescence quenched by red light. With such materials it is not difficult to project images which are negatives of the picture projected. E. W. H. Selwyn

Reversal processes. H. Mills Cartwright. *Process Engraver's Monthly* **46**, 273(1939).—The possibility of a 7 reduction in the no. of operations in photogravure technique by using a reversal process to produce a direct positive is discussed. R. F. W. Selman

The adsorption theory of development. Lüppo-Cramer. *Phot. Korr.* **75**, 97–103(1939); cf. *C. A.* **33**, 9164⁹.—In a continuation of his investigations on the adsorption theory of development, L.-C. considers the action of adsorbed foreign substances in causing isolation of the nuclei (and 8 thus acceleration of development) or isolation of the grains themselves (fog). The latter is seen with an aerially oxidizing hydroquinone developer. When used as a preliminary bath, however, a 0.1% neutral distd. aq. soln. of hydroquinone which has been allowed to stand for 1 hr. (and is still, although oxidized considerably, not colored) reduces the latent image without producing fog. In the latter case, the hydroquinone is, as far as oxidized at all, converted to quinone, whereas with the developer its oxidation products are the so-called humic acids. L.-C. shows that while, as a rule, development is restrained by acid, and accelerated by basic, dyes, the specific nature of the dye is important. L.-C., finally, reviews certain previously published results in the light of the above-mentioned theoretical considerations. E. R. Bullock

Mechanism of formation and development of a latent photographic image. P. D. Dankov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 773–8(1939)(in English).—"In this study an attempt is made to analyze more thoroughly the mechanism of the formation and development of the latent photographic image. For this purpose it has been found necessary to take into account the principle of orientation and dimensional conformity, suggested by Dankov (*C. A.* **33**, 8160⁸), of the processes which develop at the boundary of 2 phases. At the same time the proposed scheme contains the idea of the electrocrystn. nature of the metal's pptn. during reduction processes (*Compt. rend. acad. sci. U. R. S. S.* **24**, 886–90(1939)(in English))." It is shown that the spacing of the Ag ions in the lattice of AgBr is, as regards 1 plane, almost exactly identical with the spacing of the Ag atoms in metallic Ag. In a direction normal to this plane, however, a shortening of the distances between atoms by about 29% (i. e., from 5.76 to 4.077 A.) would be necessary for the conversion of the Ag to the full metallic state. D. suggests that an aggregate of Ag atoms at the "transitional stage" when the Br has escaped but before the Ag atoms have moved from the position of the original Ag ions may constitute the latent image. These considerations do not apply as successfully to AgCl, since, in that case, the edge of the cube (5.54 A.) is 3.8% less than the diagonal in the Ag lattice (5.76 A.). In development, "(1) at the boundary metal/halide, electrons of the metal pass to the ions which are being reduced and (2) electrons pass from the reducer to the metal all along the free metal surface." D. shows that explanations of the Herschel and Weigert effects follow as corollaries of the theory suggested, which, moreover, can be applied to the general phenomena of transformations in solids under the influence of radiation. E. R. Bullock

"Divided" [two-bath] development—revised formula. C. H. Shipman. *Photography* **7**, No. 83, 15(1939).—A 2-bath system of development which gives full shadow detail and guards against excessive highlight d. uses a soln. (*A*) contg. developing agents, followed by an accelerator soln. (*B*) or (*C*). *A:* metol 95, Na_2SO_3 500, hydroquinone 95, KBr 40, NaCl 3 grains and H_2O 32 oz.; *B:* Na_2CO_3 1500 grains and H_2O 32 oz.; *C:* borax 800 grains and H_2O 32 oz. T. L. J. Bentley

Nakagawa. *J. Soc. Chem. Ind. Japan* **42**, Suppl. binding 396–7(1939).—A hook-up is described for rectification of an a. c. for use in the electroanalysis of Cu. Results using the rectified current and d. c. from a battery are identical. George Ayers

Arcs—their operation and light output. W. E. Forsythe. *Illum. Eng.* **35**, 127–41(1940).—An exhaustive review with 15 illustrations. Main stress is laid on the C and the Hg arcs for illuminating purposes. C. G. F.

The photoelectric cell. C. L. Wrenshall. *Pulp Paper Mag. Can.* **40**, 685–7(1939).—An explanation of the principle of its operation, with examples of its use in industry. A. Papineau-Couture

Plating and Finishing Guidebook (formerly Platers' Guidebook). 8th ed. Edited by **Walter R. Meyer**. New York: Metal Industry Publishing Co. 92 pp.

Storage battery. Leland R. Adams. U. S. 2,184,373, Dec. 26. Various details of a battery having porous insulation such as a rubber compn. molded around and extending between the plates.

Apparatus for supplying electrolyte to electrolytic cells such as alkali chloride cells. Kenneth E. Stuart (to Hooker Electrochemical Co.). U. S. 2,183,299, Dec. 12. Various structural and operative details.

Electrolytic condenser. Preston Robinson and Joseph L. Collins (to Sprague Specialties Co.). U. S. 2,183,776, Dec. 19. Various details of a condenser comprising an electrolyte such as one contg. Na or NH_4 borate in which is immersed an Al electrode carrying a layer of substantially unhydrated Al oxide and an adjacent layer of hydrated Al oxide.

Electrodeposition of nickel. Eugene D. Viers and Bernard C. Case (to Eaton Mfg. Co.). U. S. 2,183,384, Dec. 12. A sol. anode for the electrodeposition of Ni from an acid bath comprises a relatively large percentage of Ni together with another metal such as Co 0.69–3.0, Cd 0.37–1.6, Pb 0.1–0.7, Zn 0.22–1.21 or Sn 0.15–0.9%, and its use produces a pit-free gray plate with a thickness over 0.0006 in. and having a grain size above that of bright Ni, but below that at which pitting, due to grain size, occurs.

Coating light metals. Magnesium Elektron Ltd. Brit. 508,723, July 5, 1939. Compact, adherent fluoride coatings of uniform thickness are produced on Mg, Al and Mg or Al alloys by anodic treatment, without the application of heat, a satd. or almost satd. aq. soln. of a single neutral fluoride or fluosilicate the soly. of which in H_2O is at least about 30% at 20° being used as electrolyte; or a satd. aq. soln. of a mixt. of neutral fluorides and (or) fluosilicate, the soly. of which mixt. is at least about 30% at 20° may be used. Specified compds. are KF, NH_4F, mixts. or double salts of ZnF_2 with alkali metal (including NH_4) fluorides, $MgSiF_6$ and (or) $ZnSiF_6$. Voltages that maintain a c. d. of 2 amp. per sq. dcm. are preferred.

Melting magnesium and magnesium base alloys. Magnesium Elektron Ltd. Brit. 508,670, July 4, 1939. In melting Mg, etc., in an induction furnace originally provided with a siliceous lining consisting of pure oxides such as Al_2O_3 or MgO mixed with SiO_2, reaction of Mg with the SiO_2 is avoided by subjecting the portions of the lining that are liable to come into contact with the molten metal to a treatment with molten Al or Al-base alloy to remove SiO_2 therefrom and thereafter melting the Mg, etc., in the thus conditioned furnace. The melting of the Al or Al base alloy may be effected by induction heating.

Persulfuric acid. Robert C. Cooper, Oswald H. Walters and Imperial Chemical Industries Ltd. Brit. 508,524, July 3, 1939. $H_2S_2O_8$ or a persulfate is manufd. by electrolysis of aq. H_2SO_4 or of a soln. of a sulfate, the anodic oxidation being performed in a cell in which the anode compartment consists of a trough long in comparison with its width and having at least 1 of its sides formed of a porous diaphragm on the other side of which is a cathode compartment, means being provided for introducing anolyte to 1 end of the trough and for withdrawing it from the other end. Preferably also, catholyte is continuously or intermittently withdrawn from the cell, cooled and returned to the cathode compartment after adjustment of its acidity by an appropriate addn. of H_2SO_4 or of a bisulfate.

Electrothermal decomposition of carbonaceous liquids. E. I. du Pont de Nemours & Co. Brit. 508,509, June 30, 1939. *C black* is manufd. by establishing an elec. arc beneath the surface of the liquid, the concn. of the gaseous decompn. products being increased in the vicinity of the submerged arc. The liquid may be agitated and the gaseous decompn. products partially confined, e. g., by a baffle means, in the vicinity of the arc. The liquid may have suspended therein about 5–12% C black. Cf. *C. A.* **33**, 9159[9].

Low-power electric heating element. Etienne Challet (25% to Entreprises electriques Fribourgeoises). U. S. 2,184,485, Dec. 26. An elec. resistance is embedded immediately below the upper surface of a flat flexible cushion made of glass wool and a substantial portion of the resistance is covered with a layer of nonfibrous glass fused to the glass wool.

Electrical conductors such as wires, etc. Horace F. Silliman (to American Brass Co.). U. S. 2,183,592, Dec. 19. Use is made of Cu alloyed with B 0.01–0.15%, which serves to avoid embrittlement when heated in a reducing atm.

Purifying carbonaceous wastes from electric-furnace production of aluminum. Bruce D. Crawford (to American Cyanamid Co.). U. S. 2,183,500, Dec. 12. A method of purification of carbonaceous furnace waste from the elec.-furnace production of Al contg. as its major constituents C, Al_2O_3 and cryolite (the C and cryolite being present in about the same proportion) involves grinding the waste to at least 50% through 200 mesh, forming an aq. pulp of the finely ground material and subjecting the pulp to froth flotation and removing the froth rich in C and poor in cryolite.

Cathode activation and degassing. Hans J. Spanner. U. S. 2,184,323, Dec. 26. A process for producing elec. discharge lamps with arc-heated electrodes by which the electrode carrier metal is provided with a coating of an alk. earth metal oxide, and alk. earth metal is produced by reduction of the oxide, is characterized by the fact that the electrode provided with the alk. earth metal oxide is heated in a sep. auxiliary vessel under a high vacuum until a thorough degassing of the electrode and reduction of the alk. earth metal oxide occurs whereupon the auxillary vessel is removed from around the electrode and the electrode is then first built into the lamp vessel.

Thermonegative resistors. Walter Schottky (to Siemens & Halske A.-G.). U. S. 2,183,755, Dec. 19. A resistor with a descending characteristic may comprise a wire- or ribbon-like α-conductor of material such as CuO

or UO_3 embedded in a refractory insulating material (various structural and mfg. details being described). 1

Apparatus and method for determining the dielectric constants of electrically conductive solutions. Raardt & Co. A.-G. Brit. 508,783, July 3, 1939. Use is not made of a bridge circuit but of a single high-frequency oscillatory measuring circuit comprising 1 condenser in which the soln. is placed and another in parallel thereto, the latter in general being variable for the purpose of measurement, and to overcome the damping effect on the oscillations owing to cond. of the soln. an impedance unit comprising capacity or inductance or resistance alone or in combination is connected in series with the measuring condenser in such a way that the variable condenser is in parallel across both the measuring condenser and the series impedance, the latter being of such value that the undamped oscillation necessary for the measurement remains maintained. The app. and method are adapted for the detn. of the dielec. coeff. of humus-contg. earth, for tests into the decompn. of cement, for detn. of the content of waste H_2O in org. mixts. and for concn. detns. and measurement of changes in blood serum, moist alkali-cellulose, the elimination of $ZnCl_2$ in the manuf. of vulcanized fiber, the moisture content of butter, margarin, cheese, etc. 2 3

High-resistance wall coatings for vacuum tubes. Gerhard Brauer (to Fernseh A.-G.). U. S. 2,183,302, Dec. 12. A metallic gaseous carbonyl such as that of Ni is introduced into an evacuated tube and the wall of the tube is heated to cause deposition of metal from the carbonyl, the tube is re-evacuated, and the metallic coating formed is oxidized, as by use of O at 400°. 4

Photoelectric cell. Kurt Gäbler (to Zeiss Ikon A.-G.). U. S. 2,183,256, Dec. 12. A base is provided with a light-sensitive layer having applied on its outer surface a coating of lacquer and protected from tropical atm. conditions by a layer of hydrated cellulose on top of the lacquer coating and a cover layer of transparent synthetic resin on top of the cellulose layer and extending around the edges of the superposed layers.

Luminescent tube suitable for use with a high frequency electric field. Harold D. Penney and Wm. Weis. U. S. 2,184,530, Dec. 26. Various structural details.

Electric discharge tubes utilizing secondary emission. N. V. Philips' Gloeilampenfabrieken. Brit. 508,778, July 5, 1939. Tubes comprising an electrode system including at least 1 secondary-emission electrode arranged out of sight of the primary cathode have the secondary emission electrode, particularly when coated with 1 or more oxides of alkali or alk. earth metals, provided with means for the cooling thereof, e. g., cooling ribs or a coating of black material.

Process and apparatus for hermetically closing vessels, especially electric incandescent lamps, containing gases at greater than atmospheric pressures. Egyesült Izzólámpa és Villamossági R. T. Brit. 508,615, July 4, 1939.

Treating wires such as those of nickel for use in incandescent electric lamps. John H. Ramage (to Westinghouse Elec. & Mfg. Co.). U. S. 2,183,972, Dec. 19. A wire of metal such as Ni is heated to an elevated temp. (suitably about 760–1100°) in flowing H and, while still heated, is subjected to flowing N to replace the H absorbed, and is then cooled in N. App. is described.

For this purpose it has been found necessary to take into account the principle of orientation and dimensional conformity, suggested by Dankov (*C. A.* **33**, 8160⁶), of the processes which develop at the boundary of 2 phases. At the same time the proposed scheme contains the idea of the electrocrystn. nature of the metal's pptn. during reduction processes (*Compt. rend. acad. sci. U. R. S. S.* **24**, 886–90(1939)(in English))." It is shown that the spacing of the Ag ions in the lattice of AgBr is, as regards 1 plane, almost exactly identical with the spacing of the Ag atoms in metallic Ag. In a direction normal to this plane, however, a shortening of the distances between atoms by about 29% (i. e., from 5.76 to 4.077 A.) would be necessary for the conversion of the Ag to the full metallic state. D. suggests that an aggregate of Ag atoms at the "transitional stage" when the Br has escaped but before the Ag atoms have moved from the position of the original Ag ions may constitute the latent image. These considerations do not apply as successfully to AgCl, since, in that case, the edge of the cube (5.54 A.) is 3.8% less than the diagonal in the Ag lattice (5.76 A.). In development, "(1) at the boundary metal/halide, electrons of the metal pass to the ions which are being reduced and (2) electrons pass from the reducer to the metal all along the free metal surface." D. shows that explanations of the Herschel and Weigert effects follow as corollaries of the theory suggested, which, moreover, can be applied to the general phenomena of transformations in solids under the influence of radiation. E. R. Bullock 5 6 7 8

"Divided" [two-bath] development—revised formula. C. H. Shipman. *Photography* **7**, No. 83, 15(1939).—A 2-bath system of development which gives full shadow detail and guards against excessive highlight d. uses a soln. (*A*) contg. developing agents, followed by an accelerator soln. (*B*) or (*C*). *A:* metol 95, Na_2SO_3 500, hydroquinone 95, KBr 40, NaCl 3 grains and H_2O 32 oz.; *B:* Na_2CO_3 1500 grains and H_2O 32 oz.; *C:* borax 800 grains and H_2O 32 oz. T. L. J. Bentley 9

Fog-producing fluorescence of pyro developers. W. A. Benton. *Brit. J. Phot.* **86**, 223–4(1939). H. H. Goodchild, H. W. Greenwood and O. F. Bloch. *Ibid.* 239–40; J. H. Coote. *Ibid.* 256.—Observations are described of a chemiluminescence on the aerial oxidation of developers contg. pyrogallol. The luminescence was sufficient to fog panchromatic plates. A. Marriage

Fatal poisoning from photographic developer containing hydroquinone. Santo Busatto. *Deut. Z. ges. gerichtl. Med.* **31**, 285–97(1939).—Fatal poisoning in man is unknown. Experimentally, hydroquinone is rapidly decompd. by the organism but pathol. changes may be produced in the parenchymatous tissue of the liver and kidney. Frances Krasnow

Permanence of Agfacolor. W. H. D. Yule. *Brit. J. Phot.* **86**, 663–4(1939).—To test the permanence of (triple-layer) Agfacolor transparencies under exposure to atm. conditions strips of film were loosely mounted in a partially bound-up glass sandwich which was left outdoors from Nov. to Feb. in a position in which it was protected only from direct rain. Marked fading was shown to occur except where the film was masked by black tape, but the color rendering was not seriously falsified. Fading of the masked portion was only detectable by direct comparison with a control. The blue component showed most fading, but the behavior of the red component was not tested by the sample selected. T. L. J. Bentley

Tone rendering by transparent screen negatives and positives. F. J. Tritton and E. T. Wilson. *Phot. J.* **79**, 396–406, 412(1939).—The theoretically ideal curves of screen positive and negative for halftone reproduction of a continuous-tone original are derived and their relation to present-day practice is discussed. An attempt is described to prep. a screen negative and positive that when used in combination will show accurate tone rendering of the original. R. F. W. Selman

Toning and intensification with dithioöxamide. G. Nilsson. *Brit. J. Phot.* **86**, 329–30(1939); cf. *C. A.* **33**, 6755[3].—Methods of toning or intensifying are described in which a Ag image is converted to one of the Cu, Ni or Co salts of dithioöxamide (rubeanic acid). The Ag image is 1st treated with a bath contg. a ferricyanide, a salt of 1 of the above metals and a citrate. The ferrocyanide of the metal thus obtained is treated with an alk. soln. of dithiooxamide. The Cu salt then gives a strong dark-green image (useful for toning or intensification), the Ni salt, a bluish-violet tone, and the Co, a brownish-yellow tone. Details of solns. required are given. A. Marriage

Photochemistry of azides of heavy metals. S. M. Moskovich. *Ber. Inst. physik. Chem., Akad. Wiss. Ukr. S. S. R.* **9**, 77–86(in Russian, 86–7; in German, 87–8)(1938).—See *C. A.* **33**, 4892[3]. B. Z. Kamich

Amidol for miniature films. David Charles. *Amateur Photographer* **88**, 445(1939).—To test the suitability of amidol, with miniature films, as a developer conveniently made up from dry constituents when traveling, contrasty subjects were given minimum exposures and developed in the following soln.: Na_2SO_3 60, amidol 15, KBr 3 grains and H_2O 20 oz. Prints of satisfactory contrast were obtained and a 25 times enlargement from a high-speed film showed little graininess. M. D. G.

The recovery of silver from acid fixing baths. G. R. Namias. *Il progresso foto.* **46**, 272–4(1939); *Brit. J. Phot.* **86**, 667.—In a review of chem. and elec. methods of recovering Ag from acid fixing baths, the use of Cu, Fe carbonyl powder and other precipitants is considered. The influence of electrode material and c. d. upon the electrolytically obtained deposit is discussed. M. D. G.

Increase of sensitivity of photographic plates by treatment with mercury vapor. D. V. Pyaskovskiĭ. *Astron. J. Soviet Union* **16**, No. 3, 75–80(1939).—Plates prepd. from emulsions treated with Hg vapor attain their max. sensitivity (about 2.8 times that of an untreated plate) within 1 day; after that the sensitivity decreases, and after 1 month is the same as that of untreated plates. The fog increases very slightly, while spectral sensitivity and contrast remain unchanged. Data are given for various Soviet and German ortho-, iso- and pan-chromatic plates. F. H. Rathmann

Industrial x-ray negatives, prints and transparencies. G. W. C. Taylor. *Brit. J. Phot.* **86**, 388–9(1939).—Advice is given in making industrial x-ray radiographs. W. F. Berg

Home processing of cine[matograph] film. Percy W. Harris. *Phot. J.* **79**, 139–43(1939).—Practical hints for processing motion picture films in the home by the neg.-pos. process and by reversal. E. D. Eyles

Photographer's dermatitis and its treatment. U. F. Alstead. *Photography* **7**, No. 83, 23(1939).—Discussion. T. L. J. Bentley

Color photography. Béla Gáspár. U. S. 2,183,393, Dec. 12. Various details are given of the manuf. and use of a light-sensitive material for producing multicolor images comprising a transparent support and three light-sensitive Ag halide layers, the two outer layers being of the same predominant sensitivity, the middle layer being predominantly sensitive for another part of the spectrum, each of the outer layers allowing transmission of the light rays for which the layer is sensitized, and at least one of the outer layers being insensitive to and allowing transmission of light rays for which the middle layer is sensitized, the middle layer being colored by a dye which is not removable by ordinary photographic treating baths but which is selectively removable under the influence of the Ag image and which transmits light rays for which the layer itself is sensitized but absorbs the light rays for which both the outer films are sensitized. U. S. 2,183,394 relates to a method of producing a subtractive multicolor picture from a multilayer light-sensitive Ag halide material, having on a common support a colorless surface layer of Ag halide emulsion and a differently sensitized Ag halide layer which is uniformly pre-dyed by a reducible dye resistant to the ordinary photographic treating solns. but capable of being locally destroyed under the control of a metallic Ag image, which comprises exposing each of the layers to light to form latent images in the Ag halide layers, developing the latent images to form Ag images, coloring the colorless surface layer uniformly with a reducible dye which transmits blue light and thereafter destroying the dye in the surface layer and the pre-dyed layer at the points of metallic Ag. U. S. 2,183,395 relates to use of a light-sensitive multilayer material comprising several Ag halide emulsion layers on a common support, one Ag halide layer contg. both a dye that is resistant to ordinary developers but capable of being locally bleached by reduction in the presence of a metallic Ag image, and a catalyst for dye reduction, at least one other layer comprising a dye of different shade and of a higher inherent bleaching speed, the amt. of catalyst being such as to render the

bleaching speed of the first dye substantially equal to that of the other dye.

Color photography. Merrill W. Seymour (to Eastman Kodak Co.). U. S. 2,184,022, Dec. 19. A process of producing a colored photographic image in a gelatin layer involves forming a Ag image in a gelatin layer contg. a vat dye and bleaching the dye in an alk. $SnCl_2$ soln. in the region of the Ag image, and removing the Ag from the layer. Triethanolamine may be used with the $SnCl_2$.

Color photography. Andrew B. Jennings and Edmund B. Middleton (to Du Pont Film Mfg. Corp.). U. S. 2,184,303, Dec. 26. A color-forming photographic emulsion is used contg. a compd. such as furoylacetyl-*p*-chloro-*o*-phenetidine, which dyes yellow, or various compds. of the general formula

where X represents O or S, R is an aryl or azole group, and R′ is H or a hydrocarbon radical.

Buffered photographic emulsions. Samuel E. Sheppard and Raymond H. Lambert (to Eastman Kodak Co.). U. S. 2,184,023, Dec. 19. A method of making a buffered gelatino-silver halide emulsion having a substantially const. pH within an appreciable portion of the region pH 5.5 to pH 9.5 comprises adjusting the pH of the emulsion to the region pH 5.5 to pH 9.5, and adding to it an org. polybasic or heterocyclic acid, inert with respect to Ag halides, sol. in gelatin contg. at least 12% of water, and having pK values affording a buffering action in the region pH 5.5 to pH 9.5, the org. acid being present in sufficient amt. to buffer the emulsion in the region pH 5.5 to pH 9.5.

Direct positive photographic emulsion. John A. Leermakers (to Eastman Kodak Co.). U. S. 2,184,013, Dec. 19. A method of making a direct positive emulsion comprises incorporating in a gelatino-silver halide emulsion a nonacid optically sensitizing dye for the visible region in an amt. approx. 1½ to 4 times that necessary to give the optimum sensitizing for a normal negative emulsion, and coating the emulsion on a support without fogging it prior to exposure. A thiocarbocyanine dye may be used.

Sheets or films for carrying gelatin emulsions. Henry E. Van Derhoef (to Eastman Kodak Co.). U. S. 2,183,520, Dec. 19. App. is described, and a process of making sheets or films having a surface to which a gelatin emulsion may be made to adhere without the use of substrata which involves depositing an extremely thin discontinuous layer of finely divided water-sol. or water-swellable material such as gelatin on the surface of one of 2 parallel bands disposed in close proximity to one another and moving in the same direction (which may be formed of flexible steel), depositing over the first layer a layer of thermoplastic cellulose deriv. material such as a cellulose acetate compn. in finely divided form and colloidizing the material into a sheet by applying a progressively increasing pressure for a certain length of travel of the bands and at a temp. sufficient for colloidizing the cellulose deriv.

Photographic antihalation layers. Samuel E. Sheppard and Robert C. Houck (to Eastman Kodak Co.). U. S. 2,184,024, Dec. 19. Antihalation layers are formed of unsensitized gelatin contg. an alloxan, an alloxantin or triketohydrindenehydrate. Cf. *C. A.* **33**, 2054[8].

Light-sensitive and printing layers. Charles Dangelmajer (to E. I. du Pont de Nemours & Co.). U. S. 2,184,288, Dec. 26. A printing device is obtained by use of a light-sensitive layer comprising polyvinyl alc., an agent such as a dichromate adapted to promote photochem. hardening of the polyvinyl alc., and 0.1–20% of a monobasic carboxylic acid contg. at least 5 C atoms, such as linoleic acid or a salt of such an acid. U. S. 2,184,289 relates to the like use of polyvinyl alc. with 0.3–20% of an org. sulfonyl compd. such as 1,5-naphthalenedisulfonic acid.

Light-sensitive material suitable for obtaining contrasts. Cornelis J. Dippel, Roelof J. H. Alink and Klaas J. Keuning (to N.-V. Philips' Gloeilampenfabrieken). U. S. 2,183,447, Dec. 12. A light-sensitive material adapted to be physically developed after exposure comprises a support of a transparent lyophile colloid such as regenerated cellulose, a light-sensitive system within a portion of the support and comprising a diazonium compd. and a metal salt such as $HgNO_3$ which is reducible to a metal in an aq. soln., and means such as basic Bi nitrate within this portion for producing local variations in the concn. of the diazonium compd. and for reducing the gradation value of the light-sensitive system.

Photographic images on light-weight metals such as aluminum or its alloys. Alexander Jenny, Nikolai Budiloff, Hans Becker and Kurt Anton. U. S. 2,184,599, Dec. 26. A thin sheet of metal is provided with a chem. coating consisting substantially of a compd. of the metal, such as the oxide, and the coating is impregnated with a photochem. active material such as one contg. active Ag salts and the latter is converted into a photographic image of variable d.; the photographic image is then reproduced by interposing the sheet between a source of x-rays and a receiving surface sensitive to such rays (the photographic image being composed of a material substantially less permeable to x-rays than the light-weight metal).

Automatic developing and finishing apparatus for photographic sheet materials. Samuel Hershberg. U. S. 2,183,742, Dec. 19. Various structural and operative details.

Supplying formaldehyde to photographic developing baths. Lowell E. Muehler (to Eastman Kodak Co.). U. S. 2,184,053, Dec. 19. A solid compn. comprising paraformaldehyde, an alk. salt such as Na_2CO_3 and a neutralizing or buffering agent is for use with developing baths contg. a developing agent and Na_2SO_3. Numerous examples are given.

Light filters. Earl M. Lowry (to Kodak Ltd.). Brit. 508,447, June 30, 1939. A filter that absorbs red and infrared light and is useful in handling photographic material sensitive to such light, e. g., in spooling and packaging the film, comprises a colloidal medium, e. g., gelatin, having dispersed therein an acetate of a metal, e. g., Cu or Ni, and an alkanolamine, e. g., an ethanolamine such as triethanolamine. Cf. *C. A.* **34**, 38[8].

Photographic and printing media. Frederick M. Meigs and Charles Dangelmajer (to E. I. du Pont de Nemours & Co.). U. S. 2,184,310, Dec. 26. A light-sensitive layer is used comprising polyvinyl alc., together with sufficient of a polybasic carboxylic acid such as maleic acid to give the layer a high ink-receptivity, and a light-sensitizing agent. U. S. 2,184,311 (Frederick M. Meigs, sole inventor; to same assignee) relates to compns. of generally like character except that dispersed rubber is used for giving high ink-receptivity.

Coloring photographic images Prussian blue. Lyne S. Trimble (to Cinecolor, Inc.). U. S. 2,183,661, Dec. 19. A process of producing a Prussian blue image from a Ag image involves treating it with a soln. contg. ferric and halide ions, such as an acid soln. of $FeCl_3$ in alc., and treating the resultant image with a soln. of sol. ferrocyanide converting the image thus formed to ferrous ferrocyanide, oxidizing this to ferric ferrocyanide, and removing the Ag salt present, as by use of a strong $Na_2S_2O_3$ soln.

Color-printing plates. Walter S. Marx, Jr. (to Printing Arts Research Laboratories, Inc.). U. S. 2,183,143, Dec. 12. A method of prepg. printing plates for multicolor printing of matter contg. black lines involves photographically printing a black and white positive of the matter on a sheet of transparent material while photographically printing the black lines on the positive more lightly than the black lines in the original matter, and representing the color scheme with the exception of black color, upon the sheet.

Color photographs. Anne H. J. de Lassus Saint Genies. U. S. 2,183,305, Dec. 12. A method of obtaining a photograph in color consists in first obtaining by the lenticular process of photography a primary image in black and white composed of a plurality of monochrome components, and then subjecting without fixing of the sensitive salts

each monochrome component of the primary image successively to treatment including an exposure made selective by the lenticular support and a development assocd. with a diffusive coloring operation producing a color complementary to that which is finally to be obtained in the particular monochrome component treated, the coloration extending over the microscopic elements adjacent the elements of each monochrome component treated and giving a dye substantially proportional to the quantity of silver reduced in each partial development, and finally removing the reduced silver from the photograph.

Color pictures. Eastman A. Weaver (to Comstock & Wescott, Inc.). U. S. 2,183,598, Dec. 19. A method of making an accurate reproduction of an object field with the aid of color aspect records, by using several coloring-matters, at least one coloring-matter being deficient because having an improper absorptivity for light of a color which should properly only be absorbed by a second coloring-matter corresponding to another color aspect, comprises the steps of producing positive and negative prints of different color aspects including those corresponding to the coloring-matters, the contrast values of the positive and negative prints, respectively, being made proportionate to the proper and improper absorptivities of the coloring-matter, and producing a composite record from one of the positive prints of one color aspect and one of the negative prints of another color aspect, thereby subtracting at each point of the reproduction as much of the second coloring-matter as corresponds to the improper absorption at that point by the first coloring-matter.

6—INORGANIC CHEMISTRY

W. C. FERNELIUS AND L. L. QUILL

A new purification process for mercury. Alfred Dobrowsky. *Chem.-Ztg.* **64**, 32(1940).—Hg, enclosed in a thick-walled bottle, is covered with a cold-satd. soln. of $KMnO_4$ and shaken vigorously. After a short time the color changes to green or brown and the Hg is emulsified in the form of a heavy sludge. The purification may be considered complete if after 30 sec. of shaking the permanganate color remains. Otherwise, H_2O is added, the contents are again shaken, and decanted, and the treatment is repeated. After repeated filling and decanting, some dil. HNO_3 is added; this dissolves the MnO_2 and breaks the emulsion. Various known purification processes are compared. A. H. Krappe

The chemistry of europium. W. A. Taebel and B. S. Hopkins. *Trans. Illinois State Acad. Sci.* **32**, No. 2, 132–3(1939).—A review. J. H. Reedy

The separation of cerium from monazite earths. I. A. Atanasiu and M. Babor. *Bull. sect. sci. acad. roumaine* **20**, No. 1–3, 27–31(1938)(in German).—The method of Neckers and Kremers (*C. A.* **22**, 1919) is modified in that the electrolytic oxidation is effected in a soln. obtained by cold-water extn. of the mass obtained by treating monazite with concd. H_2SO_4 and evapg. to fumes. For concns. of $Ce_2(SO_4)_3$ up to 5.8% the soln. must contain 12% free H_2SO_4; for concns. of 5.8–11.5%, 20%; and for concns. of 11.5–29.3%, 25%. The most concd. soln. obtainable had, aside from the H_2SO_4, the compn.: $Ce_2(SO_4)_3$ 29.3, $Th(SO_4)_2$ 20.5, $(La, Di, Yb)_2(SO_4)_3$ 27.7%. Solubilities of Ce^{IV} and Th^{IV} phosphates in 10% H_2SO_4 are 0.15 and 24%, resp. The anode, of large area, was gauze of Pt or of peroxided Pb; the very small cathode, of Pt. The best oxidation conditions and corresponding results were: soln. 29.3% $Ce_2(SO_4)_3$, 25% H_2SO_4, 8 hrs. at 3 v., 1.2 amp., anode c. d. 1 amp. per sq. dm.; 98.9% of the Ce was pptd. as phosphate by diln. to 10% H_2SO_4 content; Th and other rare earths remained in soln. The gelatinous ppt. carried out large amts. of other materials but these were largely removed by thorough decantation and washing with hot water or hot 2% sulfuric acid. D. W. P.

Ceric phosphate. I. A. Atanasiu and M. Babor. *Bull. sect. sci. acad. roumaine* **20**, No. 1–3, 32–4(1938)(in German).—Ceric phosphate pptd. from soln. (preceding abstract) and heated to various temps. was analyzed for Ce, PO_4^{---} and H_2O; at 110° it was $Ce_3(PO_4)_4.11H_2O$ (gelatinous, white to pale greenish), at 200° the pentahydrate (bright-yellow powder) and at 500° the anhyd. compd. (white powder). The percentage solubilities at 100° of the materials freshly pptd., dried at 110° and ignited, resp., were H_2O 0, 0, 0; 5% H_2SO_4 0.083, 0.08, 0; 10% H_2SO_4, 0.14, 0.15, 0; 5% HCl, 0.02, 0.2, 0; 10% HCl, 0.05, 0.3, 0; 5% HNO_3, 0.12, 0.1, 0; 10% HNO_3, 0.18, 0.15, 0; 60% HNO_3, sol., sol., 0.1; 10% AcOH, 0, 0, 0. D. W. Pearce

The chemistry of germanium. Arakel Tchakirian. *Ann. chim.* **12**, 415–99(1939).—Compds. of Ge are compared with compds. of the elements of the same group, principally, C, Si, Pb and Sn. A new method of isolation of Ge is based on the lack of reactivity of GeO_2 with H_2S in presence of $(NH_4)_2C_2O_4$. Reduction of GeO_2 with H_3PO_2 in presence of 3 *N* HCl gives bivalent Ge, which can be sepd. as the dihydrate with NH_3. Reduction of GeO_2 with H_3PO_2 in 2–3% HCl ppts. a black powder, some of which deposits on the side of the flask. This powder may be pure Ge or one of its suboxides, which appear to have similar properties. GeI_4 was prepd. by the direct action of HI on GeO_2. With $H_2C_2O_4$, GeO_2 gives $H_2[Ge(C_2O_4)_3]$ (I), which forms 1.2quinine (II) and 1.2strychnine (III). Solubilities in H_2O at room temp. are II 0.5%, III 0.7%. II and III have coördination nos. of 6 in contrast to Zr oxalate salts of quinine and strychnine, which have coordination nos. of 8. Two mols. NaOH neutralize 5 mols. of GeO_2 but in presence of mannitol, glycerol or sugar 1 mol. of NaOH is equiv. to 1 mol. of GeO_2. Germanic acid forms complex salts with strong electrolytes. Temp. affects the formation of these complexes and since they are not formed instantaneously the mol. may undergo hydration and give a salt different from the original

$$2\left[\begin{matrix} & O_3 \\ Ge & \\ & A_n \end{matrix}\right]\begin{matrix} H_2 \\ \\ C_n \end{matrix} + H_2O \rightarrow \left[\begin{matrix} & O_7 \\ Ge & \\ & A_n \end{matrix}\right]\begin{matrix} H_8 \\ \\ C_n \end{matrix}$$

(where A is an anion, C is a cation and *n* a whole number). Complex salts were formed with LiCl, $LiNO_3$, NaCl, KCl, $MgCl_2$, $Mg(NO_3)_2$, $CaCl_2$, $Ca(NO_3)_2$, $SrCl_2$, $BaCl_2$ and $MgSO_4$ at room temp. and 65°, and the pH of the solns. was measured. Germanoformic acid is similar to formic acid. $CsGeCl_3$ is formed by the addn. of HCl soln. of $GeCl_2$ to CsCl. $C_2H_5I + CsGeCl_3 \rightarrow C_2H_5GeCl_3$, b_{18} 60° (yield 60%); $C_6H_5I + CsGeCl_3 \rightarrow C_6H_5GeCl_3$, b_{19} 115° (yield 80%); $CH_2I_2 + 2CsGeCl_3 \rightarrow CH_2(GeCl_3)_2$, b_{18} 110° (yield 80%); $C_2H_5GeCl_3 + 2H_2O \rightarrow C_2H_5GeOOH + 3HCl$; $CH_2(GeCl_3)_2 + 4H_2O \rightarrow CH_2(GeOOH)_2 + 6HCl$. 183 references. R. F. D.

Reclaiming iodine residues. IV. F. Th. van Voorst. *Chem. Weekblad* **36**, 754(1939); cf. *C. A.* **25**, 2816, 5636.—Waste titration solns. are made acid, and CuI is pptd. by addn. of $CuSO_4$ and $NaHSO_3$. The ppt. is decanted, filtered, and dried in a Büchner funnel. To 50 g. CuI are added 35 g. $K_2Cr_2O_7$, 500 cc. H_2O and 100 cc. 96% H_2SO_4; this mixt. is placed in a distg. flask provided with an air-cooled condenser. Distn. liberates the I, which collects on the walls of the condenser. This procedure produces I free from Cl_2 and Br_2. N. Bekkedahl

The reduction of titanium oxide with solid carbon and with carbon containing iron. W. Baukloh and R. Durrer. *Stahl u. Eisen* **60**, 12–13(1940).—Curves of loss of O *vs.* time in hrs. are shown for the reduction of TiO_2 with graphite at various temps. with no Fe present and in the presence of Fe. With Fe present the rate of reduction at 1200° is increased about 10-fold. S. Epstein

The chemistry and morphology of the basic salts of bivalent metals. IX. Basic nickel nitrates. W. Feitknecht and A. Collet. *Helv. Chim. Acta* **23**, 180–97

(1940).—Expts. dealing with the reaction of $Ni(NO_3)_2$ with NaOH are described. As in the case of $NiCl_2$ (cf. *C. A.* **34**, 1267[9]), a basic salt is obtained that gradually changes into the hydroxide. Expts. on the aging reaction at various concns. and at temps. ranging from room temp. to 100° lead to 5 basic salts of different structures. The following "ideal formulas" are proposed: (I) $Ni(NO_3)_2.Ni(OH)_2.6H_2O$, (II) $Ni(NO_3)_2.3Ni(OH)_2$, (III) $Ni(NO_3)_2.3.8$–$7.4Ni(OH)_2.1.3$–$9.0H_2O$, (IV) $Ni(NO_3)_2.4Ni(OH)_2.7H_2O$, (V) $Ni(NO_3)_2.7.8Ni(OH)_2.xH_2O$. I has a lattice of complex ions and its constitution is given by $[Ni(H_2O)_6][Ni(NO_3)_2(OH)_2]$. The respective crystallographic structures are discussed. Robert Simha

Derivatives of calcium cyanamide. VI. The formation of guanidine from dicyanodiamide. 2. Reactions between dicyanodiamide and ammonium salts. Kiitiro Sugino. *J. Chem. Soc. Japan* **60**, 267–75(1939); cf. *ibid.* **60**, 111–21(1939).—The reaction between dicyanodiamide and NH_4 salts was studied both in molten state and in aq. soln. with the purpose of finding the best conditions for the prepn. of guanidine. Heat production is greatest on reaction with NH_4NO_3; NH_4Cl, NH_4Br and NH_4I produce approx. equal quantities of heat; with $(NH_4)_2SO_4$ and NH_4ClO_4 melting occurs, resp., at 175° and 167° with simultaneous heat production due to guanidine formation; $(NH_4)_2HPO_4$ decomposes to $NH_4H_2PO_4$ and NH_3 at high temp. and heat production is not observable. Yields of guanidine are with NH_4NO_3 73%, NH_4Cl 88%, NH_4Br 87%, NH_4I 83%, $(NH_4)_2SO_4$ 62%, NH_4ClO_4 67%, and $(NH_4)_2HPO_4$ 46%. The optimum conditions for the prepn. of guanidine are: Heat a mixt. of dicyanodiamide and NH_4NO_3 at 180–200° for less than 5 min. A special cooling system should be used. Mixts. with NH_4Cl, NH_4Br and NH_4I require heating for 30 min. at 180–200° with special cooling system. Heating 0.037 mol. of dicyanodiamide with 0.0407 mol. of NH_4NO_3 or NH_4Cl and either 3 or 10 cc. water in a sealed tube at 150–80° for 1–2 hrs. gives guanidine. Similarly $(NH_4)_2SO_4$ and dicyanodiamide with 3 cc. water at 160–80° gave a yield of 77%. With a greater amt. of H_2O the yield decreased, owing to hydrolysis of the product and other side-reactions. A low yield from $(NH_4)_2HPO_4$ in the presence of water is attributed to the alky. of the soln. resulting from the hydrolysis of the phosphate. K. Shinohara

Aluminum fluoride and double salts derived therefrom. V. Caglioti. *Chimica e industria* (Italy) **20**, 274(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 628.—The structure and chem. behavior of AlF_3 were investigated, including the formation of artificial cryolite, and especially of pseudocryolite, $NaAlF_4.nH_2O$, the structure of which is identical with that of cryolite, save for a slight widening perpendicular to the *c*-axis. C. A. Silberrad

The absorption of carbon monoxide by copper ammonium solution. K. Ya. Markevich. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 10, 31–5(1939).—CO is absorbed by cuprous ammonium formate solns. and forms a complex which breaks down to give CO_2 and Cu_2O or Cu. When absorption begins, some time elapses before the complex begins to break down. The induction period varies with temp. Absorption of CO is independent of CO pressure, and depends on concn. of the ammoniacal cuprous ion. Each mol. of Cu_2O absorbs 0.85 mols. of CO. Below 20°, CO is oxidized chiefly by Cu_2O and above 20°, by CuO. Formation of Cu decreases the absorbing power of the soln. This can be prevented by addn. of 20% by vol. of O_2 to the CO to maintain the CuO concn. When O_2 is not added, oxidation is directly proportional to temp. and Cu_2O concn. In the presence of O_2, oxidation is inversely proportional to temp. and O_2 concn. H. M. L.

Reaction of ethers with chromous halides [complex produced] (Hein, Kraft) **10**.

7—ANALYTICAL CHEMISTRY

W. T. HALL

New evaluation of analytical methods. A. Schleicher. *Z. anal. Chem.* **118**, 82–9(1939).—A discussion of the changes accomplished by the use of microchemical methods and various types of phys. instruments such as the spectroscope. Methods of evaluation are discussed and a mathematical expression is prepd. for expressing the usefulness of a procedure. W. T. H.

Complete gravimetric analysis by direct precipitation in a Jena filtering crucible. G. G. Longinescu and I. I. Prundeanu. *Bull. sect. sci. acad. roumâne* **19**, 132–40 (1937–38); *Bul. Chim., Soc. Române Chim.* **39**, 19–25 (1937–38).—The necessary technique is illustrated by the detn. of Pb as $PbSO_4$, Pb as PbS, sepn. of $PbSO_4$ from $BaSO_4$, detn. of HCl or HBr as Ag salts and sepn. of Ca, Ba and Sr by means of EtOH. The advantages claimed for this technique (*C. A.* **30**, 7479[8]) appear to have been substantiated. W. T. H.

Octyl alcohol in volumetric analysis. L. J. Sheps and L. A. Breault. *Can. Chem. Process Inds.* **23**, 530(1939).—Exptl. data show that a 1% soln. of phenolphthalein in a 50-50 mixt. of EtOH and octanol (2-ethylhexanol) is suitable for: (1) detg. the free alky. of aq. solns. of fatty alc. sulfates; (2) titration to the phenolphthalein end point in aq. soln. of alk. soap-like products and (3) titration of AcOH in water. W. H. Boynton

Some essential corrections in gas analyses. J. J. Leendertse and F. E. C. Scheffer. *Rec. trav. chim.* **59**, 3–13(1940); cf. *C. A.* **26**, 1873.—It is emphasized that analyses of gases made at const. vol. require corrections for nonideality. Two corrections are calcd.: the Dalton correction, which takes into account the fact that the resultant pressure after mixing two gases is not the sum of their original pressures, and the Avogadro correction, which is applied to the pressure-vol. product, since equal vols. of gases do not contain equal nos. of mols. Numerical corrections are calcd. for various simple hydrocarbons and their mixts. The corrections are particularly important in mixts. involving propane and butane, less important in mixts. involving methane and ethane. J. E. V.

Copper sulfate as a standard for thiosulfate titrations. N. Schoorl. *Pharm. Weekblad* **76**, 1441–6(1939).—A review with discussion of the literature. J. C. J.

Potentiometric analysis of the metals of the ammonium sulfide group. H. Steuer. *Z. anal. Chem.* **118**, 386–98 (1940).—*To det. Cr*, the acid soln. can be oxidized by $(NH_4)_2S_2O_8$ in the presence of Ag^+ and, after the excess persulfate is destroyed by boiling, the soln. can be titrated with $SnCl_2$ in an atm. of CO_2 provided Mn, Hg, Fe and V in the higher valence states are absent. Sexivalent U does no harm. The titration also succeeds with $FeSO_4$ if septavalent Mn and quinquevalent V are absent. In the presence of a little Tl salt as catalyzer, trivalent Cr can be titrated with $K_4Fe(CN)_6$ soln. if the soln. is strongly basic, and contains KCl in an atm. of CO_2. *To det. Al*, the only useful potentiometric method depends upon the formation of $[AlF_6]^{---}$. To carry out the analysis, first neutralize the soln. to phenolphthalein, sat. with NaCl and add an equal vol. of EtOH. Add a drop of 20% $FeCl_3$ soln. and titrate with 0.1 *N* NaF soln. in a closed vessel contg. CO_2. The reaction is slow and it is

necessary to wait a definite time after each addn. of the reagent and to shake uniformly. *The detn. of Ti* is best accomplished by reducing with Zn under a Contat-Göckel valve and finally titrating with $K_2Cr_2O_7$ in an atm. of CO_2. *For the detn. of U*, a strong reducing agent must be used to obtain all the U in the bivalent state. $SnCl_2$ is not adequate but in a soln. strongly acid with HCl, $TiCl_3$ will accomplish complete reduction at 60° in the presence of tartrate. The reduction can be followed with the potentiometer. Another method consists in reducing the UO_2^{++} with Zn and HCl to the quadrivalent state and titrating with $K_2Cr_2O_7$ at 80° but too much time is required. The *detn. of Fe* can be followed potentiometrically when the reduction with $SnCl_2$ or with $TiCl_3$ is measured or when the Fe^{+++} is first reduced in a Jones' reductor and the resulting Fe^{++} is titrated with dichromate. By a combination of these methods it is possible to det. all the above-mentioned ions in the presence of one another. The potentiometric *detn. of Mn* can be based upon (*a*) oxidation of the Mn^{++} to the valence of 7 and titration of the MnO_4^- with oxalic acid at 70–80°, (*b*) titration with $K_3Fe(CN)_6$ soln. in an ammoniacal soln. contg. citric acid or (*c*) direct oxidation of the Mn^{++} to Mn^{+++} by $KMnO_4$ in the presence of fluoride. The *detn. of Co* can be based on the titration with KCN soln. whereby Co unites with 5 CN but the presence of NH_3, Ag, Hg, Cu, Zn or Cd salts interferes; the Co can also be detd. by oxidation in an alk. citrate soln. by means of $K_3Fe(CN)_6$ soln. The *detn. of Ni* can be accomplished with KCN and, unlike the case of Co, the presence of NH_3, Ag, Hg, Cu and Cd does no harm. An excellent potentiometric method for *titrating Zn* is based on the reaction with Na_2S. With a suitable combination of these methods a systematic procedure for detg. Mn, Co, Ni and Zn by potentiometric titrations is described. Excellent results were obtained for all the titrations described in this paper. W. T. H.

Determination of aluminum with 8-hydroxyquinoline in the presence of iron and phosphoric acid. Gr. Bălănescu and Maria D. Motzoc. *Z. anal. Chem.* **118**, 18–26(1940).—The various methods of detg. Al in the presence of Fe are reviewed and the conclusion is drawn that the sepn. by means of an excess of NaOH is the simplest procedure. The results, however, are almost invariably low as a result of absorption of Al by the hydrated iron ppt. In expts. with the equiv. of 0.1–0.35 g. of Al_2O_3 and 0.04–0.125 g. Fe_2O_3, the sepn. of Fe and Al by means of NaOH was much better when sufficient Na_2HPO_4 was first added so that the ratio wt. Fe/wt. P_2O_5 = 2. The procedure recommended is the following: From an aliquot part of a soln. contg. Fe^{+++}, Al^{+++} and H_3PO_4, det. the Fe volumetrically. In a 2nd aliquot det. the H_3PO_4 by a suitable molybdate method. Then to a 3rd aliquot add Na_2HPO_4 soln. until the desired ratio is obtained, make the soln. basic with NaOH and, when all Fe^{+++} is pptd., add 5 ml. of 2 *N* NaOH in excess. Heat slowly to boiling, filter, wash with dil. NaOH and use the filtrate for the Al detn. Make the soln. slightly acid to phenolphthalein, heat till the last of the turbidity due to $Al(OH)_3$ disappears, add 3% oxine soln. and filter off the Al hydroxyquinoline deriv. Dissolve this in 3 *N* HCl and base the Al detn. on the Br required to react with the soln. on treatment with KBr + $KBrO_3$. One mole of Al_2O_3 is equiv. to 8 atoms of Br. In 10 analyses without the addn. of Na_2HPO_4 the av. error was −3.6% of the actual quantity of Al present, but after the addn. of phosphate the av. error was only −0.02%. With no Na_2HPO_4 the greatest error was −6.66% but after the addn. of phosphate the greatest error was +0.95% of the actual Al_2O_3 content. W. T. H.

A simple method for the determination of aluminum in ferrotungsten and tungsten steels. S. Sinkai and T. Nagata. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 397(1939).—Dissolve 2 g. of sample in HNO_3-HF in a Pt dish, add H_2SO_4 and evap. the mixt. to dense white fumes. Dil. to exactly 500 cc., filter and take 250 cc. of the filtrate. Neutralize with NaOH soln., and add sufficient excess 0.5 *N* NaOH soln. to dissolve the $Al(OH)_3$. Heat the mixt. on a water bath. Cool, again dil. to exactly 500 cc., filter and evap. 250 cc. of the filtrate to approx. 100 cc., add NH_4Cl and boil the mixt. Make slightly alk. with NH_4OH and again boil. Filter, wash the ppt. with hot water contg. a little NH_3 and some NH_4NO_3, ignite to Al_2O_3 and weigh. George Ayers

Spectral-analytical determination of low aluminum contents in steel and iron. Gerhard Hartleif. *Arch. Eisenhüttenw.* **13**, 295–7(1940).—Small samples taken in small chill molds are most suitable as they solidify very quickly. Forge into rods of about 15 × 30 sq. mm. Rapid solidification prevents segregation of the Al_2O_3 and uniform samples for producing spark spectra are obtained. The lines selected for the analysis are the line Al$_\alpha$ 3961.5 in combination with line Fe$_\alpha$ 3903.1. The electrode is a Cu rod 4 mm. in diam. with weak curvature at the end. The spark is produced by an inductor of 3000 cm. capacity and 800,000 cm. self-induction. The error in this method is of about the same order as in the chem detn. for uniform, quickly solidified samples. With slowly cooled steel a greater error results if Al_2O_3 veins have formed in the steel. M. Hartenheim

Gravimetric determination of antimony with 8-hydroxyquinoline. Th. I. Pirtea. *Z. anal. Chem.* **118**, 26–30 (1939).—By means of oxine, 12 γ of Sb can be detected in 5 ml. of a soln. of $SbCl_3$ or of tartar emetic. The pptn. is quantitative at pH 6–7.5. For the pptn., prep. the reagent by dissolving 7–8 g. of oxine in as little glacial AcOH as possible, dil. with 200 ml. of water, add 6 *N* NH_4OH until a slight turbidity remains and clear this with a drop of AcOH. To the Sb soln. contg. 0.5–1.5 g. Sb and an excess of HCl, add 30 ml. of the oxine reagent, heat to 60–70° and neutralize slowly with 10% NH_3 soln. At pH 1.5 a yellow ppt. begins to form and pptn. is complete near the neutral point when the soln. is strongly yellow. Heat a little longer and give the contents of the beaker a rotary motion so that the ppt. will collect on the bottom. If the soln. still smells of AcOH, add enough NH_3 to remove the acid and leave a faint odor of NH_3. Allow to cool for 2 hrs., filter through a filtering crucible, wash the ppt. with a cold soln. contg. 0.2–0.4 g. oxine and a few drops of AcOH per l. until the filtrate will give no test for halogen with $AgNO_3$ + HNO_3. Dry to const. wt. at 105–110°. The ppt. is yellow and contains 21.97% Sb. The test analyses were within 1 mg. Sb of the true value. W. T. H.

Detection of cadmium and magnesium. Edwin Ecgriwe. *Z. anal. Chem.* **118**, 98–100(1939). To test for Cd, take 1 drop of the neutral soln., add 0.5 ml. of 15% $Na_2CO_3.2H_2O$ soln., 0.25 ml. of a soln. of 0.5 g. diazoaminobenzene in 100 ml. of acetone and a few drops of $CHCl_3$. If Cd is present an orange-yellow color will be imparted to the $CHCl_3$ on shaking. As little as 0.2 γ of Cd suffices to give the test. Cu gives a greenish coloration and Ag a brownish yellow one. Both metals interfere as do Co and Ni. The test can be obtained with 3 γ Cd and 100 times as much Pb, Mn, Zn and Mg. A test for Mg, of approx. the same sensitivity, can be obtained with a little *p*-aminophenol hydrochloride. The test can be applied to 1 drop of a neutral soln. contg. no NH_4 salts in the residue obtained from the soln. of the Group V ppt. To one drop of soln. add a few drops of concd. NH_3 soln. and a little of the solid reagent. Shake a few times and wait a little. An oxidation of the org. reagent begins to take place soon, the soln. gradually becomes a pale yellow, then a light yellowish brown. If the ppt. of $Mg(OH)_2$ is present it adsorbs the dyestuff and the brownish color soon becomes blue. Cations which yield ppts. with NH_4OH interfere. W. T. H.

Estimation of submicroquantities of calcium. Albert E. Sobel and I. Allan Kaye. *Ind. Eng. Chem., Anal. Ed.* **12**, 118–20(1940); cf. *C. A.* **33**, 7835³.—Ca can be detd. iodometrically in amts. of 0.004–0.04 mg. with an av. deviation of ±1.2% with the aid of an ordinary 5- to 10-ml. microburet and a special centrifuge tube. The method is directly applicable to the *detn. of Ca in* as little as 0.2 ml. of fresh *blood serum*. The Ca is pptd. as oxalate, the washed ppt. is dissolved in a measured vol. of 0.01 *N* HCl and the excess H^+ is detd. iodometrically.

T. H. Dunkelberger

Determination of cerium with 8-hydroxyquinoline. Th. I. Pirtea. *Bul. Chim., Soc. Române Chim.* **39**, 83–5 (1937–8)(in German).—To 20–40 ml. of a neutral soln. contg. up to 0.10 g. of Ce^{+++}, add 5 ml. of 2 *N* AcOH and a slight excess of a 3% soln. of oxine in EtOH. No ppt. will form. Now add from a pipet 10% NH_3 soln. until the Ce is pptd. The ppt. has a yellow-orange color which slowly becomes brownish purple. The latter compd. has the more definite constitution. After the change in color is complete, heat to boiling, filter through a glass filtering crucible, wash with hot water, dry and weigh. The ppt. has the formula $Ce(C_9H_6ON)_4.2H_2O$. Obviously an oxidation of the Ce^{+++} has taken place. The ppt. contains only 18.73% Ce. The results obtained in 14 expts. in which the ppt. was weighed were excellent, but it takes so long to complete the transformation to ceric salt that it is more practicable to ignite the ppt. and weigh the residual CeO_2. Good results were obtained in 10 analyses. W. T. H. [1] [2] [3]

Separation of copper from nickel with sodium thiosulfate in the analysis of German silver. Imre Sarudi (nee Stetina). *Z. anal. Chem.* **118**, 13–17(1939).—To analyze German silver dissolve 0.4 g. of alloy in 8 ml. of 7.5 *N* HNO_3. Add 1 ml. of concd. H_2SO_4 to the resulting soln. and evap. to fumes. Dil. with water to make 100 ml. of soln., make neutral with 10% NH_4OH, add 50 ml. of 10% $Na_2S_2O_3$ and 20 ml. of 6 *N* H_2SO_4 and boil 15 min. to ppt. all Cu as CuS. Filter and reserve the filtrate for the detn. of Fe, Ni and Zn. Ignite the ppt. of CuS to CuO, fuse with $K_2S_2O_7$, dissolve the melt in water, add a little AcOH and det. the Cu iodometrically. Take the filtrate from the CuS pptn. and evap. to dryness to remove the greater part of the H_2SO_4. This leaves most of the S in the filtrable condition but on addn. of water a little colloidal S is obtained. Remove this by heating with Br water. Filter and det. the Ni with dimethylglyoxime. In the filtrate destroy the excess reagent by boiling with Br water and det. the Zn as $ZnNH_4PO_4$. Use sep. samples of the alloy for the detn. of Sn as SnO_2 and Pb as $PbSO_4$. Test results show that the method is satisfactory. W. T. H. [4] [5]

New method for the detection of gold in qualitative analysis. Lawrence S. Malowan. *Z. anal. Chem.* **118**, 100–102(1939).—Zn, Cd and Cu solns. can be neutralized by morpholine and insol. ppts. are formed. But beside this neutralizing and pptg. effect of the amine, it is characterized by being readily oxidizable. I_2 is reduced by it to HI and noble metals are pptd. from solns. This applies in particular to the detection of Au. Take 2–3 ml. of soln. to be tested, add 0.3 ml. of pure morpholine, or enough to impart a distinctly basic reaction to the soln. and filter to remove any Cu or Fe ppts. Heat the filtrate to boiling. If Au ions are present the soln. will be yellow and will gradually assume a bluish violet tint and bluish violet flocks will ppt. From the appearance of the test an approx. estn. of the Au content can be made. W. T. H. [6] [7]

Determination of lead, thorium and uranium in zircon with respect to the geological estimation of time. F. Hecht and F. Korkisch. *Mikrochemie* **28**, 30–63(1939).—It is important, if the contents of Pb, Th and U are to be used as a basis for measurement of geologic time, that the detns. should be as accurate as possible. The procedure described in this paper represents a combination of macro- and micro-methods. Only 1 g. of material is required and the 3 elements are detd. in a single weighed sample. Good results were obtained in the analysis of synthetic mixts. The sample of mineral is weighed into a crucible of chemically pure Ag whose Pb content has been detd. accurately. It is mixed with 10 g. of pure Na_2O_2 and covered with a layer of Na_2CO_3. The Ag crucible is then placed within a larger porcelain one and slowly heated until the contents melt. After 30 min. at the m. p., the fused product is treated with water and after removal of the crucible, dissolved in dil. HNO_3. The soln. is evapd. to dryness 3 times with concd. HNO_3. The residue is taken up in HNO_3 and hot water and the SiO_2 filtered off. The SiO_2 ppt. is examd. by removing the Si with HF, fusing with $K_2S_2O_7$, digesting with HNO_3, examg. the residue for $PbSO_4$ and the soln. for Th and U. The $UO_2(NO_3)_2$ is sepd. from Pb and Th by evapg. the HNO_3 soln. to dryness and then after the addn. of a little HNO_3 extd. by means of ether in a Soxhlet app. Eventually, after a lengthy treatment, the UO_2 is detd. by pptn. with 8-hydroxyquinoline and finally weighed as U_3O_8. The Pb is detd. after pptn. with H_2S and conversion of the PbS into $PbSO_4$, in which form it is finally weighed. The Th is eventually pptd. by treatment with fluoride and finally weighed as ThO_2. In order to obtain accurate results, great attention was paid to the purity of all the ppts. Some of the recorded weighings are to 7 significant figures and the final results in all cases appear to be satisfactory, although very great precautions had to be taken to get results accurate within a few % of the truth when the content was low. W. T. H. [8]

Improvement in the determination of lithium in mineral waters and a new method for determining lithium in silicates. Oskar Hackl. *Z. anal. Chem.* **118**, 1–9(1939).—One of the best methods for detg. Li in mineral waters is Winkler's procedure of dissolving out LiCl from a mixt. of alkali metal chlorides by means of iso-BuOH and eventually weighing the Li as $LiSO_4$. An arbitrary correction of 0.5 mg. is usually subtracted for each 10 ml. of the alc. used to allow for other chloride dissolved, but this procedure is not altogether satisfactory when accurate results are required. The treatment with iso-BuOH, however, does provide for the sepn. of all the LiCl from most of the NaCl and KCl, but instead of converting this directly to sulfate it is better to remove any Mg present by neutralization with NaOH, then evap. to dryness with HCl, heat until all acid is removed, dissolve the residue in 3 ml. of strong NH_3 soln. and ppt. the Li as $LiPO_4$ in the presence of EtOH. In the analysis of minerals, it is recommended to get the alkali metal chloride mixt. in the usual way, ppt. the K as K_2PtCl_6, remove the Pt from the soln. with H and then treat with NaOH or with oxine to remove Mg and finally det. the Na as phosphate. No analytical results are given but the various possibilities are discussed. W. T. H. [9]

Modification of Rauscher's method for determining mercury. Anthony Shukis, Jr., and Ralph C. Tallman. *Ind. Eng. Chem., Anal. Ed.* **12**, 123(1940); cf. Rauscher, *C. A.* **32**, 6174[1].—To eliminate retention of particles of Hg on the surface of the mono- or diethanolamine after reduction, the digestion is carried out in a centrifuge tube. The mixt. is centrifuged for 5 min. at 2800 r. p. m. after digesting. Subsequent soln. and titration of the Hg are carried out in the same tube. The changes do not apply to the gravimetric procedure. T. H. D. [10]

Detection of silver in very dilute solutions by physical development. Aurel I. Velculescu. *Bul. Chim., Soc. Române Chim.* **39**, 141–3(1937–38)(in German).—In a previous paper (*C. A.* **27**, 42) it was shown that a test for Ag in dil. soln. could be obtained by moistening filter paper with a drop of the soln., adding KBr soln. and finally adding a metol developing soln. Later developments of the method showed that both the fixation of the Ag in the paper fibers and also the Ag deposition itself could be facilitated by the presence of a trace of Ag already pptd. A further improvement consists in placing the paper, after it has been moistened with the soln. to be tested, and dried, in an atm. of H_2S for 30 sec. and then washing 6 times by half-min. movement in the water each time. The small quantity of Ag_2S cannot usually be recognized by the eye but the H_2S excess is easier to remove than bromide and the paper now responds well to treatment with metol developer. Instead of the metol soln. previously recommended, a developer contg. 2 g. pyrogallol and 2 g. of citric acid in 500 ml. of soln. gives good results. Just before the developer is used, 60 ml. of it should be treated with 2 ml. of 0.1 *N* $AgNO_3$ soln. The manipulation of the paper is practically the same as in developing films or prints in photographic work. W. T. H. [11]

Determination of titanium in aluminum and light alloys by the method of absolute colorimetry. Marcella Mon-

ticelli and Fabio Sinigaglia. *Alluminio* **8**, 259–64(1939). —The applicability of the Leifo photometer made by Leitz, to the colorimetric detn. of Ti in Al alloys is detd. In the range of Ti up to 0.3% (the amts. likely to be present in Al alloys) Baer's law is applicable. Fe interferes unless H_3PO_4 is added. Up to 2% Ni does not interfere. If Cr is present, it must first be removed.
A. W. Contieri

Determination of fluorine in cryolite by the method of A. Greeff. H. Spielhaczek. *Z. anal. Chem.* **118**, 161–4 (1938).—G.'s method (*C. A.* **7**, 354) depends upon the titration of F^- with $FeCl_3$ soln. in the presence of KCNS, which indicates the presence of excess Fe^{+++}. Each Fe^{+++} used in the titration is converted into $[FeF_6]^{---}$. With insol. F compds. the sample is fused with K_2CO_3 + SiO_2 as recommended in 1824 by Berzelius. Regarding the effect of the SiO_2, G. stated that the theory was not clear but a study of G.'s analytical data shows quite clearly that a water-insol. silicate, such as $Na_3Al(SiO_3)_3$, is formed. After this has been removed from the aq. soln. of the melt, it is customary to make the soln. neutral to phenolphthalein which causes pptn. of hydrated SiO_2 that is usually left in contact with the soln. during the subsequent titration of the F^-. This ppt. adsorbs some of the soln. and thereby causes error. If in the preliminary fusion, the quantity of SiO_2 is kept low (e. g., 1 g. SiO_2:1 g. cryolite) the error is not large and the procedure can be used in tech. analysis but the results of the titration are more consistent and nearer the truth if the SiO_2 is removed by filtration. W. T. H.

The work of the oxygen panel. Review of methods available for estimating oxygen and hydrogen. T. Swinden. *Iron & Coal Trades Rev.* **140**, 5–6, 41–2(1940).—Review of work done by a committee of the British Iron and Steel Institute on detg. O and H in steel.
I. Hartmann

Determination of oxygen in zinc oxide. Max Schutze. *Z. anal. Chem.* **118**, 241–5(1939).—In connection with the evaluation of Zn dust it is often desirable to know the O content. The basis of the method now proposed consists in reducing with C in a stream of N_2, passing the CO formed over I_2O_5 and then detg. either the liberated I_2 or the CO_2. When all the described precautions were taken, the procedure gave for the analysis of very pure ZnO results which were all within about 0.1% of the truth and the average of 5 expts. was 19.63% O (theory = 19.66%).
W. T. H.

Direct oxygen determination in metal oxides and organic substances. Max Schütze. *Naturwissenschaften* **27**, 822(1939).—An accurate method for detg. O in oxides and org. substances is described and typical results are given. The O is converted into CO by heating the C and the CO is oxidized to CO_2, which is detd. Cf. preceding abstr. B. J. C. van der Hoeven

Gravimetric determination of carbon in carboniferous lead concentrates. Wilhelm Enning. *Z. anal. Chem* **118**, 93–4(1939).—Digest 1 g. of sample with 350 ml. of hot *N* HCl. This will dissolve most of the Pb as $PbCl_2$ and leave the C behind. Filter, boil the residue with 220 ml. of 1.2 *N* HCl, filter, wash with hot 0.2 *N* HCl, dry at 110° and weigh the silicious residue + C. Ignite to burn off C and weigh again. W. T. H.

The detection of sulfur adsorbed by activated carbon. J. J. van Eck. *Pharm. Weekblad* **76**, 1569–71(1939).—The following rapid method for the detection of S adsorbed by activated C is useful especially for detecting the presence of mustard gas. Heat in a small combustion tube a few lumps of the C with 5–10 times its wt. of Castellana mixt. after the reaction is over, plunge the hot bottom in 5 cc. of water when it usually cracks. Filter into a short test tube, acidify with dil. H_2SO_4 and sweep out with a current of air any H_2S formed and identify with $Pb(OAc)_2$ paper. A blank must be run on all chemicals used as well as glassware. As activated C often contains S, and prolonged heating in a current of H proved ineffective, the following method is recommended; boil twice with a 10% NaOH soln., evap. to dryness on the waterbath, transfer to a Ni crucible and heat for 30 min. with a blast; boil twice with dil. HCl until Pb acetate paper shows no more H_2S. J. C. Jurrjens

Determination of aluminum oxide in metallic aluminum with cupric ammonium chloride. T. Nakamura and S. Yamazaki. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 296–7(1939).—Add a soln. of 240 g. of $CuCl_2.2NH_4Cl.2H_2O$, in small portions, to 10 g. of the sample; after the reaction is ended, heat and filter the mixt. Wash the ppt. with 1% HCl, dry, fuse the ppt. with $KHSO_4$, then boil the mass with water. Add 10 cc. of 1:1 H_2SO_4, evap. to dryness and, after adding H_2O, filter off the SiO_2. Remove Cu from the soln. with H_2S, then add Br water to the filtrate and remove Fe with NaOH. Finally det. Al in the soln. with 8-hydroxyquinoline and calc. to Al_2O_3. $CuNH_4$ chloride soln. dissolves considerable amts. of $Al(OH)_3$, but very little Al_2O_3; it even dissolves Al-Si alloys. George Ayers

Precipitation of aluminum hydrous oxide and its solubility in ammonia. E. B. R. Prideaux. *Analyst* **65**, 83–7(1940).—Ten ml. of soln. contg. 9 mg. of Al as potash alum was mixed with 5 ml. of 4 *N* NH_4Cl and treated with varying amts. of NH_3 soln. The soln. was heated quickly to boiling and filtered promptly. The Al in the filtrate was detd. with aluminon. The quantity of Al remaining in the filtrate increased up to 1.5 *N* NH_3 but this quantity was not strictly proportional to the excess NH_3 present. Above this concn. the quantity dissolved falls but shows irregularity. The ratio of Al/NH_3 is about the same in 0.75 *N* NH_3 soln. as in the strongest NH_3 soln. The variability in the results is not due to exptl. error, nor to the loss of NH_3 from hot solns. but rather to the fact that alumina pptd. in this way is the most colloidal of all the forms whose properties vary with the speed of coagulation. Pieces of very pure Al were amalgamated with excess Hg and placed in NH_3 solns. of varying strengths. After a day the NH_3 soln. was filtered and it was found that the Al in soln. per ml. was 1.08, 0.36, 0.12 and 0.12 mg. in solns. which were, resp., 5.0, 0.75, 0.50 and 0.25 *N* in NH_3. On standing, alumina was gradually pptd. from the solns. When Al dissolves from an amalgam with evolution of H_2 from solns. which are well on the basic side of the isoelec. point, it is probable that NH_4AlO_2 is formed first. This can then decompose in 2 ways. (1) NH_3 may be lost by evapn. and a coherent skin will form on the surface of the liquid, (2) the NH_4AlO_2 can hydrolyze and thus colloidal alumina is formed which gradually gives a turbidity throughout the entire soln. Based on the expts. described it is recommended in pptg. alumina to add *N* to 2 *N* NH_3 to the soln. contg. the usual quantity of NH_4 salt and then digest the soln. in a closed vessel on the water bath and finally drive off excess NH_3 and filter. W. T. H.

Chemical analysis of aluminum hydrosilicates. Ugo Passarini. *Boll. sci. facolta chim. ind., Bologna* **1940**, Nos. 1–2, 55–7.—A systematic method is given for the detn. in crude and purified Al hydrosilicates of humidity, loss on ignition, H_2O of constitution, SiO_2, Al_2O_3, Fe_2O_3, TiO_2, CaO, MgO, alkali metal oxides, chlorides, sulfides, sulfates, carbonates and org. substances in order to obtain comparable data for working out a catalog of the national (Italian) feldspars and kaolins. Dora Stern

Determination of free magnesia in magnesitic limes. R. Meurice and P. Martens. *Ann. chim. anal. chim. appl.* **22**, 33–40(1940).—When the quantities of silicate and sulfate are small, a rapid method for estg. the MgO content of a sample of lime consists in detg. how much acid is required to dissolve it, how much CaO is dissolved by an ammoniacal soln. of NH_4NO_3 and how much CO_2 is evolved on treatment with acid. Some 18 samples of lime were examd. A longer procedure consists in making a complete analysis of the lime but in many cases the results are not any better. W. T. H.

Routine examination of magnesium trisilicate. J. L. Pinder. *Analyst* **65**, 90–6(1940).—As a result of considerable experimentation undertaken (1) to devise suitable tests for this pharmaceutical including chem. analysis and an adsorption test and (2) to det. whether or not the adsorptive capacity depends in any way on the phys.

condition of the trisilicate, the following conclusions were drawn: (1) The analytical examn. of Mg trisilicate to be used in *medicine* should include detns. of SiO_2, Mg, free and combined H_2O and acid adsorption. Suitable procedures are given for making such an analysis and the analytical results of 5 samples are tabulated. (2) From a study of the time and temp. for a methylene blue adsorption test, it is thought that a 2-day test at room temp. is of value. (3) The wet and dry bulks should be detd. for apparently the ratio of the dry to the wet bulk has some relation to the results of the adsorption test. W. T. H.

Analysis of cadmium-plating solutions. G. Stanley Smith. *Analyst* **65**, 87–90(1940).—Directions for detg. free cyanide, total cyanide, Cd, Cu and Fe are given and some analytical results are shown. W. T. H.

Indirect determination of hydrochloric and hydrobromic acids by transformation of the silver chloride into silver bromide. G. G. Longinescu and Ecaterina I. Prundeanu. *Bul. Chim., Soc. Române Chim.* **39**, 15–16(1937–38)(in French).—In the method now proposed, AgCl and AgBr are pptd. directly in a weighed Jena filtering crucible. Then pressure is produced below the filter so that no more liquid will pass through the filter, a little NH_3 soln. is added and then, after stirring with a rod, some KBr soln. is introduced into the crucible and a little HNO_3 added. The transformation of the AgCl into AgBr is complete by this treatment. The entire treatment takes place in the crucible. If the AgCl and AgBr mixt. is weighed and then the wt. detd. after conversion of all Ag to bromide, the content of both HCl and HBr can be calcd. W. T. H.

Volumetric determination of sulfuric acid in permanganate solutions containing sulfuric acid. Hans Becker. *Z. anal. Chem.* **118**, 263–4(1939).—In the *paper* and *cellulose industry* a soln. of 0.02 *N* $KMnO_4$ is prescribed which is supposed to contain 0.16% H_2SO_4. The free H_2SO_4 can be detd. as follows: Take 20.00 ml. of 0.02 *N* oxalic acid and add 19.00 ml. of the 0.02 *N* $KMnO_4$ + 50 ml. of water. Heat to boiling and when the pink MnO_4^- color has disappeared, add 1.00 ml. more of the $KMnO_4$. If necessary discharge any MnO_4 color with a drop or two more of the oxalic acid. Now add methyl red indicator soln. and titrate with 0.1 *N* NaOH. In calcg. the H_2SO_4, allowance must be made for the fact that during the reduction of the 20 ml. of 0.02 *N* $KMnO_4$, 0.24 milliequiv. of H_2SO_4 is neutralized in addn. to the H^+ ions of the oxalic acid soln. W. T. H.

Determination of the chloride ion by the Volhard method and gravimetrically. Josef Bitskei. *Z. anal. Chem.* **118**, 164–9(1939).—It has been known for some time that the presence of considerable AgCl ppt. can cause appreciable error in the titration of Ag^+ with CNS^- by the method of Volhard. To avoid adsorption effects it has been recommended to filter off the ppt. before titrating the excess Ag^+. It is possible, however, to prevent the error by adding a protective colloid. Thus the addn. of 10 ml. of a 4% soln. of thymol in ether or amyl alc. proved satisfactory in titrating about 1 milliequiv. of Cl^- in approx. 30 ml. of soln. Good stirring is essential during the titration. The adsorption of Ag ions can also be prevented by titrating in the presence of HNO_3 and NH_4NO_3. This also helps in the gravimetric detn. of Cl^-. W. T. H.

Argentometric titration of the cyanide ion with diphenylcarbazone as indicator. Raluca Ripan-Tilici. *Z. anal. Chem.* **118**, 305–7(1939).—Diphenylcarbazone gives a violet compd. with Ag^+ and when a titration is carried out at pH = 4–4.4, the org. compd. can be used to indicate the presence of excess Ag^+ when the end point is reached. In some cases, as with AgCN and AgSeCN, the violet color appears too soon in acid solns. If the titration is carried out at pH = 9–12, the ppt. is colored blue and the violet color of the soln. disappears as soon as the end point is reached. The pseudohalides, CN^-, SCN^-, $SeCN^-$ and also SeO_3^{--}, can, with the exception of $SeCN^-$, be titrated with the blue color of the ppt. taken as the end point. With $SeCN^-$ the blue color of the ppt. is obtained continuously in a basic soln. To titrate CN^- the following procedure is recommended: To the soln. at pH = 9–10 add 4 drops of 0.3% diphenylcarbazone soln. in EtOH. The indicator will show a reddish brown color. Add $AgNO_3$ soln. and shake to help make the ppt. redissolve in the excess CN^-. As soon as all CN^- has been converted into $[Ag(CN)_2]^-$ the next drop of Ag^+ causes pptn. of a little AgCN and the indicator changes to violet. Then, when just as much more Ag^+ ion has been added and all the Ag is pptd. as AgCN, the ppt. suddenly turns blue and coagulates. To obtain good results the alkali cyanide soln. to be titrated should be 0.1–0.5 *M* and the Ag^+ soln. used should be of similar strength. The diphenylcarbazone shows the violet color when the ratio 2 CN:1 Ag prevails and the blue color of the ppt. is obtained at 1 CN:1 Ag. The results of 9 titrations showed excellent concordance at both end points. W. T. H.

Sensitivity of the test for lead and sulfide ions by means of the formation of $[(PbBr)_2S]$. Z. Karaoglanov. *Z. anal. Chem.* **118**, 311–22(1939).—If sep. solns. of Pb^{++}, HCl or HBr and H_2S are mixed, a ppt. results which may be black, red or yellow. The red compd. $PbS.PbBr_2$ is quite stable. The formula can also be written $[(PbBr)_2S]$. Its intense color can be used for the detection of Pb or H_2S and when the red color is used there is less danger of interference from other metal ions than when the test for Pb or H_2S is based on the formation of PbS. The sensitivity of the test depends largely upon the concns. of HBr and of H_2S. Carried out in a test tube with 10 ml. of soln. the sensitivity varies from 59.2 to 592 γ of Pb in 10 ml. The test will serve to detect 8–12 γ of Pb if the soln. is treated with HBr soln., evapd. to dryness and the residue is moistened with HBr soln. and treated dropwise with H_2S water. Another method which permits the detection of even less Pb consists in moistening filter paper with the soln., then with HBr soln. and finally with drops of H_2S water. Cu, Bi, Cd, Sb and Sn interfere. W. T. H.

Volumetric determination of the nickel ion with potassium cyanide in the presence of diphenylcarbazone as indicator. Raluca Ripan-Tilici. *Z. anal. Chem.* **118**, 308–10(1939).—A freshly prepd. soln. of KCN to which 3–4 drops of 0.3% diphenylcarbazone in EtOH has been added can be titrated with a neutral soln. of Ni^{++}. The procedure can be used for detg. Ni^{++} or conversely for detg. CN^-. As long as the soln. contains free CN^- anions, the Ni is present as $[Ni(CN)_4]_2^{--}$ anion but when more Ni is present $Ni(CN)_2$ is formed and an intense pink color results. An appreciable quantity of the $Ni(CN)_2$ remains in soln. as $[Ni(CN)_2]$ but the end point is accurate. The titration should take place fairly rapidly and the KCN soln. should be 0.05–0.01 *M* and freshly prepd. W. T. H.

Potentiometric titration of the stannous ion with potassium iodate. G. Spacu and C. Drăgulescu. *Bull. sect. sci. acad. roumaine* **20**, No. 1–3, 1–16(1938).—Solns. of $SnCl_2$ in 1.21 *N* HCl were titrated successfully under N_2 with 0.01 *M* KIO_3. About 25 mg. was present and the total vol. was about 40 ml. at the end of the titration. The values agreed within 0–0.6% of the truth which is satisfactory in detg. small quantities of Sn. The method was good in the presence of other elements likely to be found in alloys. W. T. H.

Potentiometric titration of the stannous ion with alkali hypoiodite. G. Spacu and C. Drăgulescu. *Bull. sect. sci. acad. roumaine* **20**, No. 8–10, 1–10(1938).—The titrations described were made with approx. 0.03 *M* $SnCl_2$ in 1–1.2 *N* HCl and one of I_2 in KI which was 0.01 *N* in I_2 and 6 *M* in KI. A measured vol. of the $SnCl_2$ soln. (1.0–10.0 ml.) was run into an excess of *M* NaOH and titrated in an atm. of N_2 with the I_2 soln. The titration was followed potentiometrically in the usual way. Under the above conditions, Na_2SnO_2 is formed which reacts with the NaIO (formed by the action of I_2 on NaOH) and the products are Na_2SnO_3 and NaI. The equivs. of Sn and I_2 are the same as if the reaction took place in an acid soln. The max. error in 13 titrations, for which all the potentiometer readings are given, was

4.624 ml. used in place of 4.654 ml. calcd. About 30 min. was required for a titration. W. T. H.

Lead poisoning. Precision method for extremely small amounts of lead. Frederick L. Smith, 2nd. *Penna. Dept. Labor Ind. Safe Practice Bull.* No. 52, 8 pp.(1939). —A lecture in which the literature of methods for detg. traces of Pb is reviewed and the method in use at the Jefferson Medical College Hospital at Philadelphia is described. The method is the colorimetric detn. of Pb with dithizone. 78 references. W. T. H.

Current review of the literature of microchemical work. Edith Nadler. *Mikrochemie* 28, 82–112(1939); cf. *C. A.* 33, 5771[4]. W. T. H.

Survey of methods and apparatus for micro gas analysis. H. Hartridge. *J. Sci. Instruments* 16, 317–24(1939).—A review of the following chem. and phys. methods: dry gas, variable vol.; moist gas, variable vol.; diver method; mica-plate method; spectroscopy; thermal cond.; dielec. const. 18 references. W. F. Bruce

Microchemical elementary analysis (determination of carbon, hydrogen and nitrogen). C. Tiedcke. *Mikrochemie* 28, 64–81(1939)(in German).—Several innovations in the detn. of C, H and N are described. The use of ascarite and drierite for the absorption of CO_2 and H_2O, resp., is regarded as the greatest improvement since the adoption of the technique described by Pregl. The use of a furnace heated electrically is also a marked improvement over the gas-fired furnace. For the detn. of C and H, the use of a com. cylinder of O_2, with the aid of a suitable reduction valve, makes the use of a tank of O_2 under 1 atm. pressure unnecessary. The preheating of the O_2, for the purpose of purification, is advised strongly. For the combustion a temp. of 600–700° is advised. For heating the PbO_2 a glass vessel contg. boiling decalin is preferred. Full directions are given for carrying out the detns. of C, H and N and although personal preferences are indicated the different tastes of different operators are taken into consideration. W. T. H.

Colorimetric microdetermination of copper. Isamu Numata and Danzi Matukawa. *J. Biochem.* (Japan) 30, 395–9(1939).—Measure 1 cc. of soln. contg. less than 6 γ Cu into a small separatory funnel, dil. to 5 cc. with H_2O and add 1 cc. of 10% H_2SO_4 and 3 cc. of dithizone reagent and shake for 5 min. (The dithizone reagent is prepd. in the following manner: Dissolve 10 mg. dithizone in 50 cc. CCl_4, transfer to a separatory funnel, add an equal vol. of dil. NH_4OH (1:200) and shake vigorously. The dithizone passes into the aq. phase. Add 50 cc. CCl_4 to the water soln., then 25 cc. 1% H_2SO_4 and shake again. The CCl_4 phase becomes colored a beautiful green. Wash the CCl_4 soln. several times with water, and place in a brown bottle under a layer of 25 cc. of a 12% soln. of $Na_2SO_3.7H_2O$ in *N* H_2SO_4. In this condition the reagent can be kept almost indefinitely in the refrigerator.) With amts. of Cu less than 4 γ, the CCl_4 becomes dark green, with 6 γ dark violet, but when the color is red-violet it indicates that the Cu is in excess of reagent. Transfer the CCl_4 soln. quantitatively to a new separatory funnel and shake 2 min. with 4 cc. of the dil. NH_4OH, and discard the latter. These washings are repeated 7 times. Finally, add 5 cc. 1% H_2SO_4 to the CCl_4 soln. and shake for 1 min. In the presence of Cu this will be colored violet, while the blank will be water-clear. Filter the CCl_4 soln. into a test tube and make up to 5 cc. with CCl_4. The reading in the photometer (using a 5-mm. cell and filter S55) must be made within 10 min. The calcn. is made by means of the equation $16 \times E/a = x$ in γ per cc., where E is the extinction coeff. and a the quantity of original soln. employed. S. Morgulis

New microchemical test for lead as cesium lead iodide, $CsPbI_3$. H. Jurány. *Mikrochemie* 28, 14–22(1939)(in German).—The test is best accomplished by adding KI crystals until any yellow PbI_2 formed is redissolved to $KPbI_3$. Then a little CsCl is added and a greenish yellow cluster of needles is formed. Unfortunately the ions of Sb, Bi, Sn and Cu interfere but it is easy to isolate the Pb as sulfate before applying the test. As little as 0.01 γ Pb can be identified. W. T. H.

Microdetermination of organic carbon in the wet way. Ed. F. Degering and T. Z. Ball. *Ind. Eng. Chem., Anal. Ed.* 12, 124–5(1940).—A Hg-bead dilatometer is used to measure the CO_2 evolved during oxidation by CrO_3 in H_2SO_4. A sample of 2.5–3.0 mg is weighed in a glass capsule and inserted in a two-leg reaction vessel, the other leg of which contains the oxidizing mixt. After 10-min. allowance for temp. equil., the materials are mixed and heated at 85° for 2 hrs. and allowed to cool. The percentage of C is calcd. directly from the change in vol.
Wm. E. Trout, Jr.

Ash in organic compounds. Determination by microtechnique with automatic combustion. A. R. Norton, G. L. Royer and R. Koegel. *Ind. Eng. Chem., Anal. Ed.* 12, 121–3(1940).—The Pregl method of combustion is adapted for the detn. of ash. Samples of about 150 mg. are weighed in Pt boats in Coomgs-Alber Pt cylinders. O_2 is passed over the sample in a quartz tube which is moved slowly through an elec. furnace by means of a phonograph motor and gear. The max. temp. is about 800°. Two samples can be ashed simultaneously in parallel tubes. The method is as accurate as the macro method using a muffle furnace and requires 1/5 to 1/14 the time. Wm. E. Trout, Jr.

Colorimetric microdetermination of formaldehyde. Danzi Matukawa. *J. Biochem.* (Japan) 30, 385–94 (1939).—Add to 2.0 cc. of a H_2CO soln. (0.02 to 1.0 mg. % concn.) 1 cc. of 8% NaCl and 1 cc. of a 0.5% phenylhydrazine-HCl in 50% alc. Mix well and leave in a water bath at 40° for 5–10 min. Add 0.5 cc. of the $K_3Fe(CN)_6$ reagent and mix. (The latter is prepd. by dissolving 2.5 g. $K_3Fe(CN)_6$ in 50 cc. H_2O, adding 40 cc. abs. alc. and dilg. to 100 cc. It should be kept in a dark bottle). Follow up the reagent immediately with 0.75 cc. HCl and place in water at 15° for 10 min., when a red color will develop. Examine the color in the step photometer, with light filter S53 and the 5 mm. cell. The extinction coeff. remains unchanged for about 40 min. The reaction is highly specific. The alteration of the H_2CO content of toxin solns. transformed to toxoid has been detd. and the results were compared with the detn. by preliminary pptn. with starch. S. Morgulis

Simultaneous microdetermination of various fractions of lipides (phospholipide, cholesterol and fat) together with the determination of their iodine number. Morio Yasuda and Korenori Ono. *J. Biochem.* (Japan) 30, 401–21(1939). Each lipide fraction is separately pptd. for the detn., each new fraction being obtained from the residue. This procedure permits working with small quantities. The following scheme of sepn. is used: Evap. the alc.-ether ext. (100–150 cc.) to dryness, and ext. the residue several times with 10 cc. petroleum ether. Conc. the latter to about 15 cc. and centrifuge for 5 min. Evap. the supernatant ether in a centrifuge tube to 2 cc., add 7 cc. acetone and a drop of a satd. alc. soln. of $MgCl_2$. Sep. the pptd. phospholipide by centrifuging, wash with 5 cc. acetone and transfer the acetone soln. to a 100-cc. flask (I). In the latter ppt. the cholesterol with 0.5% alc. digitonin, the amt. of reagent being adjusted to the expected quantity of free cholesterol. Evap. the contents of flask I. Add to the dry residue about 10 cc. of acetone-H_2O (1:1) and heat a few min. on the water bath to dissolve the excess digitonin. Pour through a glass filter to collect the digitonide, and wash with acetone and ether. Collect the filtrate and washings in flask II and evap. to dryness. Add 1–2 cc. glacial AcH and heat until dissolved, and ppt. the digitonin with a ten-fold amt. of ether. Filter off the pptd. digitonin after 30 min., evap. the filtrate, dissolve the residue in 15 cc. alc., add 0.2 cc. satd. KOH and saponify for 20 min. on a water bath. Cool, neutralize with dil. HCl (1:4), ppt. the liberated cholesterol with an alc. digitonin soln. and evap. to dryness. Again dissolve the excess digitonin with dil. acetone, filter off the cholesterol digitonide and wash with acetone and ether. Collect the combined filtrate and washings consisting of fatty acids in flask III and evap. to dryness. Treat the residue with

1 cc. glacial AcOH and ten-fold the amt. ether to ppt. excess digitonin. Evap. the filtrate again to dryness on the water bath, dissolve in about 5 cc. alc. and make alk. with a few drops satd. KOH. Boil off the alc. and heat the residue with 10–15 cc. H_2O to dissolve the soaps. Cool, ppt. the fatty acids by addg. 0.5–1 cc. H_2SO_4 (1:1) and leave in ice box for 1 hr. Collect the fatty acids on a glass filter and wash with small amts. of ice-cold H_2O until free from acid. Detailed instructions are given for the detn. of each of the sepd. fractions (phospholipide, free and bound cholesterol, and fatty acids). The neutral fat content is calcd. from the fatty acids corrected for the amt. bound to cholesterol. The detn. of the I no. of fatty acids is also discussed. S. Morgulis

Scheme for the microchemical separation of some toxicologically important alkaloids. W. F. Whitmore and C. A. Wood. *Mikrochimie* **28**, 1–13(1939)(in English); cf. *C. A.* **34**, 53[1].– The scheme is useful for detecting about 20 of the most important narcotic alkaloids when the total quantity present ranges from 0.5 to 3 mg. in 1 ml. If only one alkaloid is present, less than 0.5 mg. can be isolated and identified and in some cases, e. g., morphine, it is possible to sep. less than 0.5 mg. from a mixt. of several bases. The alkaloids are divided into 4 groups. Group I consists of weak bases of which the salts are hydrolyzed considerably. The group includes narcotine, caffeine, papaverine and theobromine. A little water and a drop of 30% H_2SO_4 are added to an unknown mixt. and Group I is removed by extg. 3 times with 0.5-ml. portions of $CHCl_3$. The ext. is evapd. in a 2-ml. centrifuge cone and tested with a drop of dil. H_2SO_4 and Br_2 in KBr soln. If only 1 alkaloid of the group is present, the appearance of the turbidity produced will often serve to identify it. Treatment with satd. borax soln. serves to sep. caffeine and theobromine which are sol. in borax soln. and narcotine or papaverine is not. Both caffeine and theobromine are identified eventually by the test with Br_2 in KBr soln. By heating with addnl. borax soln. narcotine can be dissolved and identified by the crystals which sep. on adding acid. Papaverine is undissolved by borax soln. and identified by dissolving in dil. HCl and pptg. with CdI_2. Group II contains brucine, strychnine and quinidine. They are pptd. by adding NaI to a dil. aq. soln. of the salts after the removal of Group I. Quinidine is isolated by adding dil. NaOH to the iodides and by extg. with ether. The HCl soln. is treated with K anthraquinone sulfonate and the crystals are studied. Extn. of bases with $CHCl_3$ and treatment with HCl and Na chlorosmate serve for the identification of strychnine and brucine. The strychnine and brucine are sepd. by treatment with dil. HCl and $K_4Fe(CN)_6$ and strychnine is found in the centrifuged ppt. by the $HSbCl_4$ test. Brucine is identified by the reaction with $BiCl_3$. Group III consists of quinine, cinchonidine, cinchonine, morphine, cocaine and stovaine which are pptd. after the removal of Groups I and II as free bases from aq. soln. by the addn. of satd. $NaHCO_3$ soln. The ppt. is dissolved by a little 0.1 *N* HCl and the quinine and cinchonidine are pptd. by means of 20% Na tartrate soln. After treatment with NaOH, extn. with ether and evapn., the residue is dissolved in dil. H_2SO_4 and the quinine is pptd. and identified by its appearance or by dissolving in dil. HCl and treating with H_2PtCl_6. The cinchonidine is detected by the Na_2SnI_4 test. After the above removal of quinine and cinchonidine, an excess of NaOH soln. is added and an extn. made with petr. ether. Cocaine and stovaine dissolve; the former is detected by means of Na_2PtBr_6 and the latter by the $HAuBr_4$ reaction. Cinchonine is eventually identified by the test with K_2PtI_6 and morphine by the K_2HgBr_4 reaction. Group IV contains heroine, procaine, β-eucaine, nicotine, dionine, codeine and atropine. After the removal of Group III, an extn. is made with $CHCl_3$ and then codeine, dionine, β-eucaine and procaine are pptd. with NaBr and the heroine, nicotine and atropine left in soln. After suitable sepns. procaine is identified as its Br substitution product, β-eucaine by the reaction with Na_2PtBr_6 and so is dionine. Codeine is identified by means of CdI_2, heroine by H_2PtCl_6 in 5% HBr, and atropine by treating with Br_2 in NaBr soln. Nicotine is identified by the test with $Co(NO_3)_2$ and NH_4SCN. W. T. H. 1

The physical chemistry of alcohol distillation for forensic determinations. S. Wehrli. *Deut. Z. ges. gerichtl. Med.* **31**, 233–8(1939).—A constant "*K*" varying for each impurity, was found to be directly proportional to the ease with which it may be detected in and sepd. from the alc. Frances Krasnow

New method for the direct determination of oxygen in organic substances. Max Schütze. *Z. anal. Chem.* **118**, 245–58(1939).—The method consists in decompg. the substance thermically, leading the "cracked" products over C which is heated to 1000° in a stream of pure N_2. Then, at room temp., the CO_2 is oxidized with I_2O_5 and the CO_2 is collected in an absorption tube contg. P_2O_5, pumice and soda-asbestos. The app. and the procedure are described in detail, and, although no actual results are given, the statement is made that the method has been in use since 1936 and found satisfactory. W. T. H. 2

Microanalytical procedure for the direct determination of oxygen in organic substances. Wilhelm Zimmermann. *Z. anal. Chem.* **118**, 258–63(1939).—The procedure of Schütze (cf. preceding abstr.) was designed for semimicro work. An adaptation of the method with microchem. app. shows that with about 5 mg. of benzoic acid, salicylic acid, nitraniline, chloranil or sulfanilic acid, results can be obtained which are within 1% of the truth, e. g., 26.40 instead of 26.21% O. W. T. H. 3 4

Volumetric and colorimetric methods for the determination of acetylene in air. M. V. Nifontova. *Org. Chem. Ind.* (U. S. S. R.) **6**, 457–9(1939).—The volumetric detn. is based on the reaction in the presence of excess NH_4OH: $2AgNO_3 + C_2H_2 + 2NH_4OH = Ag_2C_2 + 2NH_4NO_3 + 2H_2O$ and depends on the titration of excess $AgNO_3$ in the filtrate. To 2 ml. of 0.01 *N* $AgNO_3$ add 3 drops of concd. NH_4OH and a measured vol. of the C_2H_2 in H_2O; shake well until the soln. becomes clear, filter and wash the ppt. with H_2O. Make the soln. acid with HNO_3, add 1 ml. of ferric alum soln. as indicator and titrate from a microburet with 0.01 *N* NH_4SCN. Make a blank test. The difference between the 2 detns. gives C_2H_2. The colorimetric detn. of very small quantities of C_2H_2 (a few thousandths of 1 mg.) is based on the reaction in a neutral soln.: $C_2H_2 + 3AgNO_3 = Ag_2C_2 \cdot AgNO_3 + 2HNO_3$). The HNO_3 in the filtrate is detd. by making up the soln. to a definite vol., adding 1 drop of 0.2% methyl red and comparing with standard HNO_3 solns. similarly treated. Chas. Blanc 5 6

Determination of dichloroethane vapors in air. F. F. Mel'nikov and B. V. Senilov. *Lab. Prakt.* (U. S. S. R.) **14**, No. 9–10, 18–20(1939).—A soln. of $Hg(NO_3)_2$ was added (1 ml. of which was equiv. to 0.5 mg. of Cl^-) until an intensive Tyndall cone was obtained. A correction table prepd. on the basis of titration data with $HgCl_2$ at different concns. was used. Take the air sample according to the method of Ginzburg (cf. *C A.* **33**, 4909[1]) by absorption with alc. Transfer the contents of the 3 absorbents into a flask, wash with 15 ml. of alc., add the wash liquid to the flask, add 20 ml. of satd. Na alcoholate soln. or a corresponding amt. of metallic Na (according to Stepanov), heat the mixt. for 2 hrs. under a reflux condenser (a parallel control expt. is performed under the same conditions with 50 ml. of alc. and 20 ml. of satd. Na alcoholate soln. or a corresponding amt. of metallic Na); after having removed the reflux condenser distil off the alc., dissolve the dry residue in 20 ml. of water, neutralize with concd. HNO_3 (free from Cl^-) until a definite acid reaction is obtained with litmus paper, filter through a glass filter into a cone-shaped 100-cc. graduated flask, wash the filter several times with small portions of distd. water, bring the filtrate to 100 ml., add 1 ml. of HNO_3 (1:5) + 1 ml. of 10% $Na_2[Fe(CN)_5NO]$ soln. and titrate the sample and the control soln. with a $Hg(NO_3)_2$ soln. from a microburet. The Cl^- content is recalcd. to dichloroethane. From samples contg. 0.071, 0.142, 0.214, 0.286 and 0.409 the following results were obtained, resp.: 0.069, 0.144, 0.220, 0.279 and 0.411 mg. of Cl^-/100 ml. of soln. Seven references. W. R. Henn 7 8 9

Determination of formaldehyde. II. New method with ammonia. Arnaldo Foschini and Mario Talenti. *Z. anal. Chem.* **118**, 94–7(1939); cf. *C. A.* **33**, 7238³.—The following modified procedure has been found satisfactory. Place 8 ml. of the soln. (accurately measured) in a 150-ml. Erlenmeyer flask, add 35 ml. of 2 *N* NH_3 soln., shake and after standing a little while, distil off the excess NH_3, under reduced pressure, into 15 ml. of *N* H_2SO_4. Titrate the excess acid and from this calc. how much NH_3 was taken up by the aldehyde to form $(CH_2)_6N_4$. The results agree well with those obtained by the H_2O_2 method but are higher than the values obtained by direct titration of the excess NH_3 (without distn.), to a rosolic acid end point. W. T. H. 1 2

Detection of diazotizable amino groups by the drop method. S. I. Burmistrov. *Org. Chem. Ind.* (U. S. S. R.) **6**, 328(1939).—Place 1–2 drops of an Et_2O or Me_2CO soln. of the compd. to be tested on a strip of filter paper (3 cm. wide), allow to dry and insert the paper into a flask above a layer of concd. HCl for 5 min. Expose the paper strip to the fumes of freshly prepd. $EtNO_2$ (EtOH + HCl and a few $NaNO_2$ crystals) for 5 min. Cross the drop spot with a streak of an Et_2O soln. of *N*-phenyl-2-naphthylamine, 2-naphthol (I) or resorcinol (II). If I or II is used, expose the paper to NH_3 fumes. Wet the paper by breathing or exposing to water vapors. Orange, red or violet color indicates the presence of a diazotizable NH_2 group in the compd. The method cannot be applied to tertiary aryl amines because their diazonium salts and azo compds. give nearly identical color reactions. Chas. Blanc 3 4

Quantitative drop analysis. XI. Determination of lactic acid. R. M. McCready, H. K. Mitchell and P. L. Kirk. *Mikrochemie* **28**, 23–9(1939)(in English); cf. *C. A.* **32**, 3291⁷.—The procedure described is an adaptation of a method which has been used for detg. larger quantities of lactic acid. The basic techniques necessary for titrating, distg., deproteinization, etc., have been developed for this analysis so that samples contg. 1.22 to 28.75 γ of lactic acid can be tested with satisfactory precision. The lactic acid is oxidized to AcH by boiling with an acid soln. of $KMnO_4$ in the presence of Mn^{++}. The aldehyde is aerated and distd. through a reflux condenser into $NaHSO_3$ soln. The excess bisulfite is removed with I_2 and the bisulfite compd. of the aldehyde detd. by titration with I_2 after treatment with $NaHCO_3$. W. T. H. 5 6

Identification of sugars and of mannitol. E. A. Beloruchev. *Lab. Prakt.* (U. S. S. R.) **14**, No. 9–10, 10–11 (1939).—On the basis of the characteristic properties of glucose, fructose, arabinose, sucrose, lactose, maltose and mannitol a table has been prepd. by means of which any of these substances can be identified. The properties which are considered are the reaction to Fehling's soln., the reaction to Barfod's reagent (13.3 g. of Cu acetate dissolved in 200 cc. of a 1% soln. of AcOH), the reaction to Fehling's soln. after inversion, the characteristics of the obtained osazones and the polarization of the substances. Three references are given. W. R. Henn 7

Color reactions between sodium nitroprusside and cyclic hydrocarbons. Gino Scagliarini and Elio Lucchi. *Boll. sci. facoltà chim. ind., Bologna* **1940**, No. 1–2, 58–9.—In continuation of previous investigations (cf. *C. A.* **31**, 7421⁷) color reactions of Na nitroprusside with indene (I), cyclopentadiene (II), propenylbenzene (III), allylbenzene 3,4- (IV) and 1,4-dihydronaphthalene, dihydroanthracene (V), anthracene, phenanthrene, fluorene, acenaphthene, cyclohexene, biphenyl, naphthalene and retene were studied, generally in MeOH soln. made slightly basic with KOH or NaOH. I and II gave an intense red coloration and a red ppt. III, IV and V gave a very weak reaction. The other compds. gave no particular coloration. The difference in the behavior of the compds., which are all able to add alkali metals, is discussed. The analytical results of the complex with I correspond with the formula $K_3[Fe^{II}(CN)_5NOC_9H_7]$. Dora Stern 8

Detection and determination of picrolonic acid. Sinogu Hukuda. *J. Biochem.* (Japan) **30**, 465–71(1939).—When picrolonic acid is heated slowly it undergoes a condensation, 2 mols. uniting with the loss of 2 NO and H_2O, giving a cryst. substance $C_{20}H_{14}N_6O_7$, with sharp m. p. at 170°. Treated with NaOH it yields a deep red color, proportional to the amt. of picrolonic acid. The reaction is sensitive to a dilu. 1:1,000,000 and is very specific. To carry out the test, first free the picrolonic acid from picrolonates by acidifying with H_2SO_4 and extg. with ether. Evap. the ether ext. to dryness and gradually heat the residue to 125° and keep at this temp. for 1 hr. Dissolve the residue in *N* NaOH and dil. to 10 cc. Prepare the standard soln. for matching the color by dissolving a weighed portion of the substance in $CHCl_3$. Evap. aliquots of this soln. to dryness and take up in 10 cc. *N* NaOH. Always use a standard which nearly matches that of the unknown sample. S. Morgulis 9

Analysis of benzyl chloride. G. S. Tsypin and A. I. Chekalina. *Org. Chem. Ind.* (U. S. S. R.) **6**, 504–6 (1939).—If com. $PhCH_2Cl$ (I), contaminated by higher Cl derivs., is boiled 2 5–3 hrs. in H_2O, I is quantitatively hydrolyzed to $PhCH_2OH$, $PhCHCl_2$ (II) to BzH and $PhCCl_3$ (III) to BzOH. BzOH and the HCl formed in the reaction are detd. in the soln. by titration with KOH in EtOH and phenolphthalein or methyl blue. The partial oxidation of the BzH during the hydrolysis is completely prevented in the presence of a little hydroquinone. Place 0.5 g. of I in a Schimmel flask (having a conical bottom and connected by a ground-in joint with an upright air condenser), neutralize with aq. 0.03 *N* KOH to phenolphthalein, add 1 ml. of 0.05% hydroquinone and 20 ml. H_2O and boil 2.45 hrs. in the elec. air bath. Flush the condenser with 20 ml. of neutralized EtOH (free from CO_2) and det. the total acidity by titration with 0.1 *N* KOH in EtOH and the indicator. Add to the soln. a few drops of $K_2Cr_2O_7$ soln. and titrate with 0.1 *N* $AgNO_3$ to a faint coloration. Det. BzH by the method of Stewart and Donnally (*C. A.* **26**, 5479) by iodometric titration of the excess of $NaHSO_3$ added to the soln. to form the bisulfite compd. Formulas are given for calcg. I, II and III from the results of analysis. Chas. Blanc 10

Rapid determination of bornyl chloride in pinene saturated with hydrogen chloride. V. I. Lyubomilov. *Org. Chem. Ind.* (U. S. S. R.) **6**, 326–7(1939).—In the production of bornyl chloride (I) from pinene and HCl, I can be roughly detd. by alternate cooling at 12° and filtering of the reaction mixt. until the filtrate forms no ppt. The wt. of ppt. gives I. Chas. Blanc 11

Determination of some war gases in samples of soil. C. J. de Wolff. *Pharm. Weekblad* **76**, 1612(1939).—Chloroacetophenone: Heat 10 g. sample of soil with 5 cc. EtOH and filter. To 1 cc. of the filtrate add 5 drops of water and 0.5 g. KI. Add 1 cc. of 10% NH_4OH and then add 0.1 *N* I until the yellow color persists. Other aliphatic ketone tests can be used. Adamsite (Ph_2AsCl): To the filtrate add an equal vol. of a 1% soln. of NaCl in 1% HNO_3. Filter if necessary. Add concd. H_2SO_4 (ring test). The appearance of a blue ring indicates Ph_2NH. Felix Saunders 12

A simple and rapid method for determining nicotine. A. Verda and E. Herzfeld. *Z. anal. Chem.* **118**, 9–13 (1939).—Take 5 g. of tobacco and distil with steam into a receiver contg. 3 g. of gum arabic. Stop distg. after obtaining 300 ml. of distillate. Mix and take two 5-ml. portions in sep. tubes. To each add 5 ml. of 1% gum arabic soln. From the 2nd tube pipet off 5 ml. of soln. and to this add 5 ml. of gum arabic soln and continue in this way until a series of tubes is obtained, each representing half as much of the sample as the previous one. To each tube add 0.5 ml. of silicotungstic acid reagent and see when the appearance of opalescence stops. As little as 0.31 mg. of nicotine suffices to give the test. By comparing with standards good results can be obtained. W. T. H. 13

Analysis of gas mixtures. M. S. Gershenovich, G. F. Daletskiĭ and N. Z. Kotelkov. Russ. 52,083, Oct. 31, 1937. The gases are selectively oxidized over a catalyst prepd. according to Russ. 50,659 by pptg. a Pt salt on an oxidized surface of a Ni-Cr alloy and reducing.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

ARTHUR M. BRANT

Brilliancy of transparent precious stones. W. Fr. Eppler. *Fortschr. Mineral. Krist. Petrog.* **23**, 1-40(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 285-6.—The relative importance for brilliancy of absorption, luster, refraction, total reflection, dispersion and scintillation is discussed with reference to the best method of cutting various stones. Refraction is shown to be the most important. Ideal methods of cutting 22 varieties are given. C. A. Silberrad

White gem-stones with bluish opalescence. Marie Therese Mackowsky. *Deut. Goldschmiede-Ztg.* **41**, 335 6 (1937); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 579.—Some amethysts on heating above 560° turn white with an opalescent shimmer. They are then termed commercially "white topaz." The more correct name "white amethyst" is suggested. The means of distinguishing them from other similar stones, e. g., milky quartz, by means of d., *n* and H are detailed. C. A. Silberrad

Röntgenographic study of $MgHPO_4.7H_2O$ (phosphorrösslerite). G. Hägele and F. Machatschki. *Zentr. Mineral., Geol.* **1939A**, 297-300; cf. Friedrich and Robitsch, *C. A.* **33**, 5777[4].—Weissenberg photographs give $a = 11.35$, $b = 25.36$, $c = 6.60$ A., β approx. 95°, with 8 mols. of $MgHPO_4.7H_2O$ in the unit cell. $a:b:c = 0.4475:1:0.2605$. The space group is probably C_{2h}^5, but the structure is not identical, as might have been supposed, with that of $FeSO_4.7H_2O$. Michael Fleischer

The distribution of indium in Finnish minerals and its separation from other metals. Olavi Erametsä. *Ann. Acad. Sci. Fennicae* **A51**, No. 1, 92 pp.(1938)(in German).—The In content of 32 important Finnish minerals was detd. with a Zeiss three-prism-glass spectrograph with the use of the Cu arc. The procedure is given in detail, as well as a discussion of the effects of interfering elements. Flotation expts. with ore from the Pitkäranta region showed that the In was present both in zinc blende and in another In-bearing mineral. Spectral analysis was used to follow the concn. of In in the residues and to identify the In in the ppts. The prepn. of In oxide is described in detail. George Ayers

Oriented inclusions of staurolite, zircon and garnet in muscovite. Skating crystals and their significance. Clifford Frondel. *Am. Mineral.* **25**, 69-87(1940).—Staurolite, zircon and garnet were deposited on the (001) of the mica from suspension; statistically, preferred orientations occur at crystallographic positions in which directions of relatively low index in the planes of contact of the inclusions and the muscovite coincide. C. H. H.

Spectral analytical investigations and luminescence observations on fluorite and apatite. Herbert Haberlandt. *Mitt. Inst. Radiumforsch.* No. 414, in *Sitzber. Akad. Wiss. Wien, Math. naturw. Klasse*, Abt. IIa, **147**, 137-50 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 241-2; cf. *C. A.* **31**, 8452[6].—Further spectral analytical examn. of various fluorites and apatites exhibiting marked fluorescence or thermoluminescence and comparison with the spectra of artificial prepns. contg. Mn, Yb and Y show that the central portion of crystals of Spitzkoppe fluorite is a yttrofluorite contg. about 10% of Y, while the green outer portion contains at most 1% Y and 0.1% Yb. (The method used, however, is somewhat insensitive to Sm, Tb, Dy and V.) In similar fashion in various samples of apatite amts. of Y, Yb and Mn of the orders, resp., of 0.1, 0.01 and 0.001-1.0% were proved and frequently also Fe, and occasionally Ce, As and (or) V. In apatite from Juanilla As (up to 0.22%) and V were found. C. A. S.

Synthetic stibnite and bismuthinite. E. Abbolito. *Periodico mineral.* (Rome) **9**, 77-83(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 80.—The optical properties (color, pleochroism, reflecting power, etc.) of synthetic stibnite and bismuthinite are identical with those of the natural crystals; only the anisotropic effects are stronger than in the natural crystals. C. A. Silberrad

Crystallographic examination of Hungarian pyrite. L. Tokody. *Math. és természettudományi Közlemények* **38**, No. 2, 1-55(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 525-8.—The various crystal forms (many new) of pyrite occurring at 20 different Hungarian localities are described, with in many cases the minerals with which the pyrite is assocd. C. A. Silberrad

Miargyrite crystals from Randsburg, California. Joseph Murdoch. *Am. Mineral.* **24**, 772-81(1939).—A total of 47 forms was observed; 313 and 322 were new, forms 233 and 205 were confirmed. C. H. Hale

Specularite -alunite mineralization at Hickeys Pond, Newfoundland. Arthur L. Howland. *Am. Mineral.* **25**, 34-45(1940).—Quartz, alunite and specularite occur together in a silicified schist; alunite may average nearly 20% of the rock; the Fe content is about 3%. Mineralization took place along shear zones which paralleled the contact of granodiorite intrusive into greenstone. C. H. Hale

The lamellar structure of potash-soda feldspars. S. H. Chao and W. H. Taylor. *Proc. Roy. Soc.* (London) **A174**, 57-72(1940).—See *C. A.* **33**, 8531[9]. F. Gonet

Feldspars from crystalline spessartites. Rudolf Mosebach. *Senckbergiana* **20**, 346-63(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 566.—Analyses and optical properties of 6 potash feldspars from various pegmatites, kersantite and augen-gneiss, and of one plagioclase from pegmatite are compared, and their probable relations and origins discussed. C. A. Silberrad

Nephrite, carcaro and asbestos in the East Thuringian Vogtland schistose hills. Eberhard Rimann. *S. B. u. Abh. naturw. Ges. Isis* (Dresden) **1936/37**, 9(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 565; cf. *C. A.* **31**, 1325[4].—New occurrences of nephrite, cellular nephrite and carcaro in paleopicrite are described. Their formation has followed serpentinization of the ultrabasic magma by carbonate-contg. residual solns. C. A. S.

Green hornblende, asbestos, phlogopite, zircon and apatite from Lojane near Kumanovo. M. Tajder. *Bull. soc. sci. Skoplje* **18**, *Sect. sci. nat.* **6**, 193-200(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 135-6.—In the

chromite of the Lojane mine there occurs together with phlogopite, asbestos, zircon and apatite an emerald-green amphibole, which has n_α 1.6188, n_γ 1.6465, pleochroism light greenish brown and green, d. 3.042. Analysis of material sepd. from chromite by a soln. of d. 4.2: SiO_2 49.63, TiO_2 0.43, Al_2O_3 8.02, Fe_2O_3 0.10, Cr_2O_3 2.28, FeO 2.77, MgO 21.20, CaO 11.73, Na_2O 1.74, K_2O 0.16, H_2O+ 2.28%, corresponding with an isomorphous mixt. of 45% hornblende, 45% tremolite and 10% kupfferite. Complete analyses of the asbestos and phlogopite are also given. The apatite forms clear-green prisms up to 5 × 1 mm. C. A. Silberrad

Garnets and their role in nature. Lewis L. Fermor. *Indian Assoc. Cultivation Sci., Spec. Pub.* No. 6, 105 pp. (1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 684–6; cf. *C. A.* **32**, 7373[5].—The view is put forward that in addn. to the 6 usually recognized garnets there are 10 others, of which 4 are khoharite, $Mg_3Fe_2^{++}(SiO_4)_3$, skiagite Fe_3^{++}-$Fe_2^{+++}(SiO_4)_3$, calderite $Mn_3^{++}Fe_2^{+++}(SiO_4)_3$, and blythite $Mn_3^{++}Mn_2^{+++}(SiO_4)_3$, examples of which are described. A system of nomenclature is described, e. g., spandite (= spessartite + andradite). Possible methods of formation are discussed. C. A. Silberrad

A review of mineralogical investigations of tourmaline. T. N. Agafonova. *Trudy Tsentral. Nauch.-Issledovatel. Lab. Kamneĭ Samotsvetov Tr. "Russkie Samotsvety"* **1938**, No. 5, 62–70; *Khim. Referat. Zhur.* **2**, No. 5, 32 (1939).—A chronological review of all investigations of the crystallography, optic properties, pyroelectricity and chem. compn. of tourmalines from the 18th century to 1937. W. R. Henn

Stilbite in tonalite in Val Nambrone (Adamello group). Edoardo Sancro. *Periodico mineral.* (Rome) **9**, 205–12 (1938); *Neues Jahrb. Mineral., Geol.* Ref. I, **1939**, 266.—Yellow and yellowish white crystals of stilbite occur in druses in the tonalite of the Val Nambrone. They have d. 2.159, n_α 1.492, n_γ 1.501. Analysis: SiO_2 55.21, Al_2O_3 16.91, Fe_2O_3 trace, CaO 8.10, MgO 0.25, Na_2O 1.16, K_2O 0.45, H_2O 18.27%. A discussion as to the probable origin follows. C. A. Silberrad

Some zeolites from Erythrea. Antonio Scherillo. *Periodico mineral.* (Rome) **9**, 61–9 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 110–11.—Intergrown chabasite and thomsonite from Asmara, and stilbite (d. 2.14, n_α 1.499, n_γ 1.488), and scolecite (d. 2.275, n_α 1.510, n_β 1.516, n_γ 1.517) from Alomatà are described with complete analyses and dehydration curves. C. A. S.

Chlorites from a vein of auriferous quartz from Erythrea. Antonio Scherillo. *Periodico mineral.* (Rome) **9**, 71–6 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 102.—Analyses of 2 practically identical samples of chlorite from the auriferous quartz veins of Ugaro and Gola-Gul are given; they consist of amesite, strigovite and serpentine in the proportions 17:10.4. C. A. S.

Celadonite in an eruptive rock in Erythrea. Antonio Scherillo. *Periodico mineral.* (Rome) **9**, 253–64 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 105–6.—Celadonite occurs in druses in basaltic lava near Asmara. The druses are coated with zeolites, chiefly thomsonite and chabasite. The celadonite, pseudomorphous after olivine, is of a greenish yellow to greenish color and forms cryst. aggregates whose compn. indicates the formula $KMg_3Fe_2^{+++}Si_9O_{26}.nH_2O$. The dehydration curve shows the main loss of H_2O to occur at about 450°. C. A. S.

Synopsis of glauconitization. Zyun-iti Takahasi. *Recent Marine Sediments: a symposium, Am. Assoc. Petroleum Geol.* **1939**, 503–12.—A summary of work on the chem. compn., dehydration and origin of glauconite. George Ayers

Biotite-glauconite transformation and associated minerals. E. Wayne Galliher. *Recent Marine Sediments: a symposium, Am. Assoc. Petroleum Geol.* **1939**, 513–15. George Ayers

Some new mineral finds (dumortierite, scapolite) from the Kor Alps region, Styria and Carinthia. Heinz Meixner. *Zentr. Mineral., Geol.* **1940A**, 19–24.—Descriptive. Dumortierite was found as needles in scapolite crystals at Schwanberg, Styria. Scapolite, assocd. with tremolite, phlogopite and muscovite, occurs at Waldenstein, Carinthia. It is partly altered to montomorillonite. Michael Fleischer

A green zircon. J. Bolman. *Chem. Weekblad* **36**, 752–3 (1939).—An unusual variety of Ceylon zircon has phys. properties quite different from the other color varieties. In daylight its color is yellowish green, transparency is excellent, sp. gr. is 4.182 and n_ω 1.925, n_ϵ 1.984. N. B.

Heterogenetic polymorphism. Percy Quensel. *Geol. Foren. Forh.* **60**, 676–7 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 355–6.—Heterosite and Na purpurite, both $(Mn^{+++}, Fe^{+++})PO_4$, differ only in the proportions of Mn^{+++} and Fe^{+++}, and are produced by complete removal of alkalies from, and oxidation of the Mn^{++} and Fe^{++} in, triphylite and varulite, resp. The complicated structure of Na purpurite is probably to be explained as due to rearrangement consequent on removal of the large Na atom, removal of the smaller Li atom causing nothing of the sort. Such varying lattice structure due to differing chem. compn. of the original material is termed *heterogenetic polymorphism.* C. A. Silberrad

Chinglusuite. A new mineral. V. I. Gerasimovskiĭ. *Bull. acad. sci. U. R. S. S., Classe sci. math. nat., Sér. géol.* **1938**, No. 1, 153–6 (in English, 156–7); *Khim. Referat. Zhur.* **1**, No. 11–12, 66–7.—The mineral is found in the form of 0.5 cm. black opaque grains with a hardness of 2–3, a sp. gr. 2.151 and n = 1.582. It is easily dissolved in concd. HCl and in hot concd. HNO_3. A complete chem. analysis is given. According to G. the empirical formula of chinglusuite is $2(Na,K)_2O.5(Mn,Ca)O.3(Ti,Zr)O_2.14$-$SiO_2.9H_2O$. In its chem. compn. the mineral differs from all known titanosilicates but resembles neptunite and astrophillite. Al, Be, Sr, Sn and the rare earths were found spectroscopically. W. R. Henn

Stiepelmannite, a new mineral of the hamlinite group containing yttrium and rare earths. Paul Ramdohr and E. Thilo. *Zentr. Mineral., Geol.* **1940A**, 1–8; cf. *C. A.* **30**, 8082.—Small, highly lustrous crystals, observed in a pegmatite at Klein-Spitzkopje, German S. W. Africa, assocd. with beryl, topaz, phenakite, albite, quartz, microcline and yttrofluorite, were found to be a new mineral. Analysis gave SiO_2 0.29, rare earths (mol. wt. 326) 29.25, ZrO_2 1.12, CaO 0.50, Al_2O_3 30.83, H_2O 11.07, F probably present in small amt., P_2O_5 (by difference) 26.94. This gives the formula $(Y, Yb, etc.)PO_4.AlPO_4.2Al(OH)_3$, similar to the Ce mineral florencite. The mineral is rhombohedral, with α = 88°32′ and $a:c$ = 1.1.272. X-ray study gives a = 9.54 A. for the rhombohedral unit cell, which contains 4 mols. In the hexagonal setting a = 6.75, c = 16.52 A. The sp. gr. is 3.671 – 3.713; the hardness is approx. 6. Optically, stiepelmannite is pos., with n_0 = 1.695$_4$, n_ϵ 1.705$_4$. The basal cleavage is much less perfect than that of other minerals of this group, and the fracture is conchoidal. Michael Fleischer

Barite and stilpnosiderite from Rudabánya. E. Brummer. *Földtani Közlony* **68**, 68–71 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 135.—Two varieties of barite crystals are described. They occur on Cu-cuprite-malachite crystals, on limonite and with calcite in the heavy spar veins of the spathic Fe ore. Small quantities of stilpnosiderite were also observed, embedded in marcasite. C. A. Silberrad

Minerals newly reported from West Australia. Edward S. Simpson. *Ann. Rept. Chem. Branch, Mines Dept., West. Australia* **1937**, 12 pp. (1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 593; cf. *C. A.* **33**, 4915[4].—These include simpsonite and its weathering product metasimpsonite, beudantite, bindheimite, beidellite, triphylite, carminite and calciosamarskite. Analyses of 8 minerals and 4 rocks are given. C. A. Silberrad

Meteoritic iron phosphide. John D. Buddhue. *Popular Astron.* **46**, 282–5 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 293–4.—Examn. of some 70 analyses of schreibersite and rhabdite in most cases showed they had the compn. Fe_3NiP; in others there is probably solid soln. Lamellar intercalations are considered; thus in Fe from the Canyon Diablo a piece of schreibersite occurs in

kamacite with definite orientation. Such occurrences are called *Shepard-lamellae*. C. A. Silberrad

A test of the abundance of the heavy isotope of carbon in a graphite meteorite. F. A. Jenkins and Arthur S. King. *Publ. Astron. Soc. Pacific* **48**, 323–5(1936); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 293.—Spectroscopic examn. of the Edlen (Arizona) meteor (cf. Brady, *C. A.* **25**, 1462) shows the C contains the same proportion of the C^{13} isotope as Acheson graphite, i. e., 1% ± 0.1. The spectrum of many stars shows a greater abundance of it. C. A. S.

Meteoric iron of Agua Blanca. Enrique Herrero Ducloux and Ramón G. Loyarte. *Inst. museo univ. nacl. La Plata, Notas museo La Plata* **4**, Geol., 339–51(1939).—Analysis of 2 fragments of a meteorite fallen at an unknown date, in the Province of Rioja, gave d. 7.660, 7.860; Si residue 0.034, 0.048; Fe 95.354, 92.220; Ni 4.512, 7.420; Co 0.189, 0.378; graphitic C 0.032, 0.021; S 0.015, 0.012; P 0.216, 0.219; Mn 0.006, 0.007; Sn 0.032, 0.032%; Cr traces; Mo traces; Cu traces. A. H. Krappe

Note on the meteorite of Aguila Blanca. Enrique Herrero Ducloux. *Inst. museo univ. nacl. La Plata, Notas museo La Plata* **4**, Geol. 353–60(1939).—An analysis of a meteorite, fallen in 1921 in the Province of Cordoba, gave d. 3.531, SiO_2 39.215, Al_2O_3 3.214, Fe_2O_3 trace, FeO 10.319, MnO 0.178, TiO_2 trace, Cr_2O_3 0.610, CaO 1.724, MgO 22.611, NiO 1.900, CoO trace, K_2O 0.213, Na_2O 1.386, SO_3 trace, P_2O_5 0.213, S 1.064, Fe 15.576, Ni 1.985, Co 0.034, Mn 0.011 and P 0.035%. A. H. Krappe

German ore deposits and the chemistry of ore deposit formation. K. Keller. *Metallwirtschaft* **18**, 985–90(1939). —A review. Michael Fleischer

Mineralogy of the Esaul polymetallic deposits in the Nagol'nyĭ Kryazh region. P. K. Belik. *Zapiski Vserossiĭskogo Mineral. Obshchestva* **1938**(2nd Ser.), Pt. 67, No. 1, 67–73; *Khim. Referat. Zhur.* **2**, No. 5, 31(1939).—The gang minerals are quartz and ankerite. Most veins contain no ores. Among the ore-contg. deposits are found galena, zinc blende, bournonite, tetrahedrite, boulangerite and jamesonite. The last 2 minerals are described in detail and analyses are given. The deposits are considered to belong to the upper mesothermal zone. W. R. Henn

Magmatic metallogenesis. Cornelio L. Sagui. *Pub. inst. fisiograf. y geol., Univ. nacl. Rosario* **3**, 5–15(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 188–90; cf. Holmes, *C. A.* **20**, 3414.—Radioactive evidence and other evidence in favor of the magmatic origin of Pb and some other ores, as opposed to its origin through segregation from the surrounding rocks, are discussed, and the suggestion is made that under the enormous pressures on a deep-seated magma some of the lighter atoms might unite to form Pb, etc. C. A. Silberrad

Bismuth deposits in the Ural mountains. F. I. Rukavishnikov. *Bull. acad. sci. U. R. S. S., Classe sci. math. nat., Sér. géol.* **1938**, No. 1, 147–51; *Khim. Referat. Zhur.* **1**, No. 11–12, 68(1938).—The Karabutakskiĭ deposits consist of 6 quartz veins 0.15–0.60 m. cutting through granite. The paragenesis of the minerals is muscovite, bismuthite, chalcopyrite, molybdenite, pyrite, beryl, covellite, Bi ocher, Mo ocher, limonite and Cu green. A geochem. diagram of the Karabutakskiĭ vein is given. W. R. H.

Zoned ores of zinc blende and galena. Pierre Evrard. *Ann. soc. géol. Belg., Bull.* **63**, 104–7(1939–40).—Polished surfaces, etched with hot *N* HCl, indicated the brown blende (which surrounded cream-colored blende itself enclosing galena crystals) owed its color and lesser etching to the presence of minute inclusions of galena, often less than 5 μ in size. D. W. Pearce

Rutile in Goyaz (Brazil). O. H. Leonardos. *S. F. P. M. Rio de Janeiro, Bol.* No. **30**(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 186.—The rutile occurs almost pure (averaging 97% TiO_2 and 3% Fe_2O_3) in porphyroblastic masses often weighing several kg., in Algonkian metamorphic schists. So far only alluvial deposits have been worked; the yield was some 400 tons in 1937. C. A. Silberrad

Ilmenite deposits in the region of Egersund and Bjerkreim (Norway). P. Michot. *Ann. soc. géol. Belg., Bull.* **63**, 80–3(1939–40).—The anorthosite-leuconorite can be subdivided by the ilmenite content; the older intrusion has only rare, small grains but the younger is rich in ilmenite. It was concd. in residual liquors after the crystn. of the main mass of the intrusions. D. W. Pearce

The wolframite occurrence at Rothau. J. Frieser. *Z. prakt. Geol.* **47**, 188–92, 205–8(1939).—Veins of ferberite in granite and phyllite are being prospected. An analysis of ore concentrates (WO_3 65%) is given. M. F.

Chromite at Piui (Minas Geraes, Brazil). G. B. Guimarães and J. M. de Oliveira. *Mineração e metallurgia* **3**, No. 14(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 220.—This recently discovered deposit of chromite is characterized by its high content (57%) of Cr_2O_3. C. A. Silberrad

Radium, uranium and polonium in Canada. E. Kohl. *Z. prakt. Geol.* **46**, 188(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 187.—The various deposits, yielding one or more of Ra, U, Ag, Au, Ni and Co in the neighborhood of the Great Bear and Athabasca lakes, are briefly described. C. A. Silberrad

The Yamagata bentonite and its origin. VII. Relation between bentonite and acid-clay. Mune Utida. *J. Japan. Ceram. Assoc.* **47**, 63–7(1939); cf. *C. A.* **33**, 1113⁶.—U. concludes that bentonite and acid-clay or fuller's earth is the same clay substance and they must contain at least montmorillonite and beidellite as 2 common principal minerals. Av. compn. is tabulated. S. Kondo

Ceramic clay in Hawaii. C. K. Wentworth, R. C. Wells and V. T. Allen. *Am. Mineral.* **25**, 1–33(1940).—Ceramic clay occurs in the summit swamps of Molokai, Maui and Kauai and along the crest of the Koolau range on Oahu. Only the Koolau clay has been used and tested in substantial amts. Three complete analyses show marked variation of compn. TiO_2 may reach 15%, probably present as leucoxene and ilmenite. Illite is the chief mineral; kaolinite from plagioclase is present in small amt. The clay has apparently formed by the weathering of basalt. C. H. Hale

The diatomite deposit of Hateg Dobroudja, Rumania. Christache V. Oprea. *Bull. sect. sci. acad. roumaine* **20**, No. 8–10, 49–60(1938)(in French).—From the surface downward is arable soil (0.3 m. thick), altered loess (0.5 m.), fine powdery limestone (0.3 m.), diatomite (2–2.5 m.), red calcareous clay (0.1–0.2 cm.) and limestone. The diatomite, sp. gr. 2.14, when dry has an absorbing power of 97–138 per 100 g. Analysis gave SiO_2 73.29, Al_2O_3 9.12, Fe_2O_3 3.71, CaO 0.53, MgO 0.14, H_2O 11.48, CO_2 + org. 1.73%. Comparison is made with 6 analyses of similar materials (cf. Filipescu, *Inst. geol. Românieĭ, Compt. rend.* **18** (1929–30); Preda, *Ibid.* **20**, 67–78(1931–32)). D. W. Pearce

The coal deposits of northern Hungary and Carpatho-Russia. István Vitális. *Bányász. Kohász. Lapok* **73**, 21–6(1940); cf. *C. A.* **34**, 1152⁹.—A general description. S. S. de Finály

Salt content of the Raselm seas. V. Grimalschi and Vl. Hohor. *Bull. sect. sci. acad. roumaine* **20**, No. 1–3, 17–26(1938)(in German).—The influences of the various canals, etc., upon the NaCl content of the Raselm and Babadag seas were established by monthly detns. of salt content. D. W. Pearce

Annual review of Swedish geological literature for 1938. R. Sandegren. *Geol. Fören. Förh.* **61**, 463–89(1939); cf. *C. A.* **33**, 3304³.—Twenty-five out of the 139 titles are chem. Some are accompanied by short abstracts in English. Wilhelm Segerblom

Isodielectric lines and geologic structure. H. Löwy. *Phil. Mag.* **29**, 32–5(1940); cf. *Ibid.* **27**, 576(1939).—Formulas have been previously given for the dielec. consts. of rocks not satd. by water vapor. Special applications of the formulas are considered here. A formula is derived for the relationship between the dielec. consts. and the infiltration depth of rain. The water content of rocks can be calcd. Data are given for observations carried out in part of the Egyptian Western Desert. Isodielec. lines

are defined. These reveal the hydrologic and hydrographic structure, being lines of max. water content. Applications of the isodielec. lines are illustrated.
S. Tolansky

Propylitization and related types of alteration of the Comstock Lode. Robert Coats. *Econ. Geol.* **35**, 1 16 (1940).—Review of the literature shows that the term propylitization has been used to describe a variety of different types of alteration, which may have been produced in different ways. Re-study of the propylites of the Comstock Lode, the type locality, leads to the suggestion that the term propylite be restricted to rocks which are altered andesites contg. epidote, chlorites, albite and calcite, the ferromagnesians having been altered as well as the plagioclase. In the Comstock Lode, propylitization is the result of hydrothermal metamorphism. M. Fleischer

A case of lateritization in the Belgian Congo. M. Legraye. *Ann. soc. géol. Belg., Bull.* **63**, 76-9(1939-40).— "Dolerites," with ophitic texture, contg. plagioclase, augite and hornblende as essential and biotite, chlorite, sericite and quartz as accessory constituents have become lateritized (see Lacroix, *Publ. bur. études géol. et minières coloniales*, **1934**; Agovnoff, *et al.*, *Ibid.* No. **12**, 1939); they yield a yellow earth, dotted with white and brown patches which have come from decompn. of feldspar, augite and hornblende in place. D. W. Pearce

Granitization near Killarney, Ontario. Terence T. Quirke. *Bull. Geol. Soc. Am.* **51**, 237 54(1940); cf. *C. A.* **24**, 4248; Jones, *C. A.* **25**, 2671.—Q. reiterates, on further study, his previous opinion that the so-called Killarney stony porphyry is an ultra-metamorphosed (migmatized) quartzite. Michael Fleischer

Glaucophanic hornblende in Bohemia. Michael Stark. *Vestnik Královské České Společnosti Nauk* **1936**, 11, 7 pp.(1937); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 263.—This occurs in the cryst. schists of Bohemia and originates from rocks of the calc-alkali and alkali series. Secondary hornblendes of this tract, not essentially glaucophanic, are also described. C. A. Silberrad

Pegmatites and their minerals. Rudolf Mosebach. *Senckenbergiana* **20**, 443-62(1938); *Neues Jahrb. Mineral., Geol.*, Ref. I, **1939**, 548-9.—Complete analyses are given of muscovite, biotite, black tourmaline, barite and garnets (8 from pegmatites, and 2 from other rocks). The pegmatitic garnets are all spessartite contg. up to 40% almandite, some grossularite and occasionally pyrope.
C. A. Silberrad

The rapakivi of Head Harbor Island, Maine. Ruth D. Terzaghi. *Am. Mineral.* **25**, 111 22(1940).—Large rounded K-feldspar phenocrysts are mantled by oligoclase; the rapakivi is a facies of the normal granite of Jonesboro. The origin of this structure appears to have been igneous; alternate pptn. of perthite and oligoclase is perhaps due to change of phase boundary rather than change of magma compn. Analyses of the perthite ovoids and of the oligoclase are given. C. H. Hale

The chemistry of the lamprophyre and mondhaldeit dike rocks of the Kaiserstuhl. J. Soellner. *Zentr. Mineral., Geol.* **1939A**, 300-19, 321-38(1939).—The course of differentiation of the Kaiserstuhl rocks has been assumed to be anomalous. Three new analyses of monchiquite show that it is a typical lamprophyre rock, but 2 new analyses of mondhaldeit rock indicate that it is not a lamprophyre, but is related to monzonite-syenite. The previous analyses were in error, and the course of differentiation was quite normal. Michael Fleischer

The change from greywacke to schist near Blenheim, Marlborough. W. J. Branch and J. A. Bartrum. *New Zealand J. Sci. Tech.* **21B**, 157-61(1939).—Petrographic study shows that the change is abrupt, not gradational, as previously supposed. Michael Fleischer

The weathering of the Nordingrå Gabbro. Harry v. Eckermann. *Geol. Foren. Forh.* **61**, 490-6(1939)(in English); cf. *C. A.* **32**, 6987[7], 6988[6].—Analyses of fresh pegmatitic gabbro and arkose gabbro are given. The pyroxene was most strongly attacked by weathering, the plagioclase next and the orthoclase least; the apatite was unaffected. On the assumption that Al_2O_3 is the least sol. component and const., the arkose analysis recalcd. to the gabbro Al_2O_3 percentage shows a loss in SiO_2 (8.4%), CaO (6.4%) and Na_2O (1.1%) and a gain in Fe_2O_3 (4.9%), K_2O (1.0%) and H_2O (0.8%); also a gain in the ferric-ferrous ratio. A similar comparison is given for the arkose and rapakivi ratio. The causes for the changes are discussed, the different compns. of the feldspars seeming the most likely cause. Wilhelm Segerblom

Geological foundation of the hot springs of Johannisbad. II. The rocks. A. Watznauer. *Firgenwald* **11**, 101-11 (1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 86-9.—A fairly detailed description of these rocks and their mutual relations, with suggestions as to their probable origins. They are classified as rocks of the quartzite series; of the calcareo-red shale series, including dolomitic limestone; calcsilicate rocks and green schists; rocks contg. well-developed albite crystals, the albite constituting up to 90% of the rock; rocks contg. glaucophane or glaucophenitic hornblende; rocks contg. much tourmaline (these are usually connected with the last 2 classes) and dikes of hornblende and mica porphyrites.
C. A Silberrad

Organic content of recent marine sediments. Parker D. Trask. *Recent Marine Sediments: a symposium*, *Am. Assoc. Petroleum Geol.* **1939**, 428-53.—A review of the nature and amt. and source of the org. matter in sediments. 67 references. George Ayers

Mineral analysis of sediments. F. J. Pettijohn. *Recent Marine Sediments: a symposium*, *Am. Assoc. Petroleum Geol.* **1939**, 592-615.—A review and detailed procedure for the detn. of mineral frequency in sediments. 57 references. George Ayers

Base exchange in relation to sediments. W. P. Kelley. *Recent Marine Sediments: a symposium*, *Am. Assoc. Petroleum Geol.* **1939**, 454-65.—Sediments relatively high in clay are especially susceptible to base exchange, with modification of their properties. A discussion of base exchange in relation to crystal structure and to sea water is included. 19 references. George Ayers

Application of x-ray methods to the investigation of recent sediments. Martin Mehmel. *Recent Marine Sediments: a symposium*, *Am. Assoc. Petroleum Geol.* **1939**, 616-30.—After mech. analysis of the sediment, the particles larger than 1 micron are analyzed optically, while those less than 1 micron in radius, if cryst., are detd. by x-ray methods. A detailed procedure is given for identification of calcite, aragonite, quartz, mica, kaolinite, halloysite, montmorillonite, dolomite, feldspar, augite, hornblende, muscovite, biotite, glauconite, diaspore, bauxite, hydrargillite or limonite in sediments by x-ray methods, provided it makes up 5% or more of the sample. 49 references. George Ayers

Aeolian deposits in marine sediments. O. E. Radczewski. *Recent Marine Sediments: a symposium*, *Am. Assoc. Petroleum Geol.* **1939**, 496-502.—Sediments probably due mostly to regular dust falls off the west coast of Africa, in the vicinity of Cape Verde, contain many rounded quartz grains that are coated with red-brown iron oxide. The no. of these desert quartz grains in a sediment gives an indication of the extent to which the deposit is of aeolian origin. 17 references. George Ayers

General procedure in studies of recent sediments. W. H. Twenhofel. *Recent Marine Sediments: a symposium*, *Am. Assoc. Petroleum Geol.* **1939**, 525-31.—Procedures for field studies, sampling and lab. analyses are given in detail. George Ayers

Mechanical analysis [of sediments]. Stina Gripenberg. *Recent Marine Sediments: a symposium*, *Am. Assoc. Petroleum Geol.* **1939**, 532-57.—A review of methods for the detn. of the particle size-distribution relationships of sediments. 64 references. George Ayers

Magnetite content of the sands at the mouth of the Simeto River. Barbara Tanteri. *Ann. chim. applicata* **29**, 474-9(1939).—These sands contain 23¼% magnetite which is similar in compn. to the magnetite in the lava and sands of the nearby Monte Rossi. A. W. Contieri

Recent loess, mode of formation and origin in Upper Normandy and Picardy. Constant P. Nicolesco. *Bull. sect. sci. acad. roumaine* **20**, No. 1-3, 48-58(1938)(in French).—Review and discussion. D. W. Pearce 1

Nature of soil parent materials in Southern Brit. Columbia (Kelley) **15**. Surface diffusion on polycrystals and processes of staining of minerals (Nikiforov) **2**. Comparative x-ray studies of arsenates and selenates (Kokkoros) **2**. Dental enamel and F (Klement) **11F**. Raw material of prehistoric and early Fe (Hundt) **9**.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, OSCAR E. HARDER AND RICHARD RIMBACH

Developments in metallurgical engineering and metallurgical teaching in the last ten years. D. J. Demorest. *Ohio State Univ., Eng. Expt. Sta. News* **12**, No. 1, 11-13 (1940). E. J. C. 3

Single crystals in metallurgy; their production and utilization in the study of deformations. Léon Guillet, Jr. *Rev. gén. sci.* **50**, 424-32(1939).—A review with 12 references. G. G.

Raw material of prehistoric and early iron. Rudolf Hundt. *S.-A. Geraer Ztg.* **1938**, 2 pp.; *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 735.—From the sites of bloomery hearths and places of finding blooms (weighing up to 100 lb.), it is concluded that the first ores smelted were clay ironstone nodules from the Upper Zechstein of E. Thuringia. C. A. Silberrad 4

Whence came tin in the early bronze age? Wilhelm Witter. *Mannus* **28**, 446-56(1936); *Neues Jahrb. Mineral., Geol.*, Ref. II, **1939**, 733 4.—Possible sources and probable dates of earliest working are discussed. C. A. Silberrad 5

Progress in milling practice and equipment. A. W. Fahrenwald. *Mining Congr. J.* **26**, No. 1, 17-22(1940).—A survey of progress in mineral dressing and technology including mech. advances, gravity concn., stratification, thickening, filtration, flotation and the use of the new wetting agents as frothers. Leopold Scheflan

Concentrating Tri-State ores by differential-density cone. Elmer Isern. *Mining Congr. J.* **26**, No. 2, 16-19 (1940).—The ores of the district in Oklahoma, Kansas and Missouri consist principally of galena and sphalerite in a silicate gang of chert or flint. Fine-ground galena in water is used as a concg. medium; it has the same d. and viscosity as has acetylene tetrabromide soln. The differential-density cone process being used by the Eagle-Picher Mining & Smelting Company and by the American Zinc Company of Tennessee is now treating at the rate of approx. 3,500,000 to 4,000,000 tons of Zn ores annually. Leopold Scheflan 6

Domestic sources of deficient minerals. D. F. Hewett. *Mining Congr. J.* **26**, No. 1, 26-9(1940).—This survey deals with the occurrence in the U. S. of Sn, Ni in basic rocks, Mn, chromite, W from disseminated scheelite, Hg, Sb and bauxite. Leopold Scheflan 7

Mining and milling at the Cherokee mine. Phil Burch. *Mining J.* (Phoenix, Ariz.) **23**, No. 18, 2-3(1940).—Au mining in California is described. Because of drainage into a public reservoir the problem of tailing disposal was solved by thickening the pulp and pumping it to a dam while the thickener overflow is utilized as addnl. mill supply. Leopold Scheflan 8

Utilization of lean tungsten ores. O. A. Deminova. *Tsvetnye Metal.* **1939**, No. 7, 48-50.—Large deposits of low-grade W ores (0.1-0.2% W) of Siberia and central Asia have not been exploited commercially chiefly because the technology has not been developed. Expts. showed that concentrates can be obtained from ores contg. as little as 0.1-0.12% WO_3 by a comparatively simple process. Expts. were made on a sheelite-chalcopyrite ore contg. 0.12% WO_3. The gang minerals are mainly feldspars, calcite and sphalerite. A process was developed whereby a table concentrate of Cu-W is obtained first, and then the Cu concentrates are sepd. by flotation from the W concentrates. For table concn. the ore is crushed to less than 1 mm., and for selective flotation to −60 mesh. Cu is floated without difficulty by butyl xanthate and pine tar. For flotation of W concentrates, oleic acid, sodium oleate and water glass are used. It was found that the chief impurity retarding the process of flotation of sheelite is calcite. Calcite, however, can be removed by treatment with 10% HCl. By this method concentrates contg. 32% WO_3 can be obtained with up to 78% extn. B. N. Daniloff 9

Beneficiation of tailings at Zyryanov ore-dressing plant. A. S. Sladkov. *Tsvetnye Metal.* **1939**, No. 7, 66-71.—Old tailing dumps at Zyryanov Works contain approx. Pb 0.85, Zn 3.25, Cu 0.20, Fe 6.20% and some Au and Ag. S. worked out a concn. scheme whereby extn. into the concentrates and intermediate products of approx. Pb 75, Zn 63, Cu 100, Fe 75, Au 90 and Ag 80% is possible. This scheme was recommended for installation. The Zn, pyrite and Au-pyrite concentrates are sufficiently rich in metals to be used in industry. B. N. Daniloff

Treatment of the tailings of amalgamating plants. G. S. Kasatkin. *Zolotaya Prom.* **1938**, No. 11, 28-30; *Khim. Referat. Zhur.* **2**, No. 5, 83(1939).—Tailings of the amalgamating plant were treated by the cyanide process, the Au was adsorbed on wood charcoal and the charcoal treated by flotation. By 24-hr. agitation in NaCN soln., 91.5% of the total Au in the tailings was dissolved with an expenditure of NaCN of 150 g./ton. Max. adsorption of Au was obtained by a 4-hr. contact of the soln. with charcoal. About 13.3 kg. of charcoal was added to the pulp for each ton of tailings used. The extn. of Au was 98%. The soln. must be neutral or slightly acid. The charcoal pulp was floated with a ratio solid:liquid = 1:4 for 25 min. The reaction was either neutral or slightly acid. The Au extn. was 90% of the amt. in the starting materials. Desorption of Au from the charcoal by boiling in NaCN solns. consumes large amts. of cyanide and requires a prolonged boiling. W. R. Henn 10

Oxidation of chalcopyrite under conditions of pulverization and flotation. S. I. Mitrofanov and V. D. Benenson. *Tsvetnye Metal.* **1938**, No. 11, 53-5; *Khim. Referat. Zhur.* **2**, No. 5, 81(1939).—The effects of pH, temp., time of pulverization and aeration and the percentage of the liquid in the pulp on the oxidation of chalcopyrite during pulverization and flotation were investigated. Cu^{++} and Fe^{++} and a no. of S oxides were the sol. products of oxidation. The amt. of S which enters soln. can serve to det. the decompn. of chalcopyrite, and the power to reduce $KMnO_4$ shows the relative amts. of the lower oxides of S. The oxidation of chalcopyrite increases with increase of alky. of the pulp. It is more energetic in a lime medium than in a soda medium. Oxidation increases with temp., time of pulverization, percentage of liquid in the pulp. The floatability of Zn blende on addn. of chalcopyrite increases as a result of activation by Cu^{++} (produced by oxidation of chalcopyrite after the pulverization) and of the adsorption of CN^- by chalcopyrite, which lowers the concn. of cyanide in the soln. and, thus, lowers the degree of depression by the cyanide. W. R. Henn 11

The reactions of iron sulfide with oxides, carbonates,

silicates and phosphates in presence of carbon on heating the mixed powdered material. W. Oelsen and H. Maetz. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* 21, 335–51(1939).—The reactions in the desulfurization of Fe in the blast furnace at high temp. are well known; the reactions at low temp. are little known. A study was made, therefore, of the temp. of the beginning of the reactions. The fundamental reactions FeS + MO → MS + FeO and FeO + C → Fe + CO can take place at a temp. below the m. p. of the reactants. These reactions were more closely investigated for a series of metal oxides by intimately mixing and heating them with FeS and charcoal and detg. the loss in wt. CaO, SrO and BaO react exothermally with FeS at temps. considerably lower than the temps. (900–1050°) of rapid reduction of FeO by charcoal. Therefore, the total reaction is practically finished with these oxides below 1050°. MnO reacts in the range 900–1050° with FeO and C to form MnS; MnO is reduced to Mn at 1320–1450°. MgO gives MgS + Fe + CO strongly only above 1350–1500°. Cr_2O_3 reacts with FeS and charcoal at about the same temps. at which Cr_2O_3 alone is reduced by charcoal, i. e., at 1100–1250°; the reaction is almost complete at 1350–1400°. The reaction of finely divided SiO_2 with FeS and charcoal is so strong in the range 1460–1480° that thick clouds of gaseous SiS are formed and the heating curves show a recalescence point. Reaction of Al_2O_3, FeS and C is very active only beyond 1600°. $CaCO_3$, $SrCO_3$, Na_2CO_3, K_2CO_3 and $CaNa_2(CO_3)_2$ begin to react with FeS and charcoal at lower temps. than do the oxides, and also at considerably lower temps. than the dissocn. temps. of the carbonates in presence of charcoal. The silicates, aluminates and phosphates show in general less reactivity than the oxides and carbonates. Twenty-three references. M. Hartenheim

Experiments in manganese-ore dressing. A. L. Engel and S. M. Shelton. *Mining J.* (Phoenix, Ariz.) 23, No. 19, 2–3(1940).—Extensive tests in concg. Mn ores have led to the conclusion that the texture of the ore, as regards the assocn. of Mn minerals with gang, is far more important from an ore-dressing standpoint than the grade of ore as represented by the Mn assay. Leopold Scheflan

Introduction of solid fuel into bauxite charge in sintering. K. E. Manoilov and A. A. Benglyants. *Tsvetnye Metal.* 1939, No. 2, 114–18.—Lab. expts. made to investigate effect of solid fuel, such as anthracite, coal and peat, into the charge of bauxite-lime-soda for sintering. Solid fuels were added in such quantities as to generate 10 to 50% of the heat required for sintering by the ordinary process without the addns. It was found that (1) solid fuel does not decrease the quantity of sol. Al_2O_3 in the cakes, and (2) porosity increases from the usual 5–8 to 22% on material of one smelter and to 55% on that of another. Most complete combustion was obtained with anthracite. Introduction of solid fuel on a com. scale is to be tried. It is claimed that by this method liquid fuel can be partly substituted by a solid, and that longer service of furnace refractories at the hot end is expected. B. N. Daniloff

Working up oxidized nickel ores of low nickel content. M. H. Caron. *De Ing.* 54, No. 2, 15–27; *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 750.—After a brief account of methods of dealing with such ores, C. describes his own, which depends on a selective reduction of the free or combined NiO in the ore with selective extn. of the reduced Ni, whereby the liquor, an ammoniacal NH_4 carbonate soln., is completely recovered by distn.; this leaves only a very small amt. of NH_3 in the residue after washing. From the $NiCO_3$ a very pure metal is obtained. C. A. Silberrad

The smelting of titanium-containing sandy iron ore. Huzio Kakiuti. *Tetsu-to-Hagane* 23, 947–53(1937); *Chem. Zentr.* 1938, I, 4372.—By the usual procedure it is not possible to sep. the TiO_2 from sandy Japanese Fe ore because the grains are too small. The Fe sponge obtained from this ore by reduction at 1100° still contains so much TiO_2 as greatly to impair the quality of the Fe. A process is developed which eliminates this disadvantage. From ore contg. about 58% Fe and 13% Ti it gives an Fe yield of about 82% bloom with an av. total content of Fe 94 and O 2.5–3, S <0.02, SiO_2 <1.00, CaO <0.25 and TiO_2 <1.80%. M. G. Moore

The treatment of poor Kopotin schists. B. N. Lebedev. *Zolotaya Prom.* 1938, No. 11, 27–8; *Khim. Referat. Zhur.* 2, No. 5, 83(1939).—For recovery of Au from these schists, amalgamation (when the ore was ground to 40–60 mesh) gave a 60–5% extn. The cyanide process gave a fairly complete extn., but the method is economically unsound. Flotation is the best method: the extn. of Au amounted to 87–92% with a 6–15% yield of the concentrate. W. R. Henn

The choice of the most rational composition of blast-furnace slag for the Magnitogorsk blast furnaces. G. S. Korobova. *Sovet. Met.* 9, No. 9, 23–7(1937); *Chem. Zentr.* 1938, II, 3446.—A comparison of data reported in the literature with K.'s expts. leads to the conclusion that slag contg. 35–7% SiO_2 is most satisfactory. Under such conditions crude Fe was obtained having a Si content of 1% together with a low S content and a m. p. between 1265 and 1400°. The slag had a proportionately high viscosity, which, however, did not exceed the permissible limits, and stabilized the fusion temp. quite well, the fluctuation being ± 50° for a SiO_2 variation of ± 2%. M. G. Moore

Obtaining slag wool from blast-furnace slags. A. Z. Azovskiĭ. *Stroitel. Prom.* 17, No. 7, 58–60(1939).—Semiplant investigations demonstrated that it is possible to obtain standard-quality slag wool from liquid slag directly from the blast furnace by means of a steam blast at 9–10 atm. E. E. Stefanowsky

Effect of the surface layer of slag on the losses of copper and of precious metals in the residual slag of reverberatory furnaces. M. E. Balykin. *Tsvetnye Metal.* 13, No. 10, 71–4(1938); *Chimie & industrie* 42, 285.—The enrichment of residual slag in Cu is due to a large extent to the presence in the slag of unfused cupriferous charge which is evacuated at the same time as the slag owing to the high level of the latter and the insufficiently high temp. of the furnace. As the level of the slag rises, the rate of advancement of the surface layer during removal increases and entrains particles of the charge. A. Papineau-Couture

The influence of silica, titania and alumina on the viscosity of acid synthetic slags and the calculation of the viscosity of acid and basic blast-furnace slags from their chemical composition. K. Endell and G. Brinkmann. *Stahl u. Eisen* 59, 1319–21(1939).—Original research supplementing previous work. Acid synthetic slags become increasingly viscous as the SiO_2 content is increased; at 50.4% SiO_2 the value for the viscosity becomes greater than the max. attainable viscosity of blast-furnace slag of η = 75 CGS. TiO_2 lowers the viscosity at least up to 17.3% TiO_2, so that in smelting Ti-contg. ores no difficulties should be met because of slag viscosity. Increasing Al_2O_3 raises the viscosity, and also the temp. at which crystals sep. out, the results here being in agreement with those obtained at Corby. A hyperbolic curve is shown giving the relation between the viscosity a 1400° and the chem. compn. S. Epstein

Composition of the stock in the slag-forming region of blast furnace No. 1 at Magnitogorsk. M. M. Leĭbovich. *Trans. Leningrad Ind. Inst.* 1938, No. 6, Sect. Met. 89–110(in English, 110–11).—The primary slags in the top part of the bosh and in the lower inwall contain all the component parts contained in the final slag and suspended particles of the fuel. Mostly the slags formed are of the low-iron type. By increasing the blast the FeO and MnO in the initial slags decrease but an increase of magnesia therein should counteract this decrease and make the slag sufficiently fluid. By adding $MgCO_3$ to the charge the content in the initial slags is increased to the same extent as in the final slags. The initial slags under investigation had less alumina than the final slags, a higher ratio of SiO_2/Al_2O_3, and a higher basicity. The MnO in the primary slag was about twice that in the final slag, the S content was 3/4 that of the final S content in the slag. Tests showed the presence of all types of metal from sponge iron to eutectic white iron at the same furnace

level. Iron of the same compn. but lower Si content than the final hot metal is found in the bosh. About ⅔ of the metal samples contained more than 1.7% C and the rest were steel and pure iron. In the lower inwall steel was mostly found but iron was also present. B. Z. Kamich

Methods of measuring high temperatures in blast furnaces. N. M. Yakubtsiner and M. M. Vorovich. *Trans. Leningrad Ind. Inst.* **1938**, No. 6, Sect. Met. 3–21(in English, 21–2).—The e. m. f. of W-graphite thermocouple was detd. experimentally for the interval 1600–1900° and graduated in a W furnace with an optical pyrometer. The graduation was checked by temp. measurements of liquid metal and slag with Pt-Rh and W-graphite thermocouples. The readings are not affected by reducing or oxidizing atm. More accurate results are obtained with thin graphite rods but these are not mechanically strong and for measurements in the tuyère region thick rods are preferable. With this couple it is possible to obtain an accurate temp. curve along the entire furnace radius including the "focus of combustion." A method is described for measuring the temp. of the iron and slag during tapping. These readings are more accurate than those obtained with an optical pyrometer. It is shown that there is a relation between the temp. of the metal and the Si and S content. B. Z. Kamich

The technological-economic basis for the use of oxygen-enriched air in blast furnaces. M. A. Shapovalov. *Teoriya i Praktika Metallurgii* **1938**, No. 7–8, 3–6; *Khim. Referat. Zhur.* 2, No. 5, 76(1939).—In the production of ferrosilicon, blowing with O yields high-alumina, low-silica slags which are suitable for the production of Al_2O_3 and of cements of high quality. The blast-furnace gas produced can be used for the manuf. of NH_3. A layout is described. In order to increase the Al_2O_3 content in the slag bauxite is added to the mixt. This process for each ton of ferrosilicon and slag used with a blast contg. 60% of O produces a blast-furnace gas contg. CO 73.4, CO_2 5.45 and N 20.70%. A similar process with a blast contg. 45% of O produces CO 62.3, CO_2 5.7 and N 31.6%. It is recommended to use a 40% O blast for ordinary grades of cast iron and ferromanganese. The O blast in smelting ordinary grades of cast iron increases considerably the productivity of the furnace without increasing the blast, and it lowers the required height of the blast furnace. W. R. Henn

Investigation of the reducing process in blast furnace No. 1 at the Magnitogorsk steel plant. I. Z. Kozlovich. *Trans. Leningrad Ind. Inst.* **1938**, No. 6, Sect. Met. 112–44 (in English, 144–6).—An investigation of the reducing process in blast furnace No. 1 of the Magnitogorsk steel plant indicates that the reductions are nearly completed in the lower part of the inwall and in the bosh. Therefore, the boshes and the hearth could carry an addnl. load and thus reduce the stay of the charge in the furnace from 8 to 5 hrs. The use of agglomerate instead of raw ore would also improve operations. B. Z. Kamich

Regulating the operation of a McKee charge distributor in a large blast furnace. I. A. Gorelik. *Trans. Leningrad Ind. Inst.* **1938**, No. 6, Sect. Met. 23–47(in English, 47–8).—Expts. are described on the regulation of a McKee charge distributor in a large blast furnace of the Magnitogorsk plant. The expts. have shown that by modifying the operation of the McKee top to charge more ore over the iron and cinder notches results in uniform gas compn. and uniform gas distribution through the furnace cross-section. The amt. of extra ore to be charged should be detd. experimentally on the basis of gas analyses. B. Z. K.

Movement of the charge in a large blast furnace. D. V. Efremov. *Trans. Leningrad Ind. Inst.* **1938**, No. 6, Sect. Met. 49–87(in English, 87–8).—Exptl. data are given on the factors influencing the speed of the downward movement of the charge material in various points of No. 3 blast furnace at Magnitogorsk. B. Z. Kamich

Analysis of the operation of blast furnaces in iron-bauxite smelting. N. N. Kruglov. *Ural. Met.* **1937**, No. 8, 3–11; *Chem. Zentr.* **1938**, II, 3446–7.—Calcn. of the blast-furnace mixt. and heat balance resulted in a 44–72% increase in the crude iron and slag yields and a reduction in the fuel required for the smelting of Fe ores contg. 55.21% Fe, 1.6% MnO, 0.78% MgO, 1.67% CaO, 4.28% Al_2O_3 + TiO_2 and 6.67% SiO_2 with roasted bauxite (2.38% SiO_2, 64.19% Al_2O_3 + TiO_2, 0.68% CaO, 0.44% MgO, 0.25% MnO and 22% Fe). The addn. of burnt lime still further reduced the fuel consumption and increased the furnace output by 22%. The slag obtained could be used in the Al industry. M. G. Moore

The capacity of the VKhZ furnace and methods for its rationalization. N. L. Arkin. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 9, 30–1(1939).—Mech. details of this Russian pyrite furnace are discussed. H. M. Leicester

Absorption and desorption of hydrogen in the manufacture of steel. Sven von Hofsten, Bo Kalling, Folke Johansson and Oof Knös. *Jernkontorets Ann.* **123**, 485–526(1939).—A series of measurements were carried out in full-scale furnaces on gas compn. and the H content of the molten metal during the steel-making process. An inverted graphite crucible fitted to a water-cooled delivery tube was used for drawing off gas samples about 50 mm. below the surface. The graphite crucible remained intact for 0.5–3 hrs. depending on the condition of the slag and the C content of the steel. Samples of the molten metal were analyzed for H by vacuum melting, and for C. The H content of the gas dropped as the C was burned out. This was attributed to the diffusion of dissolved H into bubbles of CO formed during the decarbonization process. On this assumption it was possible to derive an equation, $1/\sqrt{H} = 32\,(C_1 - C) + 1$, where H = partial pressure of H in atms. and $C_1 - C$ = decrease in C content, which approx. reproduced the relation between dehydrogenation and decarbonization. If the furnace gas contains H or any of its compds., the dehydrogenation is incomplete and reaches an equil. value. A reduction of 0.3% in the C seems to be sufficient to reach equil. even with high H content. The absorption of H is promoted by a high partial pressure in the gas and partly hindered by a protective surface slag, but the rate of decarbonization seems to have no influence. Appreciable quantities of H may be absorbed through the use of partly slaked lime, moist ore or leaking doors. There was also some indication that too much tar in the chilled tappings might increase the H. In the comparison of various furnaces the elec. furnace melts showed lower H because of the absence of H in the gases. The acid slags seemed more resistant to absorption than the basic open-hearth slags, and the end gas compns. were 1 and 2% H, resp. In Bessemer and Thomas processes the H content reaches an equil. value dependent on the moisture content of the air used for blowing. H. C. Duus

New methods for controlling the quality of steel during fusion. V. M. Zamoruev. *Metallurg* **13**, No. 6, 51–3 (1938); *Chimie & industrie* **42**, 54.—Control of the quality of steel in the course of fusion is based on the detn. of the degree of deoxidation and of degassing of the bath. In practice, FeO and gas are detd. This may be done either by Herti's method or by a less accurate but more rapid method consisting in deoxidizing the sample with progressively increasing amts. of Al until the metal becomes still; the quantity of Al required corresponds to the O content of the bath. A. Papineau-Couture

Specific properties of molten steel baths. S. M. Baranov. *Metallurg* **13**, No. 6, 56–66(1938); *Chimie & industrie* **42**, 54.—The deoxidizing process applied to the molten steel is the main factor governing the specific properties of the metal. It is necessary to take this into account in the examn. of steels and in studying the relations between chem. compn. and heat-treatment. A. Papineau-Couture

Production and annealing of ingot steel. Emanuel Starck. *Schlägel u. Eisen* **36**, 127–36, 153–7(1938); *Chem. Zentr.* **1938**, II, 3448.—A general review. An explanation is given of the Fe-C diagrams, the types of structures, processes occurring during recrystn. and other factors, a knowledge of which is necessary for proper annealing. M. G. Moore

Smelting of chrome-copper steel for the Soviet Palace and the Moscow Bridge. T. M. Klimov. *Teoriya Prakt.*

Met. 9, No. 8, 61–4(1937); *Chem. Zentr.* 1938, II, 3451.—Directions are given for the smelting, deoxidation and casting of the steel whose compn. is C 0.12–0.2, Mn 0.7–1.1, Si 0.25–0.4, Cr 0.4–0.6 and Cu 0.3–0.7%. M. G. Moore

The influence of temperature and acidity on the form and content of copper in slags. M. E. Balykin. *Tsvetnye Metal.* 1939, No. 4–5, 129–31.—The influence of temp. on the form and content of Cu in slags in reverberatory furnace smelting was investigated. Slags and Au-bearing copper quartz ore were charged into crucibles, melted and held at temps. from 1170 to 1503°. (The compns. of slag and ore are not given.) It was found that the soly. of SiO_2 varies from 36.5% at 1210° to 61.2% at 1503°. At temps. up to 1200° lumps of ore remain unmelted. At higher temps. the quantity of undissolved free SiO_2 in slag decreases and the soly. of Au-bearing ore increases. By settling 30 min., which time was considered sufficient, the total Cu content in slag decreased from 0.39 to 0.23%, and the sulfide Cu from 86.6 to 30.3% of the total as the temp. was raised from 1170 to 1503°. At the same time the Cu in the form of oxide (Cu_2O), silicate and ferrite increased from 25.6% of total Cu at 1170° to 93.3% at 1480°. This increase is due to the formation of Cu_2O as the result of reaction between Cu_2S with Fe_2O_3. The increase of Cu in slag in the form of oxide, silicate and ferrite is counteracted by the decrease in sulfide Cu; the net result of increased temp. is the lower loss of Cu in the slag, and therefore increased recovery of the metal. B. N. Daniloff

Water-jacket fusion of slags and the objectivity of experimental data. V. S. Sokolov. *Tsvetnye Metal.* 1939, No. 4–5, 117–25.—S. discusses the problem of treatment of slags at the Molotov Copper Smelters which has not yet been solved satisfactorily. Largely polemical with reference to I. M. Dubrovin's data (*Tsvetnye Metal* No. 11 (1938)). B. N. Daniloff

Accident prevention in the foundry. H. Mabson. *Can. Metals Met. Inds.* 3, 42–3, 56(1940).—Some of the major problems in accident prevention are briefly discussed. Emphasis is given to the minimizing of the amt. of fine dust suspended in the foundry atm. The following substitutions will help in this direction: metallic abrasive to replace SiO_2 sand for blasting purposes, artificial grinding wheels in place of sandstones, and low-SiO_2 content parting compds. in place of SiO_2 flour. General ventilation may often prove the most economical method of fine-dust removal. The judicial use of water or oil on foundry floors and gangways will go a long way toward reducing the dust hazard incidental to foundry operations. W. H. Boynton

Plastic flow in metals. H. W. Swift. *Metal Ind.* (London) 56, 127–30, 149–52, 173–5(1940).—Review. E. H.

Glycerol in metal processing. Georgia Leffingwell and Milton A. Lesser. *Metal Ind.* (N. Y.) 38, 79–81, 83 (1940).—A correlated abstract on the uses of glycerol in plating solns., electrochem. processes, soldering and hot galvanizing fluxes, quenching solns., polishes and rust removers. 32 references. C. B. Jenni

Austempering and hardenability. J. M. Robertson. *Iron & Coal Trades Rev* 140, 94–7(1940).—The process of austempering, its limitations, advantages and practical significance are described in the light of the present state of knowledge of the subject. I. Hartmann

Structural mechanics of metals at elevated temperatures. Georges A. Homès. *Rev. mét.* 36, 373–87(1939).—An extensive x-ray and metallographic study of the changes taking place in metals at elevated temps. indicated that it occurs spontaneously at all temps. at which the metal is used. The changes occur at grain boundaries among crystals (such as coalescence) and in the dimensions of the crystals, tending to restore the original structure and effect recrystn. Introduction of stabilizing elements under rigidly controlled conditions may effect a pronounced stabilization, but their use is quite difficult. Quenched and annealed steels behave differently in this respect even when heated below the temps. used in their heat treatment. Constituents of drawn metals, such as troostite, etc., respond to heating differently and in a selective manner so as to produce an occasional rapid drop in impact strength. Special elements sometimes increase, sometimes decrease these structural changes. Their effect can be detd. by combined x-ray and metallographic study. J. D. Gat

The heat conductivity of metals and its influence on heat exchange. R. v. Linde. *Metallwirtschaft* 18, 1053–5 (1939).—Although the heat cond. of Cu is very high compared with Al and other light metals, the cond. of alloys of the latter metals is higher than for Cu alloys. Cu with traces of As has only one-third the cond. of pure Cu; brass approx. one-quarter; bronze with 8% Zn, less than one-sixth; constantan (30% Ni) approx. one-seventeenth that of Cu. On the other hand, most important Al alloys have approx. 70% the cond. of pure Al, and Fe alloys are similar in this respect. The heat-transfer characteristics of ribbed or laminated and of smooth-surfaced vessels is exam'd. In the former about one-half the temp. drop is due to restriction on the air flow at the narrowed sections. Poorly conducting metals definitely reduce the heat transfer, but by changing the design to facilitate smooth fluid flow, the effect of poor cond. can be minimized, especially if the heat transfer is not too great. In vessels with smooth walls the cond. of the wall is of minor importance, compared with other influencing factors, as the properties of the boundary layers of the fluids on both sides, dust or oil deposits on the walls, fluid speed, etc. I. Hartmann

Some factors affecting carburization. T. A. Friselman. *Heat Treating Forging* 26, 65–7(1940).—Tests were made to det. the C concn. of 4 steels (S. A. E. 2315, Cr-Ni-V, Cr-V, S. A. E. 1015) carburized simultaneously in the same pot. Total time of carburizing was 15 hrs. and the temp. 939°. The tests showed that the Cr-V steel carburized fastest and S. A. E. 2315 steel slowest. In another test made in a different furnace S. A. E. 1015, S. A. E. 2315 and S. A. E. 3115 steels were used. The time of carburizing was somewhat shorter; the results showed that S. A. E. 3115 steel carburized fastest. The effect of screenings on carburization was investigated and it was found that as far as C concn. is concerned, coarser screenings ($^1/_{16}$ to $^1/_8$-in. in diam.) can be used as effectively as finer dust. Too many fines in the compd. have an adverse influence on the case depth. The effect of Na carbonate (in carburizing pots) on the C concn. of steel was detd. Compds. contg. 2 to 3% Na carbonate have a slight tendency to cause decarburization; lower Na carbonate concn. has little effect on the steel. I. H.

New ways of obtaining and of employing thallium. E. Drescher. *Schlagel u. Eisen* 36, 181–5(1938); *Neues Jahrb. Mineral., Geol.*, Ref. II, 1939, 188.—The methods of production of Tl from lead-chamber slimes, in the purification of Cd, etc. are briefly described. Addn. of Tl improves many alloys, especially those of Pb. An alloy of Pb and Tl contg. 20–65% Tl is very resistant to corrosion, and the Ag-Tl alloy with 10–22% Tl does not blacken on exposure as pure Ag does. Tl is also used as a catalyst. C. A. Silberrad

A metallographic study of internal oxidation in the α-solid solutions of copper. Frederick N. Rhines. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. 1162, 41 pp.(1940).—A group of 40 binary Cu α-solid-soln. alloys was subjected to oxidation at elevated temps. both in the air and in a closed container packed with a mixt. of Cu metal powder and Cu_2O. Internal oxidation was found in the binary combinations contg. Al, Sb, As, Ba, Be, B, Cd, Ca, Ce, Cr, Co, Cb, Ga, Ge, In, Fe, Pb, Li, Mg, Mn, Ni, P, Se, Si, Na, Sr, Ta, Sn, Ti, W, V, Zn and Zr. External oxidation alone was found in alloys with Ag, Pt and Pd. The behavior of alloys contg. Bi, S, Te and Tl was uncertain. The particle size of the pptd. oxides depends on the chem. nature of the alloying element, the concn. of the alloy and the temp. of oxidation. Very stable oxides tend to form fine ppts. while the less stable ones form coarse particles. High temps. of oxidation and high concns. of the alloying element both favor a large particle size. Extensive agglomeration is rarely found. Occasionally Widmanstätten

figures occur. The distribution of the ppt. varies from system to system and with the temp. of oxidation. In some alloys the particle count increases inward and in others the opposite occurs. A more or less uniform distribution of the oxides, which seems to be characteristic of high-temp. oxidation, gradually changes to pptn., predominantly at grain boundaries, as the temp. of oxidation is lowered. The rate of growth of the subscale decreases with time, with an increasing concn. of the alloy, with lower temps. and with lower O pressure; the time to form a given thickness of subscale is almost directly proportional to the concn. of the alloy; the log of the thickness squared is a linear function of the reciprocal of the abs. temp. Ternary alloys contg. Cu with Sn or Zn and Al, Be or Si all exhibited double zones of internal oxidation, the outer band contg. the oxides of both metals and the inner band the oxide of only one metal. The relative widths of the bands can be varied by changing the alloy compn. and the pptn. of one of the oxides may be suppressed by sufficiently lowering the O pressure. Under certain conditions liquation may accompany internal oxidation. An extensive discussion of the application of phase diagrams to the rationalization of oxidation behavior is included. C. L. Mantell

Effect of cold work on hardness and recrystallizing behavior of pure platinum. E. M. Wise and R. F. Vines. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. **1167**, 8 pp.(1940).—The Pt used in the expts. had a probable Pt content of 99.99+%, and had the following mech. properties in the completely softened condition: Vickers hardness no. 39.4, ultimate tensile strength 19,340 lb. per sq. in., proportional limit very low, elongation 37.5% in 2 in. The effect of cold-rolling is such that the hardness increases rapidly up to 10–15% reduction and more slowly up to about 75% reduction, beyond which it increases more rapidly. The recrystn. temps. for a 15-min. anneal, after cold-rolling 19, 39.5, 50.8, 66, 80.5 and 89.5% reduction in thickness, are approx. 765°, 700°, 635°, 600°, 545° and 425°, resp. The recrystd. grain size of this Pt is a function of the percentage of cold reduction, being larger the lower the percentage of cold-work. Little or no grain growth resulted from subjecting recrystd. samples to higher temps. or annealing for longer times. C. L. Mantell

Research in relation to steel metallurgy. W. H. Hatfield. *Iron & Coal Trades Rev.* **139**, 723-5(1939); cf. *C. A.* **33**, 6205[8].—A plea is made for the continuation of research during the war, and developments during the past twenty years are reviewed briefly. I. Hartmann

Progress in steel metallurgy during the last ten years. W. H. Hatfield. *Heat Treating Forging* **26**, 78–80(1940). —See *C. A.* **34**, 1600[6].—A review. I. Hartmann

Albert Sauveur questionnaire and American work dealing with the constitution of steel. N. T. Belaiew. *Rev. mét.* **36**, 313–15(1939).—The advantages and disadvantages of changing metallographic terminology, particularly abolition of troostite and sorbite and introduction of bainite, are discussed. An apparent solution lies in an international meeting settling the point. J. D. Gat

Problems in the manufacture and use of steel products in the U. S. James E. Lose. *Blast Furnace Steel Plant* **27**, 577-81, 586, 680–5, 705–6(1939).—Problems in *tin plate* are: increased uniformity in gage, wt. and flatness; continued improvement of the mech. properties; and improvement both of the base metal and of the Sn coating for continued improvement in corrosion resistance. Uniformity and maintenance involves extreme precaution as to hot-rolling conditions and finishing temps. in the manuf. of strip. Surface must be free from mech. defects and rolled-in scale. Ductility and phys. properties of sheets have changed owing to the introduction of cold-reduced material. Consumption has been increased by applications in automotive fields, furniture, refrigeration, washing machines and railway passenger cars. Improvements have resulted from better grain structure, improvement in steel quality through improved melting practices, and through an understanding of surface texture. Coating-adherence requirements are severe for galvanizing sheets. 1 In *enameling sheets* flatness of stock, drawing quality and surface texture are essential. Machinability and close tolerance are the major problems in the *cold-drawn trade.* Uniformity of chem. analysis, straightness, flatness, are problems in *structural steels.* Freedom from surface imperfections, reduction of crown and overweight, flatness, and elimination of pipe and lamination are problems in *plate manuf.* Chem. compn. of rail is controlled so that each size of rail shall have a hardness appropriate to its size. 2 Interior quality as well as wear resistance of *rails* are now being investigated. Slow cooling of rails minimizes the presence of shatter cracks. The Brunorizing treatment minimizes shatter cracks and improves toughness. "End batter" of rails is being combated by heat treatment and by the use of rails welded into very long lengths. Problems in *railroad wheels* include internal soundness, surface quality and the liability toward internal fissures analogous to shatter cracks in rails. 3 The problem of close tolerance arises in wheels for streamliners as the wheels must approach a dynamic balanced condition. Because of increased braking pressures owing to high operating speeds, the surface of the wheel tread is often heated above its hardening temp. and on cooling develops thin but hard and brittle case on the wheel. Another wheel problem is "shelling" or spalling of the tread surface under heavy loads. Special milling practices and precise heat treatments are necessary in order to meet cleanliness and grain 4 structure requirements for *railroad axles.* Magnaflux testing is useful for inspection of axles for incipient cracks after having been in service. *Wire and wire products* are required to meet closer size tolerances which requires more frequent replacement and reconditioning of wire dies. Surface smoothness and decarburization have definite influence upon the life of springs. *Springs* of unusual combination of strength and hardness are now produced 5 by austempering. Seamless-tubing manuf. and elec. welding processes have introduced many problems in *pipe manuf.* C. B. Jenni

Phenolic plastic applications in the steel industry. H. F. Horne. *Iron Steel Engr.* **16**, No. 9, 66–9(1939).—Laminated materials have low moisture absorption and are light. Certain grades can be used in non-oxidizing acids up to 10% concn. at elevated temps. They will not 6 cut, hammer out, or gall when properly applied for thermal washers, guides or bearings. Oil or grease have no effect on these materials. They are stronger, less porous, harder, and machine better than wood and they do not soften under the effect of water. Applications discussed include: pickling-tank hold-down rolls, up-coiler roll covering, back tension roll and coil spreader, guide boxes and bearings. C. B. Jenni

Progress of lubrication in the steel industry. C. C. Peeu. *Iron Steel Engr.* **17**, No. 1, 45–51(1940).—Progress 7 and development of lubrication engineering in the steel plant. Steps taken to eliminate lost time, excessive repairs, and high power losses included enclosing of moving parts of equipment, improvement in the methods of applying lubricants, and improvement in the lubricants. The design of plant equipment has undergone a refinement resulting in greater ease of effective lubrication. Results 8 have shown increased efficiency and economy resulting from longer life and lower repairs of plant equipment. A list of lubricants is given showing specific applications and types and characteristics of the lubricant for each application. C. B. Jenni

Types of lubricants essential to steel mills. W. H. Mandy. *Iron Steel Engr.* **16**, No. 8, 20–9(1939).—Recommendations for proper lubricants are influenced by such factors as: variations in climatic conditions, proximity to 9 source of cooling water, proximity to industries having contaminating effect on the atm., type and age of equipment, plans for future replacement of machinery, possibility of lubricant contamination, use of salt as scale remover, methods employed in cleaning equipment, heat conditions, and time allowed for lubrication and repairs. In addn. to a few specialty lubricants, the following types of oils and greases are usually found in most steel mills: black oils, journal oils, red engine oils, pale oils, turbine

oils, steam cylinder oils, cup greases, low m. p. pressure-gun greases, high m. p. pressure-gun greases, extreme-pressure grease, extreme-pressure gear lubricants, heavy gear compounds, hard tallow or cold neck greases, hot neck grease. Application of each of these types is discussed. C. B. Jenni

The effect of hydrogen in steels of different composition. W. Eilender, Yü Chih Chiu and F. Willems. *Arch. Eisenhüttenw.* **13**, 309–16(1940); cf. *C. A.* **33**, 5338⁴.— Plain and alloy steels were melted with different methods of deoxidation, the H content was artificially increased, and structure, H content and H escape were detd. The H escape became more difficult in unalloyed steels with increasing C content, and also in low-C steels by addn. of alloying elements, except in Cb steels, in which the velocity of the escape of gas increased with increasing Cb content. Austentic and ferritic steels did not give off gas when stored. From steels with ferritic-pearlitic and martensitic structure gas escaped with the exception of Ti steels. The failure of H to escape in ferritic and austenitic steels is ascribed to the missing A_3 and A_1 transformation, resp., and the reforming of the lattice connected with the transformation; the escape of H in oversatd. steels is very likely connected with the phase transformation. Under certain conditions, Cb can be used as dehydrogenation agent. As most of the alloys used as addns. contained much H it is assumed that they can be a source of H if added only after deoxidizing. Twenty-one references. M. Hartenheim

Improved process for integrally bonding steels of different compositions. Hiland G. Batcheller. *Heat Treating Forging* **26**, 68–71(1940).—The process described is named "Pluramelt," indicating plural or simultaneous melting of the steels to be bonded. A special elec.-arc melting furnace was so designed that both steels to be bonded are melted simultaneously and the final product can be intermelted with any other part and allowed to solidify as an inseparable portion of the unit mass. Exptl. work so far has been limited to Pluramelts of stainless alloys on soft or medium steel, and tool steel types on soft steel bases, but equal success is anticipated with any other alloy that can be melted in an arc furnace. Pluramelt products are available in some com. forms. I. H.

Mechanical properties of alloy steels at low temperatures. A. Krisch and G. Haupt. *Arch. Eisenhüttenw.* **13**, 299–308(1940).—A very exhaustive investigation was made with 62 materials of which notch-impact strength, hardness, ultimate strength and elastic limit, elongation and reduction of area was detd. at +20°, 0, −100, −183 and −253°C. Some Ni, Cr-Ni and Cr-Mn steels, especially those with austentic structure, and Ni, Cu and Pb show a considerable plastic deformability in the notch-impact tests even for temps. down to −183°C. Low-alloy martensitic steels show without exception a reduction of the notch-impact strength down to −183°, whereby alloys with Ni addn. have the highest values of notch-toughness. Some Cr-Mo steels, with or without low Ni content, had even at −183° a notch-impact strength of 5 kg.-m./sq. cm. A hardened steel has, in general, lower notch-impact strength at low temp. Soft Fe becomes brittle at low temp., while the notch-impact strengths of Cu and Pb increase with decreasing temp. Pb and soft Fe show greatest change of hardness on cooling. Cr-Mo, Cr-Ni-V and Cr-Ni-Mo steels showed an increase of the ratio tensile strength to hardness at −183°. The tests are given in full with tables and curves. Thirteen references. M. Hartenheim

Properties, heat-treatment and finishing of stainless steels. E. F. Ingersoll. *Metal Ind.* (N. Y.) **37**, 503–6 (1939).—A review of the compn. of stainless steels with a discussion of the effects of alloying elements. Heat treatment, pickling, passivation and working qualities of stainless steels as well as spinning, shearing, punching, welding, soldering and finishing of stainless steels are considered. A list of finishes of com. sheet is given. C. B. Jenni

Tensile elastic properties of 18:8 chromium-nickel steel as affected by plastic deformation. D. J. McAdam, Jr., and R. W. Mebs. *Natl. Advisory Comm. Aeronaut., Rept.* No. 670, 42 pp.(1939).—The relations between stress and strain and between stress and permanent set for 18:8 alloy as affected by prior plastic deformation are discussed. Hysteresis and creep and their effects on the stress-strain and stress-set curves are also considered, as well as the influence of duration of the rest interval after cold-work and the influence of plastic deformation on proof stresses, on the modulus of elasticity at zero stress and on the curvature of the stress-strain line. Curves of variation of proof stress with prior plastic deformation often have many oscillations between high and low values. Causes of the most abrupt of these oscillations are: variation in the duration of the rest interval and variation in the distribution of the exptl. points throughout the range of extension. These oscillations probably are due in part to variations of internal stress. Variations in the rest interval generally have opposite effects on the slopes of the stress-set and the stress-strain curves. Slight pre-stretching, to the extent of a small fraction of 1%, generally causes considerable improvement in elastic strength. C. B. Jenni

Nickel alloy steels. Characteristics and properties required for tractor parts. H. L. Geiger. *Product Eng.* **11**, 67–70(1940).—A table indicates the particular steels which have the properties required by a given part of crawler or wheel type tractor. Torsion and tension data are given with chem. analysis and phys. properties of some tractor gear steels. A case of eutectoid compn. or slightly higher at the surface is preferred for rolling contact or extremely high unit loads. A case depth of 0.045–0.055 in. is necessary. Ann Nicholson Hird

Structures of very slowly cooled nickel steels. A. Portevin. *Rev. mét.* **36**, 316–21(1939).—To show that phenomena leading to new developments were observed actually long ago, P. presents as a historic curiosity a set of photomicrographs made by him before 1911 which clearly demonstrate the structure presently known as *bainite*. J. D. Gat

Effect of vanadium on grain-boundary precipitation of austenitic chromium-nickel steels. G. Riedrich and G. Hoch. *Stahl u. Eisen* **60**, 30–1(1940).—Addns. of from 0.76 to 3.01% V were made to steels with 18% Cr and with from 9 to 14% Ni. The steels were air-cooled from 1050° and then reheated for 1 hr. at from 500 to 700°. The most damaging grain-boundary pptn. occurred at about 600° and this even in the steels with the highest V content. It was concluded that V does not form a stabilizing carbide even when 25 times as much V as C is present. The slight benefit noted because of the presence of V in diminishing grain boundary carbide pptn. was attributed to the influence of V in increasing the amt. of ferrite. S. E.

The importance of thermal analysis for studying the process of crystallization of commercial alloys. W. Patterson. *Giesserei* **26**, 461–6(1939); cf. *C. A.* **33**, 9248⁸.—Cooling curves of Al-Si alloys (11–14% Si) were obtained by a modification of Kurnakow's method. The curves show the degree of undercooling, the purity of the alloy, the amt. of segregation and the fineness of the structure. A Le Chatelier thermocouple energizes a mirror galvanometer. The light beam registers the cooling curve on a rotating drum fitted with AgBr paper. Hypereutectic alloys undercooled about 2.5°; and hypoeutectic alloys showed negligible undercooling, for cooling rates in the molten bath of approx. 150°/min. Primary crystals of the higher-melting component (Si) had negligible influence on the start of eutectic crystn. For hypoeutectic alloys the 1st-formed primary crystals of the lower-melting component (Al) probably inoculated the remaining melt of eutectic compn. F. W. Fink

General principles of alloy making by fusion. A. Portevin. *Rev. mét.* **36**, 429–45(1939); cf. *C. A.* **33**, 8549³.— Alloy prepn. is reviewed from a broad standpoint embracing the equipment employed, means of protection from oxidation, losses involved, heat reaction taking place and the selection of optimum compns. The article does not give details. J. D. Gat

Elastic modulus of metallic alloys. L. Guillet, Jr. *Rev. mét.* **36**, 497–521(1939); *Génie civil* **116** 29–32

(1940).—Variations in the elastic modulus of several alloys were studied by means of a LeRolland-Sorin app. Elastic modulus of pure metals is connected with their at. vol., high limits to be found in elements having small at. vols. and high m. ps. When elastic modulus is detd. in solid-soln. alloys close to the pure metals, it varies linearly with the compn. In case of intermetallic compds. 2 possibilities are encountered; they behave either as pure metals or have a much higher modulus of elasticity indicating a strong chem. bond. A study of compn. does not permit the detn. of its probable modulus of elasticity. The subject is treated in considerable detail both from the scientific side and in description of app. used in detns.
J. D. Gat

Magnetic detection of flaws in metallic alloys. J. Fluvot. *Génie civil* **115**, 333–7, 355–7(1939).—A discussion with 1 drawing, 11 photographs and 6 spectrographs.
Ann Nicholson Hird 3

Influence of heat treatment and deformation upon the properties of a few hardenable aluminum alloys. H. Unckel. *Metallwirtschaft* **19**, 37–44(1940).—Hardenable Al alloys contg. Cu, Mg, Mn, Fe and Si were investigated. With about 3.9–4.2% Cu, 1.55–1.57% Mg, 0.27–0.31% Fe, 0.26–0.27% Si the most favorable temp. for homogenizing is between 490 and 500°, with a time range of 10 to 60 min. depending upon the thickness of the specimens. Longer heat-treatment is without further effect, even upon grain size. Reduction to a given thickness by 2 heavy rollings gave a product of about the same properties as reduction to the same thickness by 12 light rollings. In alloys of the duralumin type, plastic deformation between quenching and hardening increased the limit of stretch and lowered the ultimate strength. Photomicrographs and x-ray diagrams are shown. H. Stoertz 4

The influence of alloying elements on the crystallization of copper. II. Large additions and the part played by the constitution. L. Northcott. *J. Inst. Metals* **65**, Advance copy, No. 857, 32 pp.(1939); cf. *C. A.* **32**, 3317⁹.—The binary systems of Cu with Al, Mg, Mn, Ni, P, Pb, Sn and Zn were studied. The length to which crystals grew after being cast against a water-cooled chill was measured and this length was plotted on the constitution diagram. In general, the amt. of superheat of the melt before casting had little effect on the contour of this line representing crystal length. This line was influenced by absorption of the alloying elements, freezing range and the 2nd phase (solid soln. or eutectic). In the Cu-Al system longest crystals occurred at 0% Al, 8% Al (eutectic) and 12% Al (with the max. m. p. of an intermediate solid soln.). The Cu-Mg and Cu-P diagrams were similar with respect to the crystal length curves, pure Cu giving the max. length crystals, with another high point occurring at the max. soly. of Cu in the 2nd phase (3% Mg, 2% P) and a steep max. at the eutectic (10% Mg, 9% P). Cu-Mn had max. crystal length at 0% and 33% Mn (with a min. m. p.). The Cu-Ni crystals were uniformly small. A peak occurred in the Cu-Pb curve at 50% Pb for which no explanation was offered, although segregation was noted particularly in this 50:50 compn. The plot of the crystal lengths in the Cu–Sn system showed the max. for 0% Sn, with a min. at 0.5% Sn and irregular increasing to 25% Sn. In the Cu–Zn system maxima were at 0, 38–50, 60, 87 and 100% Zn. Every max. was sepd. from the next by a sharp drop to a min. 6 references. J. N. Lynn 5 6

The cobalt-nickel-silicon system between 0 and 20 per cent silicon. Arthur C. Forsyth and R. L. Dowdell. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. 1170, 15 pp.(1940).—A partial Co-Ni-Si constitution diagram below 19.3% Si is presented. The method used in drawing this diagram shows clearly the liquidus, solidus and solid transformations for the temp. ranges investigated. Ni and Co seem to replace each other in these alloys, producing only 2 phases in stable equil. The α-solid soln. alloys are all capable of being wrought and may find industrial application. Their properties are now being investigated. Alloys above 10% Si are brittle but have excellent corrosion resistance and other properties that are being exploited. Alloys contg. α-solid soln. are ferromagnetic. C. L. Mantell 7

Changes in damping capacity during annealing of α-brass. John T. Norton. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. **1168**, 10. pp(1940).—The present expts. confirm the fact that when metals are tested at comparatively low frequencies, the principal cause of energy dissipation is local or general plastic deformation. In cold-worked metals, the internal stress system is an important factor in the production of localized plastic flow. The relief of internal stresses by annealing reduces the damping to a low value and the value is low over a considerable range of applied stress. At the recrystn. temp., the damping capacity shows little change, provided the applied stress is well within the so-called elastic range of the material. Considered from the point of view of a metallurgical tool, the damping capacity is a sensitive indicator of internal stresses but is relatively insensitive to changes in grain size. C. L. Mantell 8

Recovery and recrystallization in long-time annealing of 70-30 brass. S. E. Maddigan and A. I. Blank. *Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. **1166**, 21 pp.(1940).—An investigation has been made of the processes of recovery and recrystn. during low-temp. annealing of cold-worked 70-30 brass. Two annealing temps. were used, one slightly above and the other slightly below the accepted recrystn. temp. After various annealing times up to 2740 hrs., microscopic studies were made in addn. to tensile-strength measurements and very sensitive cond. measurements. The process of softening seems to be divided into 2 parts: a stage of pure recovery preceding any microscopic evidence of recrystn. and a 2nd state in which recrystn. can be seen under the microscope and softening is probably a combination of recovery and recrystn. The boundary between these stages was fixed at almost identical times by all the methods of investigation; i. e., microscopic, tensile strength and cond. Just previous to the 2nd stage, an anomalous drop in cond. sometimes occurs, which may be due to nucleation. A 2nd cond. anomaly is also observed, which may be explained by grain growth of new crystals in a softened but not completely recrystd. matrix. For lower degrees of reduction, evidence is advanced to show that grain growth can occur before recrystn. The temps. used here are well below those used for strain-annealing and also below those at which so-called "abnormal" grain sizes are generally observed. C. L. Mantell 9

Protective coatings for iron and steel. J. C. Hudson. *Iron & Coal Trades Rev.* **139**, 751–2(1939).—The work of the Corrosion Committee (British) is reviewed briefly and the prepn. of surfaces and the best methods of painting iron and steel as a protection against corrosion are described. I. Hartmann

Corrosive effect of "heavy gasoline" on the white metals of carburetors. Gilbert Juge-Boirard. *IIme Congr. mondial pétrole* **3**, Sect. 4, 712–20(1937)(in French).—The components of "heavy gasoline," a French mixt. of gasoline and alc., were tested for their corrosive effects on the white metals usually employed in carburetors. Usually the mixt. separates into two layers; an upper layer contg. almost all the gasoline, traces of alc., and traces of water. This layer has no action on the metal. The lower layer consists of most of the alc., all the coloring material, traces of gasoline and almost all of any water that may be present. This layer attacks the metal. The corrosive factors are the water carried by the alc., and impure coloring matter. Denaturants for the alc. may also cause corrosion. Tests on metal-strip samples are shown in diagrams. E. J. Mahler

Corrosion of iron in water. Effect of small concentrations of sodium silicate. Dante J. E. Veronelli. *Industria y quim.* **2**, 182–91(1939).—A review of the essential

facts and decisive factors operative in the corrosion of Fe in H_2O is followed by the description of original expts. with H_2O contg. small concns. of Na_2SiO_3. Such addns. lead to an increased pH and an even greater reduction of corrosion; the Fe is given a protective $FeSiO_3$ film, even after the metal has been taken out of the soln. and placed in pure H_2O. With increasing temp. Fe corrosion increases at a slower rate in the soln. than in pure H_2O. The effect of Na_2SiO_3 is more pronounced in H_2O contg. large amts. of dissolved O and in distd. H_2O than in ordinary H_2O. 38 references. A. H. Krappe

High lead-low tin alloys as coating materials. Joseph B. Kushner. *Metal Ind.* (N. Y.) **37**, 511–12(1939).—A series of Pb-Sn alloys in which Sn ranges from 0.5–10% are used for coating materials and as a lubricant for wire drawing. C. B. Jenni

Hardness testing of light-gage sheet steel by scratch resistance. James A. Townsend. *Iron Steel Engr.* **16**, No. 9, 22–7(1939).—A scratch method for measuring the hardness of sheet metal was used. Test results showed a definite trend toward lower torque-resistance values for higher hardness numbers, B-90 to B-100 Rockwell, as compared with a greater resistance to scratch penetration in the softer samples using a const. wt. This trend points toward a definite relation between the scratch penetration and direct indentation methods of comparative hardness measurements. A scratching point with a wider, more rounded shape was recommended for trial before rejecting the project as unworkable. C. B. Jenni

X-ray analysis of corrosion products from galvanized sheets. F. R. Morral. *Trans. Electrochem. Soc.* **77**, 8 pp. (preprint)(1940).—X-ray diffraction analysis of corrosion products shows the presence of ZnO, $ZnCO_3$, $2ZnCO_3 \cdot 3Zn(OH)_2$ and other basic Zn salts. The compn. of the corrosion products depends on the compn. of the Zn coatings and on the environment to which they have been exposed. C. G. F.

Corrosion by the products of combustion of town gas. Frank Taylor and James W. Wood. *Engineering* **149**, 58–9(1940).—The corrosion of several metals was investigated. Each material was in the form of a 1-in. tube, fitted at the top with a water jacket and insulated along the rest of its length. The water vapor produced from the gas burned at the bottom of each was partially condensed on the water-cooled section of the tube. This condensate, which with dissolved S and N acids, formed the corroding medium, ran down the tube to hotter regions where reëvapn. and concn. occurred. The corrosion deposits were allowed to accumulate for 32 days and then the tubes were examd. Solder-coated and tinned Cu withstood the conditions best, but even they do not afford permanent protection against corrosion. Te-Pb and chem. Pb also proved very resistant to attack, the formation of a protective coating of Pb sulfate being an important factor. If S compounds were removed from the gas, Pb would be rapidly corroded. Al was investigated in three different purities, 99.95%, 99.5% and 98.5%. With each specimen heavy corrosion deposits formed locally in the tubes, but the purest specimen gave only half the corrosion of the other two. Cu and brass behaved similarly to Al in giving voluminous deposits. With the S content of the gas reduced from 22 to 5 gm. per 100 cu. ft., however, the time taken for a deposit sufficient to block up the tubes increased threefold. With mild steel, reduction of the S content reduced corrosion by half. With Monel metal it was found that the Ni had been removed preferentially from the metal, very little of the Cu having been removed; Ni must be classed as poorly resistant to corrosion under these conditions of attack. I. Hartmann

The protection of the Bakman apparatus from corrosion. E. M. Khanin. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 10, 40–2(1939).—The use of acid-resisting cement and various protective coverings in preventing corrosion of *app. for chlorinating lime* is discussed. H. M. Leicester

The protection of condensers from corrosion. V. V. Samokhin. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 10, 43–5 (1939).—The condensers are painted with a mixt. of 1000 g. Bakelite lacquer, 200 g. kaolin, 50 g. Al powder, 150 g. EtOH and 50–60 g. of a covering pigment. From 4 to 6 coats are applied, the tubes being heated at 120–50° between each application to polymerize the Bakelite. The coeff. of heat transfer is hardly changed by this treatment, though if the Al powder is omitted from the mixt., this coeff. is greatly decreased. The surface is stable to 250°, withstands a blow of 50–60 kg./sq. cm. and has a Brinell no. of 35–40. Details of applying the coats are given. H. M. Leicester

Corrosion-resistance properties of chromium-manganese steels. Albert L. de Sy. *Rev. mét.* **36**, 389–99(1939).—Acid corrosion study of a number of Cr-Mn steels with or without Ni addns. up to 2% and with C around 0.1% indicated their susceptibility to intercryst. corrosion on heating at moderate temps. which result in the formation of a ferritic phase. This phase is rapidly attacked by the boiling 10% H_2SO_4 + 10% $CuSO_4$ soln. Transformation of austenite into ferrite on drawing can be clearly shown by electrolytic etching in 10% CrO_3. The 18-8 type of this steel is more corrosion resisting than the 15–12 or 15-9 with Ni addns. J. D. Gat

The corrosion resistance of welded light alloys. I. Brenner. *Aluminum and Non-Ferrous Rev.* **4**, 334(1939).—The samples were immersed in a 3% NaCl soln. contg. 0.1% H_2O_2 and were extended for two years. Pure Al and alloys which were not supersatd. with compds. forming mixed crystals were about as resistant to corrosion as the nonwelded metals. This was also true of Al-Mn and Al-Mg-Mn alloys contg. an amt. of Mn greater than the soly. limit at room temp. Hardened alloys of Al-Mg-Si and Al-Cu-Mg showed electrochem. corrosion at a certain distance from the welding line. If they were hardened again the electrochem. corrosion did not take place. Plated Al-Cu-Mg and Al-Mg alloy sheets showed superior resistance to corrosion after welding. Iver Igelsrud

First progress report—joint investigation of continuous welded rail. Herbert F. Moore, Howard R. Thomas and Ralph E. Cramer. *Am. Ry. Eng. Assoc., Bull.* No. 411 (1939); *Univ., Illinois Bull., Eng. Expt. Sta., Reprint Ser.* No. 13, 29 pp.(1939).—Lab. investigation in progress includes: Etch tests to see whether any "flakes," laps, holes, burns, inclusions, cracks or any other type of defect have resulted during welding and subsequent cooling, and if so, where these defects are located in the joint. Hardness surveys of the metal in the weld, in the adjacent rail and in the transition zone between weld metal and rail metal. Survey of typical cryst. structure in weld, rail and transition zone by means of the metallurgical microscope. Chem. analysis of the steel in the rail, in the weld and in the transition zone. Mech. tests of specimens cut from weld metal, rail metal and transition zone; the tests include tension tests, impact tests and fatigue tests. Rolling-load fatigue tests of full-sized specimens of welded rail to det. the possibility of internal-fissure development in welded joints, the fatigue strength on flexure of welded joints and the likelihood of damage to the web of the rail near the weld. Drop tests and bend tests of full-sized rail joints. Up to the present time 104 test rails (welded by 2 types of fusion gas welding, thermite welding, elec. flash welding and gas-heated pressure welding) have been supplied. Results to date of the various tests are discussed. 52 references. C. B. Jenni

Atomic-hydrogen arc welding solves difficult problems. W. E. Wilson. *Gen. Elec. Rev.* **42**, 427–31(1939).—Atomic-H arc welding differs from ordinary arc welding: The H arc is maintained between 2 electrodes (rather than between one electrode and the work); the H arc is made to occur entirely in an atm. of H_2 to produce atomic H which with the arc is directed on the work to perform the welding operation. The recombination, $2H = H_2$, results in a high temp. arc fan and especially good heat transfer. Since H arc is independent of the work, it can be moved instantly at will. Welded joints are ductile, strong, dense and free from pinholes. Many applications are cited, among these Cr steels, Al, hard surfacing, fine wire mesh. C. G. F.

Automatic atomic-hydrogen welding of steel. J. T. Catlett. *Iron Steel Engr.* **17**, No. 1, 25–32(1940).—A brief

history of the development of welding. An explanation is given of the atomic-H welding process, including hand welding and the variables controlled by the operator, the single-arc automatic welding equipment and the methods used to control the variables; and the multiple-arc equipment and the methods of application to the tube welding problem. The use of dissocd. NH_3 as a substitute for H is discussed. Charts of welding data are developed for the single-arc, the 3-arc, the 6-arc, the 10-arc and the 15-arc equipment, giving welding speeds in ft. per hr. and in tons per hr., and welding costs per ft. and per ton using either H or dissocd. NH_3. C. B. Jenni

Use of the weld-bend test for structural steel. Eduard Houdremont, Karl Schönrock and Hans J. Wiester. *Stahl u. Eisen* **59**, 1241–8, 1268–73(1939).—In the weld-bend test a longitudinal seam is welded in the center of a 700 × 200 × 50-mm. plate, which is then bent longitudinally so that the welded seam is on the outside of the bend. Cracks form through the weld as the angle of bend is increased; the angle of bend at which a crack extends across the whole width of the specimen is taken as a measure of the weld sensitivity of the structural steel. Thinner plates may also be tested in this way. Weld sensitivity was decreased (larger angle of bend) by preheating the plate before welding and, of course, by annealing after welding. Fine-grained steels were less weld-sensitive, but this was attributed more to the effect of the finely distributed inclusions in obstructing notch propagation than to the effect of the fine grain *per se* as revealed by the McQuaid-Ehn test. The angle of bend was increased by raising the temp. a rise to 100° having a very decided effect. The test is highly recommended for testing weld sensitivity. S. Epstein

Apparatus for flotation concentration of ores. Hugh W. Coke. U. S. 2,184,115, Dec. 19. A flotation app. includes a plurality of cleaner cells, a feeder for feeding a selective flotation reagent to one or more of the cleaner cells, an elec. motor for driving the feeder, means for delivering air to aerate the cells, a valve for each cell to control the delivery of air thereto, means for opening the circuit through the motor intermittently to stop the feed of the reagent to the cells, and means for closing the air-controlling valves during the feeding of the reagent and for opening the valves when the motor circuit is open.

Ore-concentrating apparatus (with a plurality of sluice boxes). Wm. L. Opie (to Sierra Leone Development Co. Ltd.). U. S. 2,184,226, Dec. 19. Various structural, mech. and operative details.

Trough for concentrating metals from gang. Bianca A. Miller. U. S. 2,183,971, Dec. 19. Various structural details.

Treatment of ores or the like containing tantalum and columbium. Joseph P. Leemans (to Soc. générale métallurgique de Hoboken). U. S. 2,183,517, Dec. 12. A process for the treatment of primary materials contg. Ta and Cb involves a reduction of the primary material by means of at least one of the metals Al, Ca, Mg alloyed with at least one of the metals whose alloying reaction with the reducing elements develops heat so that the metallicthermic power of a given quantity of the reducing elements is smaller in the obtained alloy than in the same quantity in the elementary state, thereby selectively reducing the Cb and obtaining an alloy in which the ratio Cb:Ta is higher than in the primary material, and a slag in which the ratio Ta:Cb is higher than in the primary material.

Titanium concentrates from ores. James E. Booge (to E. I. du Pont de Nemours & Co.). U. S. 2,183,365, Dec. 12. For producing a substantially Fe-free TiO_2 concentrate, a titaniferous ore is heated in the presence of a gaseous oxidizing medium such as air to about 500–1000° and the resultant oxidized ore is then subjected to the action of gaseous HCl at 600–800° in order to convert Fe present to $FeCl_3$.

Reducing ores such as those of iron. Frank Hodson and Paul A. Hirsch. U. S. 2,184,300, Dec. 26. App. is described, and a process which involves introducing pulverulent ore into a violently turbulent and upwardly flowing column of reducing gases, regulating the velocity of the gases so as to carry the ore upwardly and maintain it in suspension until it is reduced to metal, maintaining the temp. of the gases below the fusion temp. of the metal, and sepg. the metal from the gases.

Apparatus (with tilting buckets) for use in mining and amalgamating gold. Joseph H. Thornton. U. S. 2,184,447, Dec. 26. Various structural, mech. and operative details.

Apparatus, with a rotary furnace, suitable for melting iron or steel, etc. Aubrey J. Grindle (to Alwin F. Pitzner). U. S. 2,184,297, Dec. 26. Various structural, mech. and operative details.

Furnace and tube still apparatus suitable for oil heat-treatments. Cecilio L. Ocon. U. S. 2,184,465, Dec. 26. Various structural and operative details.

Apparatus for washing gases from metallurgical furnaces, etc. Charles M. Gerhold (to Louise H. Gerhold). U. S. 2,184,185, Dec. 19. Various structural and operative details.

Smelting zinc-containing material in shaft furnaces. Hüttenwerke Siegerland A.-G. Brit. 508,606, July 4, 1939. See Fr. 834,408 (*C. A.* **33**, 3745[5]). The gas conduit from the blast furnace up to the gas purifier consists of vertical pipes only, or pipes steeply inclined to the horizontal. Between the furnace and the fine purifying plant dry separators or "whirlers" are disposed, the size and no. of which are such that in the same the gas is cooled

and the heavy Fe-contg. dust is almost completely sepd. and in the subsequent "fine purification" a dust rich in Zn and poor in Fe may be obtained. 1

Simultaneous production of alumina cement and pig iron in a blast furnace. Stevan Ruzicka. U. S. 2,184,318, Dec. 26. A process is employed which involves subjecting a blast-furnace charge contg. Fe, bauxite, a carbonaceous material selected from a class consisting of petroleum coke produced at high-coking temp. and an artificial charcoal resulting from subjecting pulverized charcoal and a cokable binder to the action of a coking-oven retort at temps. between 500° and 1200°, to a blast-furnace reduction for producing molten iron and alumina cement. 2

Radiation pyrometer suitable for use with molten metal baths. Louis O. Sordahl (to United States Steel Corp.). U. S. 2,184,169, Dec. 19. Various structural details.

Magnesium. Magnesium Elektron Ltd. Brit. 508,647, July 4, 1939. In reducing oxidic Mg compds., e. g., calcined magnesite or dolomite, at a high temp., preferably *in vacuo*, by CaC_2 in stationary retorts, rotary furnaces, shaft furnaces, etc., to produce Mg vapors and a more or less pulverulent reaction residue consisting mainly of CaO and C, the solid reaction residues are caused to agglomerate or sinter together in the course of the reaction by insuring the presence in the reaction mixt. of a substance or mixt. adapted to produce such agglomeration. SiO_2, e. g., powd. quartz, and (or) Al_2O_3 are preferable addns. The SiO_2 and Al_2O_3 may be calcined clay. SiO_2 may be added in amt. sufficient to form di- or tri-Ca silicate or a substance of intermediate compn. and Al_2O_3 in amt. sufficient to form mono- or tri-Ca aluminate or a substance of intermediate compn. The SiO_2 may be added as Mg silicate. The Mg silicate and CaC_2 may be in proportion to yield di-Ca silicate. Cf. *C. A.* **33**, 2473[9]. 3

Converting magnesium dust into compact metal. Konrad Erdmann (to American Magnesium Metals Corp.). U. S. 2,183,392, Dec. 12. An arrangement of app. is described, and a process which involves vaporizing Mg from magnesium dust after admixt. with the ground residue of a previous similar operation and, briquetting the mixt. under high pressure, and condensing the vapor evolved. 4

Recovery of lead from waste sludge obtained in tetraethyl lead manufacture. Robert B. Erickson. U. S. 2,184,520, Dec. 26. Sludge contg. Pb oxide and NaCl is leached to reduce the NaCl content to below about 2.5%, and the treated sludge, together with coke, is charged into a continuously operated blast furnace in which molten Pb accumulates in the furnace pot with an overlying zone of molten slag, the slag being tapped off and the reduced molten Pb being withdrawn from the bottom of the furnace pot. 5

Removing zinc from lead and lead alloys. Gustave E. Behr (to National Lead Co.). U. S. 2,183,420, Dec. 12. The metal to be purified is melted and agitated with added NH_4Cl, without addn. of Cl, and the $ZnCl_2$ skim formed is removed. 6

Zinc recovery from zinc oxide. Jesse O. Betterton and Melville F. Perkins (to American Smelting and Refining Co.). U. S. 2,183,535, Dec. 19. A charge comprising ZnO and a carbonaceous reducing agent such as coke is subjected to a flash reduction and the resulting gaseous products contg. Zn vapor are intermixed with a cold stream of CO without prior conditioning, to quench the Zn vapor to a temp. at which reactions conducive to Zn reoxidation proceed only at "harmless" rates, and Zn is recovered from the quenched vapor. App. is described. 7

Extrusion press suitable for use in making metal products. Charles W. Krause (to Forging and Casting Corp.). U. S. 2,184,048, Dec. 19. Various structural details and details of special alloy steels used. 8

Cutting metals such as steel plates with an oxidizing jet. Harry E. Rockefeller and John H. Rountree (to Linde Air Products Co.). U. S. 2,184,562, Dec. 26. A process of cutting metal, where an oxidizing jet is advanced relatively to the metal to be cut at such a speed that the resulting kerf walls are left irregular and rough, involves concurrently advancing a smoothing jet of oxidizing gas along and substantially aligned with the central plane of the kerf at a point behind the first jet to trim a thin layer from one of the walls, the smoothing jet having a cross section substantially equal to the max. deviation of the irregular wall from a plane surface. 9

Cutting metal bodies such as thick steel slabs at high speed. Roger S. Babcock and John M. Gaines, Jr. (to Linde Air Products Co.). U. S. 2,184,561, Dec. 26. App. is described, and a method of cutting metallic bodies at high speed, which comprises heating the metal to the kindling temp., and progressively applying oxidizing gas upon the heated surface in such a manner that a portion of the oxidizing gas produces a deseaming puddle on the surface of the metallic body so as to preheat the metal effectively for complete severing, and the remainder of the oxidizing gas progressively penetrates through the parts of the metallic body at the rear of the puddle to produce a kerf therein.

Use of oxygen jets for forming shaped edges on steel plates or the like. Herbert H. Moss (to Union Carbide and Carbon Corp.). U. S. 2,184,560, Dec. 26. A low-velocity O machining jet is applied, and behind this there is also applied, simultaneously and progressively, a high-velocity O cutting jet.

Presses for extruding metal. Geo. A. V. Russell and Imperial Chemical Industries Ltd. Brit. 508,557, June 30, 1939.

Manufacture of chilled hollow balls such as those of steel by centrifugal force. Sinsaku Nakagawa (to Toyo Tokushu Imono K. K.). U. S. 2,184,257, Dec. 19. Various details of app. and operation.

Rolls for rolling mills. Metal Carbides Corp. Brit. 508,674, July 3, 1939. Divided on 506,728 (*C. A.* **34**, 3623). At least the working surface of a rolling-mill roll is made of a cemented compn. consisting of hard metal carbide particles and metallic cementing medium therefor W carbide is preferred but carbides of Ta, Ti, Cr, Mo or V may be used in place of or in addn. thereto, while Co or Ni is the preferred cementing medium though Fe, Mn, Cr, Mo, Cu, Al, Be, etc., may be used.

Ferrous metal piston ring. Walter J. Six. U. S. 2,183,358, Dec. 12. The rings are heated to above the crit. temp., and after partially quenching the hardened rings they are expanded and their shape is changed to the desired permanent form below the crit. temp. and before the quenching is completed. App. is described.

Apparatus for heat-treating and shaping metal clutch disks, etc. Reinhold C. Zeidler (to Borg-Warner Corp.). U. S. 2,183,300, Dec. 12. Various structural, mech. and operative details.

Heat-treatment of light metals and alloys. Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler. Brit. 508,541, June 29, 1939. In a process for regulating and maintaining the activity of alkali nitrate- and (or) alkali nitrite-contg. melt baths for the heat-treatment of the metals, especially Al and its alloys, the formation or accumulation of disturbing quantities of alk. compds. is counteracted by the periodic or gradual addn. of acid salts, acid-yielding compds. or other alkali-fixing compds. in quantities sufficient to render the alk. compds. nondetrimental. The addns. may be alkali or NH_4 metaphosphates, acid phosphates or pyrophosphates, neutral NH_4 salts that are decompd. by the alk. compds. formed, the NH_4 radical combining with the acid radical of the compds. added, or alkali dichromates, which are introduced in admixt. with other bath constituents, e. g., alkali nitrate, for the mixt., which preferably contains at least 5 parts of the other salts, e. g., alkali nitrate, for each part of alkali dichromate. The salt mixt. is introduced preferably at not more than 100° above the m. p. of the bath.

Surface-hardening shafts, axles and like long lengths of material. Adolf Messer. Brit. 508,680, June 29, 1939. A blowpipe having a simple nozzle for heating the shaft, etc., with a quenching device in close lateral spaced relation thereto, i. e., as close as mechanically practicable, for applying quenching liquid, e. g., as a spray, to the shaft, etc., is traversed along the shaft, etc., in a longi-

tudinal direction relatively thereto and during rotation thereof. 1

Cover suitable for use in annealing metal sheets or coils. Carleton C. Clark (to American Rolling Mill Co.). U. S. 2,183,785, Dec. 19. Various structural details.

Metallic product containing tungsten, nickel and copper. Colin J. Smithells (to General Elec. Co. Ltd.). U. S. 2,183,359, Dec. 12. See Can. 384,709 (*C. A.* **34**, 1302[8]).

Desulfuring pig iron. Heinrich Koppers G. m. b. H. (to Heinrich Koppers' Industrieele Maatschappij N. V.). Brit. 508,539, June 28, 1939. C and soda are added in a liquid fused state to the molten Fe while it is being poured or transferred from 1 vessel to another during processing. The soda is preferably fused in a vessel the walls of which consist of C or a C-contg. material. A trough with a discharge opening may be used for mixing the Fe with the C-soda mixt. The alk. silicate formed and into which the S impurities are withdrawn may be completely removed from the surface of the fused metal by means of a pistonlike body covered with fireproof material that is lowered into the vessel from above until the surface of the Fe bath is in the same plane as the outlet of the vessel, whereupon the slag, or so much thereof as does not flow off unaided, can be removed by scraping or blowing off, e. g., by means of superheated steam. Cf. *C. A.* **33**, 2470[7]. 2

Cast iron. Wm. J. Priestley (to Electro Metallurgical Co.). Brit. 508,540, June 29, 1939. Cast Fe of increased strength is made by adding 1–16 oz. of an unbonded intimate mixt. contg. 25–75% C, the remainder consisting of 1 or more of Si, Zr, Fe-Si or Si-Zr, to each 100 lb. of the cast Fe and casting the melt. The C may be graphite. Cf. *C. A.* **33**, 1651[9]. 3

Steel. Maximilian von Schwarz. Brit. 508,465, June 26, 1939. Divided on 508,375 (see below). Constructional parts liable to the destructive effects of water-hammer from wet steam or similar erosion are made of a steel alloy contg. C 0.2–2, Cr 6–30 and Mn 2–12%. One or more of the carbide-formers, Mo, W, Ti and V, may be added in the proportions usual for such purpose. In Brit. 508,375, June 26, 1939, the parts are made of steel of eutectoid structure. An erosion-resistant layer may be formed on the parts by carbonizing a hypoeutectoid steel to produce the aforesaid structure. Cf. *C. A.* **33**, 1650[9]. 4

Casting steel ingots. Lewis B. Lindemuth. U. S. 2,183,576, Dec. 19. A layer of ground cork impregnated with Na silicate is applied to the top of metal in a mold to retard cooling. 5

Alloy steels. Wm. H. Hatfield and Joseph F. Bridge. Brit. 508,710, July 5, 1939. A low-C austenitic Cr-Ni-Mo steel comprises C up to 0.20, preferably below 0.10, Ni 10–30, Cr 15–35 and Mo 5–15%. Si and Mn may be present in the usual amts. The steels have very high tensile strength at high temps. and are resistant to the action of corrosive gases. 6

Steel alloys. Fried. Krupp A.-G. Brit. 508,619, July 4, 1939. Articles that, after being welded, are subjected without subsequent high-temp. heat-treatment to attacks by corrosive agents are made from corrosion-resistant austenitic or austenitic-ferritic Cr-Mn steel alloys contg. 0.05–1.5% N. The alloys preferably contain C 0.01–0.3, Cr 9–25, Mn 6–25 and N 0.07–0.35%. 7

Corrosion-resistant steel alloys. Russell Franks (to Electro Metallurgical Co.). U. S. 2,183,715, Dec. 19. Alloy ferritic steels suitable for lamination with other steels, etc., contain Fe together with Cr 15–35, Mo 1–5, Mn 0.01–3, Si 0.01–3, C 0.01–0.35, N 0.01–0.5% and Cb in an amt. at least 4 times the C content but not exceeding 8 times the C content by more than 1.5%. 8

Steel-alloy tubing suitable for machining. Harry W. Hudson (to National Tube Co.). U. S. 2,184,498, Dec. 26. A method for use in the manuf. of cold-drawn Ni-alloy steel tubing contg. C less than 0.25, Ni 2–5 and Mn 0.3–0.6%, together with Fe, involves heating the tubular blank to a temp. substantially above the upper crit. point, holding the blank at the temp. for approx. an hr., pptg. the carbides along the cleavage planes of the austenitic crystals by rapidly cooling the blank in the atm., and finally elongating the constituents of the steel structure axially of the tubular blank by cold-drawing the same, thereby producing a tubular steel blank which is freely machineable. 9

Forming pens from stock metals such as chrome steel. David Kahn (to David Kahn, Inc.). U. S. 2,183,572–3, Dec. 19. Various details of manuf. of ball point pens.

Alloys. Hall & Pickles Ltd., John H. Russell and Alexander M. C. Murphy. Brit. 508,319, June 29, 1939. A high heat-resisting alloy for an elec. resistance element of the high Ni-high Cr type without Fe or with Fe not in excess of 30% contains 1–10% Cb together with the usual deoxidant(s), e. g., Ca, Al, Ti, Zr, Ce. The Cb may be added as a ferro alloy contg. 50–60% Cb. A typical alloy contains Ni above 50, Cr 10–30, Fe to not more than 30 and Cb up to 10%.

Hard alloys. Tool Metal Manufacturing Co. Ltd. Brit. 508,662, July 4, 1939. A mixt. more than 50% of which consists of W carbide (I) and Ta carbide (II), and the remainder (more than 5%) of 1 or more carbides of Ti, Mo, V, Cb, Zr and Th, is pressed and sintered at 1400–1700° to form a hard alloy of high m. p. without auxiliary metal. The carbides of Ti, etc., preferably amount to 10–20%. Examples are (1) I 70, II 15 and Ti carbide 15, and (2) I 50, II 30, Mo carbide 10 and V carbide 10%, pressed and sintered at 1550 and 1450°, resp.

Alloys for jewelry, rings, etc. W. C. Heraeus G. m. b. H. Brit. 508,669, July 4, 1939. These contain Au 25–55, Pd 2–6, Ag 10–30 and Zn 9–25%, the remainder being at least 5% of Cu. Alloys in which the Cu:Zn ratio is approx. 2:1 are preferable. Specified alloys are Au 33.3, 41.7, 37.5; Pd 3.0, 3.0, 4.0; Ag 17.0, 21.0, 18.0; Cu 30.0, 21.3, 27.0, and Zn 16.7, 13.0, 13.5%.

Dental alloy. Wilhelm Krezdorn. Ger. 684,982, Dec. 9, 1939 (Cl. 40*b*. 17). The composition of the alloy is Cr 51–70, Pd or Pt 1–10, of one or more of the metals W, V, Ta, Re 0–6%, the remainder Ni.

Aluminum alloys suitable for floats of measuring instruments. Otto Dahl and Herbert Dallmann (to General Elec. Co.). U. S. 2,183,391, Dec. 12. An alloy subject to oxidizing conditions and contact with Hg is formed of Al together with Cu 0.3–1.5, Mn over 0.3 and Mg 0.5–4% (the total of Cu and Mn being not over 5% of the alloy).

Copper-zirconium alloys. N. V. Philips' Gloeilampenfabrieken. Brit. 508,330, June 29, 1939. A wire-shaped conductor, e. g., a high-voltage conductor, telephone or telegraph wire, trolley wire or enameled wire, having a tensile strength at least 1.5 times that of pure Cu and a sp. resistance approx. that of Cu consists of a Cu-Zr alloy contg. 0.02–5% Zr.

Lead alloys. Pirelli-General Cable Works Ltd. and Giuseppi Martinez. Brit. 508,394, June 30, 1939. Alloys suitable for continuous extrusion contain Sb 0.5–1%, a small quantity of Fe, with or without a small quantity of Cu up to 0.05%, the Fe being 0.001–0.05% when Cu is present and 0.001–0.02% when Cu is absent, and Pb the remainder.

Lead alloys. Pirelli-General Cable Works Ltd. and Giuseppe Martinez. Brit. 508,604, July 4, 1939. Alloys suitable for continuous extrusion, e. g., for the production of Pb pipes or elec. cable sheaths, comprise Cd 0.2–2, with Sb 0.25–1 or Sn 0.5–2, and Fe 0.001–0.05, with or without Cu not exceeding 0.08%, the remainder being Pb.

Treating lead alloys. Herman L. Smith (to American Smelting and Refining Co.). U. S. 2,184,535, Dec. 26. For increasing their resistance to drossing under repeated meltings and castings, Pb-base alloys, such as type metal, are treated while molten with a carbohydrate, a reducing gas such as H, and a metallic deoxidizing agent.

Corrosion-resistant chromium-manganese-iron alloys. Alfred Kropf. U. S. 2,184,305, Dec. 26. Alloys suitable for use as substitutes for German silver contain Fe together with Mn 7–50, Cr 6–25, Cu 0.5–10 and C up to 0.4% (the Mn content being in excess of the Cr content).

Coating steel wire to prevent corrosion. Elgin C. Domm (to National-Standard Co.). U. S. 2,184,179, Dec. 19. Steel wire is coated with a Pb-Sb alloy, drawn to reduce its cross section while leaving a continuous coat-

ing of the alloy and then provided with an electrodeposited Cu coating thin enough to alloy throughout with the Pb-Sb alloy at atm. temp. or the temp. of vulcanization, and further provided with a vulcanized-on rubber coating. Cf. *C. A.* **34**, 947[5].

Pipe welding and heat-treatment. Harry B. Smith and Geo. A. Dolan. U. S. 2,184,534, Dec. 26. Elec. app. is described, and a process of butt-welding metallic members together which consists in applying windings around the adjacent parts of the members, passing a. c. through the windings to establish alternating electromagnetic fields uniformly around the parts to induce preheating currents in the parts, then arc-welding the joint between the members while the windings are still in place, and when the welding is completed immediately applying the current again to the windings, and controlling it so as to normalize the weld.

Welding rod and hard overlays produced with it. John T. Eash and Thomas J. Wood (to International Nickel Co.). U. S. 2,184,518, Dec. 26. A welding rod for producing hard overlays by welding contains Fe together with C about 2–4, Si about 0.25–2, Ni about 2–5, Cr about 0.25–3, Mn about 0.1–1.5, S not over 0.2, P not over 0.3, a deoxidizer such as Al or Ca-Li about 0.5, and B about 0.5%. Such a welding rod is suitable for producing hard overlays on cast iron, etc.

10—ORGANIC CHEMISTRY

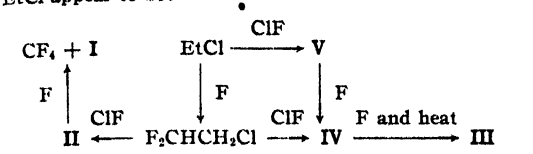
CHAS. A. ROUILLER AND CLARENCE J. WEST

Production of organic compounds from the waste products of pyrolysis and cracking of petroleum. M. A. Dalin. *Org. Chem. Ind.* (U. S. S. R.) **6**, 485–9(1939).—A discussion of the production of EtOH, Et_2O, Me_2CO, chlorinated solvents and other products from the waste satd. and unsatd. hydrocarbons as based chiefly on American practice. Chas. Blanc

Inhibition of the hydrogenation of ethylene by nitric oxide. H. D. Burnham and R. N. Pease. *J. Am. Chem. Soc.* **62**, 453(1940).—The ratio of the times required for 16% conversion of the C_2H_4 in mixts. of 180 mm. C_2H_4 and 540 mm. H without and with 20 mm. NO, resp., is 0.79 at 500° and 0.46 at 550°; the effect of the NO tends to fade out after about 20% reaction. While the ratios are not a true measure of the max. inhibition, there is little doubt that the NO is more effective at the higher temp. This is believed to be the first case in which forward and reverse reactions have been shown to be equally subject to inhibition (cf. Stavely, *C. A.* **32**, 1170[1], for effect of NO on C_2H_6). C. J. West

Inhibition of ethylene polymerization by nitric oxide. H. D. Burnham and R. N. Pease. *J. Am. Chem. Soc.* **62**, 453(1940).—C_2H_4 (720 mm.) at 500° shows a time of 24 min. to 20% reaction; addn. of 20 mm. NO increases this to 73 min., the ratio of times being 0.33. The effect of the NO fades out as the reaction proceeds. The reaction is probably of the radical chain type. C. J. West

Preparation and structure of high-molecular-weight polybutenes. R. M. Thomas, W. J. Sparks, Per K. Frolich, M. Otto and M. Mueller-Cunradi. *J. Am. Chem. Soc.* **62**, 276–80(1940).—The polymerization of isobutylene (I) at low temps. with catalysts of acidic nature takes place with almost explosive violence and is among the most rapidly completed of org. reactions; under suitable conditions it is possible to obtain an almost quant. yield of rubber-like solid from liquid I within a fraction of a sec. A sample of I maintained at its b. p. and treated with a slow stream of BF_3 will show a considerable induction period, followed by a vigorous reaction to produce an oil, whereas a sunilar sample precooled to −80° will react immediately on introduction of the BF_3 to produce a polymer of much higher mol. wt. The presence of C_2H_4 and C_3H_6 in the I is apparently without effect; butenes are more reactive and cause a lowering in the mol. wt. of the polymer; 10% decreases the mol. wt. from about 250,000 to 75,000. Very small quantities of diisobutylene or triisobutylene greatly decrease both the yield and mol. wt. of the polymer; whereas dimers or trimers of I are capable of slow polymerization at room temp. to give oily products, high polymers have not been obtained by the use of the low-temp. technique. Other poisons are S compds. (H_2S or mercaptans) and H halides (HF, HCl); the latter have a marked depressing effect on the mol. wt. of the polymer in spite of their well-known promoter action in certain metallic halide-catalyzed alkylation or dimerization reactions. The poisoning effect of HCl may result from the formation of diisobutylene. The suitability of a catalyst for the low-temp. polymerization of I cannot be predicted. Temp. control is of great importance in the polymerization process since the reaction is rapid and exothermic; the heat of reaction is about 10,000 cals. per mole at about −78°; under 1 set of conditions the mol. wt. increases from 10,000 to about 200,000 on decreasing the temp. from −10 to about −100°. The mol. wt. of the product increases according to an exponential function with increasing proportion of diluent until a limiting concn. of approx. 80% by vol. is reached, at which point there occurs a precipitous drop in the mol. wt. The influence of catalyst concn. is discussed; the catalyst efficiency is highest at the greatest dilu. presumably because of a lower loss due to mech. occlusion of unreacted catalyst in the polymer. The polymerization of I to high-mol.-wt.-products can be carried out with yields of 90% or better. It is believed that the polymers are linear and probably have the head-to-tail structure. A polymer of about 20,000 mol. wt. on decompn. at 350° gave degradation products consisting of about 50% of monomol. and about 20% hydrocarbons boiling in the octene range. Heating 2,4,4-trimethyl-1-pentene at 350° for 1 hr. causes cracking and polymerization but no noticeable degree of isomerization. C. J. West



Solvolytic reactions of organic halides. Michael P. Balfe and Joseph Kenyon. *J. Am. Chem. Soc.* **62**, 445–6 (1940).—Comments are made on the mode of formulation of the solvated cation which is assumed as an intermediate by Winstein (*C. A.* **33**, 7181[3]). It is concluded that it is undesirable to assume that there is solvation of carbonium cations by covalency formation between solvent and cation in the hydrolysis of halides. C. J. West

Hydrogen fluoride as a condensing agent. IX. Reactions of di- and triisobutylene with phenol. J. H. Simons and S. Archer. *J. Am. Chem. Soc.* **62**, 451(1940); cf. *C. A.* **33**, 6814[1].—Addn. of 94 g. PhOH in 300 cc. CCl_4 to 121 g. HF in a Cu flask, followed by 1 mole of diisobutylene (added dropwise at 0°) gives 88 g. *tert*-BuC_6H_4OH; a mixt. of 20 g. 70% HF, 56 g. of olefin and 47 g. PhOH, kept at 0° for 48 hrs., gives 35 g. *p-tert*-octylphenol. Under the same conditions triisobutylene gave only *tert*-BuC_6H_4OH; dodecylphenol was not isolated, even with the 70% HF, although this might be accomplished by milder conditions. C. J. West

The preparation of trimethylene bromide. Yuoh-Fong Chi and Gia-Chien Liu. *J. Chem. Eng. China* **5**, 82 (1938).—Pure $Br(CH_2)_3Br$ is obtained by satg. 170.5 g. $CH_2{:}CHCH_2Br$ with dry HBr gas in the cold (cooling in a freezing mixt.), then closing the flask tightly with a rubber stopper and heating it at 35–40° for 4 hrs. It is purified by heating with 20 cc. abs. alc. and 3 g. Zn dust. The yield is 153 g. C. L. Tseng

Action of elementary fluorine upon organic compounds. VII. The vapor-phase fluorination of ethyl chloride. John D. Calfee, Nobukazu Fukuhara, DeWalt S. Young and Lucius A. Bigelow. *J. Am. Chem. Soc.* **62**, 267–9 (1940); cf. *C. A.* **34**, 977[5].—EtCl is fluorinated smoothly in a metal app. over Cu gauze, under conditions described in part VI; the Cu gauze was protected at all times from air and moisture, which decreased its efficiency greatly (not observed in reaction with C_2H_6). The fol-

lowing products were obtained on using gas vol. ratios of F:EtCl:N of 2:2:0, 3:2:0, 4:2:0 and 4:2:4; the yields are in liquid vol. % (rounded off to the nearest 5%): CF_4 10, 10, 10, trace; CF_3Cl (I) 5, 10, 15, trace; CF_3CCl_3F (II) trace, 5, 10, 5; $CF_2{:}CCl_2$ (III) 0, 5, 5, trace; EtCl 70, 40, 10, 20; residue, b. above 12° 5, 15, 20, 40; transition fractions, 15, 20, 30, 40. I–III have not been obtained before by the action of F on an org. compd. In addn. small amts. of CHF_2CHCl_2 (IV) and $MeCHCl_2$ (V) are also formed. The reactions involved in the action of F on EtCl appear to be:

A precise *anal. procedure for detg. F and Cl in stable org. gases* is described. C. J. West

Action of fluorine upon some simple aliphatic chlorinated hydrocarbons. Wm. T. Miller. *J. Am. Chem. Soc.* 62, 341-4(1940).—The phys. as well as chem. properties of F must be taken into account in considering actual reaction conditions. It has been found to be insol. in CCl_4 within the limit of measurement and, in general, a slight soly. for F in compds. of this type may be expected from its low b. p. Consequently, the reactions observed in this work occur principally in the gas phase and at the liquid surface under essentially "non-ionic" conditions, and radical-type mechanisms in which the F mol. is split sym. are considered to be of greatest importance. It is suggested that some of the observed differences of kind between the reaction of F with org. compds. and the reactions of the other halogens may be found in this direction. In addn. to the expected substitution products which were obtained from $CHCl_3$ and C_2HCl_5, C_2Cl_6 and C_4Cl_{10} were isolated in small amts. This converse of the Wurtz-Fittig type of reaction has also been observed to occur when CHF_3 reacts by sparking with F (Ruff and Bretschneider, *C. A.* 30, 2869[7]). $CHCl_3$ (150 g.), caused to react for 3 hrs. at 0°, gives 8.5 g. of $CFCl_3$ and some C_2Cl_6. C_2HCl_5 (350 g.), caused to react for 10 hrs. at 90 ± 3°, gives 297 g. of partially cryst. product; the following were isolated: 5 g. *sym*-$C_2Cl_4F_2$, 15.6 g. C_2Cl_4, 83.1 g. CCl_3F, 95.4 g. C_2HCl_5, 28.5 g. C_2Cl_6 and 0.1 g. *decachlorobutane*, m. 80 1°; in another expt. 365 g. C_2HCl_5 gave 343 g. crude material. $C_2H_2Cl_4$ (327 g.) at 50 ± 2° for 14 hrs. gave 310 g. of product which yielded a mixt. of C_2Cl_3H and *sym*-$C_2Cl_4F_2$ (which could not be sepd. by distn.), 67.8 g. of $Cl_2CHCFCl_2$, 11.2 g. C_2HCl_5 and about 168 g. of unreacted $C_2H_2Cl_4$. With olefins the dimerization observed by Bockemüller (*C. A.* 28, 118[4]) in the case of C_2Cl_4 was confirmed and also established for C_2Cl_3H; the products obtained may be termed *dimer addn. products;* it is assumed that in compds. of this type the F atoms are in the 1,4-positions. ClF was formed in the reaction mixts. and substitution and addn. products resulting from its action were isolated. ClF seems to add normally to ethylenic compds. without the formation of dimers since no monofluorobutane derivs. were found. C_2Cl_4 (335 g.) at 0° for 12 hrs. gives 354 g. of product; distn. gives 55 g. *sym*-$C_2Cl_4F_2$, 49.7 g. C_2Cl_6F and 66 g. of *difluorooctachlorobutane* (I), b_{20} 152.5°, m. 4·5°, n_D^{25} 1.5256, d_4^{20} 1.9272. C_2Cl_4 (65 g.) in 150 cc. $C_2Cl_3F_3$ with a slight excess of F at 0° gives (from 2 such reactions) 46.9 g. of $C_2Cl_4F_2$, 10.1 g. C_2Cl_5F, 49.5 g. I and a trace of C_2Cl_6. C_2Cl_3 (340 g.) for 10 hrs. at 0° gives 347 g. of product, yielding 14.9 g. of a mixt. of $CHClFCCl_3F$ and $CFCl{:}CCl_2$, 18.7 g. of a mixt. of $CHFClCCl_3$ and $CHCl_2CFCl_2$, 6 g. of *hexachlorobutene*, b_{25} 125.5°, m. 9.5–11°, n_D^{25} 1.5442, d_4^{20} 1.6880, and 1.2 g. of *octachlorobutane*, m. 75–6°. C_2Cl_3 in $C_2Cl_3F_3$ gives 14.6 g. of *difluorohexachlorobutane*, m. 55–6°. C. J. West

Substituted acetylenes and their derivatives. XXXVI. Halogenation in reactive solvents. 5. Chlorination of 1-hexyne in reactive solvents. 2. R. O. Norris and G. F. Hennion. *J. Am. Chem. Soc.* 62, 449–50(1940); cf. *C. A.* 33, 6235[7].—Yields are reported (in g.) for *cis*-BuCCl:CHCl, *trans*-BuCCl:CHCl, BuCCl:CCl_2, $BuCCl_2CHCl_2$ and $BuCCl_2CCl_3$ (values given in this order) for the chlorination of 1 mole of 1-hexyne (I) at 40–50° in the following solvents: 35% HCl in H_2O 23, 26, 25, 11, 14; 30% H_2SO_4 in H_2O 25, 25, 30, 8, 14; 30% H_3PO_4 in H_2O 24, 30, 36, 10, 17; 22% HCl in MeOH 45, 16, 65, 18, 6. The trichloride previously formulated as 1,2,2-trichlorohexane (II) is now found to be 1,1,2-trichloro-1-hexene; attempts to prep. II from I failed. Chlorination of 2-chloro-1-hexene in CCl_4 did not give II but *cis*-BuCCl:CHCl and $BuCCl_2CHCl_2$. C. J. West

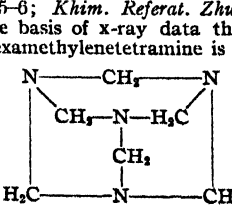
Allylic rearrangements. X. The reproducibility of the standard methods for the preparation of butenyl bromide mixtures. Wm. G. Young and Kenzie Nozaki. *J. Am. Chem. Soc.* 62, 311–13(1940); cf. *C. A.* 34, 370[2].—The standard methods developed by Y. and Lane (*C. A.* 32, 108[9]) for prepg. butenyl bromide (I) mixts. from butenols under controlled conditions have been tested with both crotyl alc. and methylvinylcarbinol; the compns. of the bromide mixts. are in good agreement with those previously reported. The thermal rearrangement of pure primary and secondary I in glacial AcOH satd. with HBr produces equil. mixts. which possess values of *n* qual. in agreement with the calcd. value of n_r (*C. A.* 32, 4518[8]). When attempts were made to rearrange the I at room temp. it was found that addn. of HBr occurred faster than rearrangement; at 15° in the presence of a trace of Bz_2O_2 it was possible to obtain a thermal equil. of the I before too large a quantity of dibromobutanes had been formed. C. J. West

Preparation of 1,3-diiodo-2-propanol. G. Lusignani. *Boll. chim. farm.* 78, 557–8(1939).—A mixt. of 1 kg. $HOCH_2CH(OH)CH_2OH$ and 20 g. AcOH at 100–10° is satd. with a stream of dry HCl to const. wt., cooled, neutralized with Na_2CO_3 and purified by distn. at reduced pressure, yielding the dichlorohydrin (I), b_{14} 68–75°. A mixt. of 500 g. I and 1.160 g. NaI moistened with H_2O is heated at 130–40° with frequent stirring for 2 hrs. The crude reddish brown product is washed with $Na_2S_2O_3$ and filtered, yielding 1,3-diiodo-2-propanol contg. 78% I, used in oil for external application in iodine therapy. C. R. Addinall

Macromolecular compounds. CCXXXI. Polyvinyl chlorides. H. Staudinger and J. Schneiders. *Ann.* 541, 151–95(1939); cf. *C. A.* 34, 1480[6].—Data are given for osmotic and viscosity measurements and cryoscopic behavior in various solvents of polyvinyl chlorides, chlorinated polyvinyl chlorides and of mixed polymers of vinyl chloride and vinyl acetate. C. J. West

Some relationships between polyvinyl acetate and polyvinyl alcohol. W. H. McDowell and W. O. Kenyon. *J. Am. Chem. Soc.* 62, 415–17(1940).—This study was made to det. whether polyvinyl acetates (I) could be transformed into polyvinyl alcs. (II) and whether the alcs. could be reacetylated to produce I which are similar to the original I. Because of the polymeric nature of the I and II, comparisons are made on the basis of the degree of polymerization (*P. D.*) as detd. by viscosity measurements. Four samples of I were prepd., using 2, 1, 0.75 and 0.3% of Bz_2O_2 by wt.; their sp. viscosities in Me_2CO were 0.050, 0.090, 0.115 and 0.209, corresponding to *P. D.* of 192, 346, 442 and 804. MeOH solns. of I (6 cc. per g. I) and 4% of the theoretical amt. of EtOH-KOH necessary to react with the Ac groups, on standing overnight, give II with η of 0.043, 0.056, 0.063 and 0.080, corresponding to *P. D.* of 165, 216, 242 and 308; reacetylation, by boiling 1 part II for 4 hrs. with 10 parts of a 2:1 (vol.) C_5H_5N-Ac_2O mixt., gives I with η 0.042, 0.056, 0.060, 0.080, corresponding to *P. D.* of 162, 216, 230 and 308. The repetition of the sapon. and reacetylation gave values for the *P. D.* very similar to the 1st series: I 1135, II 672, I 330, II 691, I 346, showing that the decrease in the *P. D.* occurred in the 1st cycle but not in the 2nd. Expts. with com. I (7 samples) yielded opposite results. The change in the *P. D.* occurred principally during reacetylation and the *P. D.* of the resulting I were about

0.5 those of the corresponding II. There appeared to be some decrease during deacetylation, especially with the I of higher viscosities, though the decrease was slight when compared with that which occurred during reacetylation. It is suggested that this decrease of the av. chain lengths may be due to rupture of unstable linkages present in the linear mol. C. J. West



Decomposition of alkyl peroxides: propyl peroxide, ethyl hydrogen peroxide and propyl hydrogen peroxide. E. J. Harris. *Proc. Roy. Soc.* (London) **A173**, 126–46 (1939); cf. Harris and Edgerton, *C. A.* **32**, 7805⁸.—To 120 cc. of 100 vol. % H_2O_2 at −20° was added 56 g. KOH in 60 cc. of H_2O, followed at 0° by 184 g. of Pr_2SO_4. The liquid was stirred 8 hrs. and sepd. The aq. layer was made just acid to methyl red. The upper layer was used in 5 or 6 repetitions of the expt. The combined lower layers were distd. to half vol. *in vacuo* and extd. exhaustively with ether after salting out with $(NH_4)_2SO_4$. The ether ext., dried over Na_2SO_4, concd. under diminished pressure and dried over $CuSO_4$, gave 1 g. of Pr_2O_2 (I), b_{20} 35°, $n_D^{19.5}$ 1.3911, n_D^{15} 1.3940, d_4^{20} 0.8254. An addnl. 0.5 g. was obtained by distg. the aq. layer *in vacuo*. By the technique of H. and E. in a study of the decompn. kinetics, the activation energy was detd. to be 36.5 kg.-cal./mol. The velocity consts. (k min.$^{-1}$) ranged from 0.015 at 146.5° to 0.246 at 175.4°. Since packed vessels gave the same result, the reaction is both homogeneous and unimol. Explosive decompn. began at 0.67 to 0.69 cm. at 199°, and 0.31 to 0.30 cm. at 210°. A blue flash was emitted at 0.007 cm. with 3.5 cm. air and at 0.01 cm. with 35 cm. of air at 271°; at 201°, 0.058 cm. with 11 cm. air, by the technique used by H. and E. The explosion of I therefore occurs at slightly lower pressures than that at Et_2O_2 (II). Decompn. of I at 180° gave a nearly equal wt. of liquid product, composed of EtCHO and CH_2O, together with a gaseous product composed of 5% CO_2, 42% CO, 6.1% H_2 and 36.5% mixed hydrocarbons. By explosion at 240°, 0.294 g. of I gave 0.199 g. or 36.7 cc. of 97% butane (3% CO) and 10.9 cc. of gas contg. 26.5% CO and 73.5% hydrocarbon C_nH_{2n+2}, n = 2.1. Hence the relative amts. of products are cstd.: 3.5×10^{-4} mols. of HCO_2H, 40 of CH_2O, 16 of C_4H_{10}, 1.8 of CO, 4 of EtOH, and 3.6 of C_2H_6. This reaction is therefore like the decompn. of II. An improved prepn. of EtO_2H (III) (cf. Baeyer and Villiger, *Ber.* **34**, 748(1901)) gave a product with d_4^{20} 0.9332, $n_D^{19.5}$ 1.3800, glassy at −100°. The analysis indicates 90% III and 10% MeCHO. The decompn. of III was studied at 100° (3–12 min.) and at 138° (1 min.). Since packing modified the rate, the reaction is heterogeneous (7 graphs). Luminous explosion proved possible between 195° at 8.9 mm. and 252.5° at 0.56 mm. For PrO_2H (IV) the explosion pressure at 233° was 1.5 mm., somewhat higher than for III at the same temp. These observations vary with the size of vessel; those above were made in a flask 4.2 cm. in diam.; no flash was seen in a 1.1-cm. vessel. Slow decompn. of III gave little gas, but explosion gave much. From 1 mol. of III at 170° and 320°, resp., the following no. of mols. of products were isolated: ?, 0.02 III; 0.0062, 0.033 CO_2; 0.0086, 0.364 CO; 0.0633, — O_2; 0.0298, 0.411 C_nH_{2n+2} (n = 1.18 and 1.32, resp.); — 0.03 H; 0.113, 0.115 CH_2O; 0.182, 0.195 AcH; 0.486, 0.125 EtOH. As an intermediate, EtO_2CH_2OH appears probable because its decompn. gave similar amts. of these products with the exception that the amt. of H was much larger. Study of the decompn. of IV between 180° and 300° with and without glass wool showed that the reaction is heterogeneous and that surface decompn. favors the formation of aldehyde and alc. The results were similar to those for III (table). Unchanged IV formed an *ester* with 3,5-$(NO_2)_2$-C_6H_3COCl, m. 62°. Heats of combustion detd. for III and IV were 5.4 and 6.3 kg.-cal./g. The relation of this work to a study of the combustion of hydrocarbons is discussed. New properties of IV (cf. Medvedeef and Alexeeva, *C. A.* **26**, 2412) (98.5% pure, 1.5% H_2O by analysis) are n_D^{15} 1.3890, d_4^{20} 0.9040, b_{20} 35°, b_{20} 38°, becoming glassy at −90°. 8 references. W. F. Bruce

The action of ethyl azide and phenyl azide on fuming sulfuric acid. K. W. Sherk, A. G. Houpt and A. W. Browne. *J. Am. Chem. Soc.* **62**, 329–31(1940).—The mechanism of the reaction between PhN_3 and fuming H_2SO_4 consists of the coördination of a H^+ ion to the α-N of the azide group resulting in the removal of 2 N atoms as N gas and permitting sulfonation to occur in the *m*-position. The unstable residue unites with a bisulfate ion to form *m*-sulfophenylaminomonopersulfuric acid which probably also exists in an isomeric form. The probable mechanism of the reaction between EtN_3 and fuming H_2SO_4 consists of the union of a H^+ ion with the EtN_3 and a subsequent loss of 2 N atoms which causes a shift of a H or a Me group from the α-C to the adjacent N. This gives products which, on hydrolysis, yield H_2SO_4 and a mixt. of AcH, HCHO, NH_3 and $MeNH_2$. No compds. contg. N linked to N were obtained as products of either reaction. A method for the sepn. of HCHO and AcH is described.

Unsaturated arsono carboxylic acids. H. J. Backer and R. P. van Oosten. *Rec. trav. chim.* **59**, 41–63(1940); cf. *C. A.* **30**, 7541¹.—A study of the prepn. and rates of reaction of the halogen-substituted acrylic, crotonic and isocrotonic acids with K arsenite. The dissocn. consts. $K_1 = 1.23 \times 10^{-3}$, $K_2 = 5.95 \times 10^{-5}$ and $K_3 = 2.49 \times 10^{-9}$ hold for α-arsonoacrylic acid (I); 4.37×10^{-4}, 2.42×10^{-5}, 1.77×10^{-9} for α-arsonocrotonic acid (II); and 2.58×10^{-3}, 9.42×10^{-6} and 1.56×10^{-9} for β-arsonocrotonic acid (III). III with HCl gives β-chloroisocrotonic acid. I is obtained from K arsenite on K 1,2-dibromopropionate or α-bromoacrylate. II (cis?) (trans?) is obtained similarly from α-bromocrotonic or α-bromoisocrotonic acid. III (cis?) (trans?) is obtained similarly from β-chlorocrotonic or β-chloroisocrotonic acid. The disappearance of cis-trans isomerism in the arsonic acids is not due to interconversion of the original crotonic acids before reaction with K arsenite. I m. 160° (decompn.). *Salts:* Pb (tertiary), insol. in hot water; Ba (tertiary + 12 H_2O); aniline (primary), decomp. 148°; strychnine (secondary + 6 H_2O), decomp. 155°. *Esters:* (a) spirocyclic with 2 mol. pinacol, m. 173–4° from acetone; (b) spirocyclic with 2 mols. cyclopentanonepinacol, m. 208–10° from acetone; (c) spirocyclic with 2 mols. pyrocatechol, m. 168–170° from $CHCl_3$ + petr. ether. I does not give the corresponding dichloroarsine with SO_2 + HCl but *trans*-β-chloroacrylic acid. II m. 158°–60° from alc. *Salts:* strychnine (secondary + 5 H_2O), decomp. 237°; quinine (secondary + 6 H_2O). III m. 151–2° from acetone + $CHCl_3$. *Salts:* Ba (tertiary + 8 H_2O), Ba (secondary + 3 H_2O); Ag (tertiary); aniline (primary) (IV), m. 140–1°. *Esters* of III: (a) 2 mols. pinacol, spirocyclic, m. 198–200° from $CHCl_3$; (b) 2 mols. cyclopentanonepinacol (+ 2 $CHCl_3$), m. 162–2.5° from $CHCl_3$; (c) 2 mols. cyclohexanonepinacol (+ 1 Me_2CO) (V), m. 233–4° (decompn.), from acetone; (d) 2 mols. pyrocatechol, spirocyclic, m. 175–6° from $CHCl_3$ + petr. ether; (e) 1 mol. tartaric acid, cyclic, decomp. 240° from acetone + $CHCl_3$. The dichloroarsine from III, by SO_2 + HCl, m. 88.5–9.5° from 20% HCl. H_2O_2 on the dichloride regenerates III. β-Arsenodicrotonic acid, from III with H_2SO_4 + Na hypophosphite, decomp. 193°. Crystallographic data are given for I, III, IV and V. G. Powell

Structure of urotropine. A. F. Oskerko. *Farm. Zhur.* 1938, No. 3, 35–6; *Khim. Referat. Zhur.* **2**, No. 5, 46 (1939).—On the basis of x-ray data the following ring structure for hexamethylenetetramine is most probable:

W. R. Henn

Methods of preparation and uses of butyraldehyde. S. M. Slavina. *Org. Chem. Ind.* (U. S. S. R.) **6**, 521–5 (1939).—A discussion of the literature and patents with 80 references. Chas. Blanc

Stable and labile semicarbazones from methyl amyl ketone. W. S. Rapson and R. G. Shuttleworth. *J. Chem. Soc.* 1940, 99.—AcAm yields a *semicarbazone*, m. 96–7°, which changes on standing overnight to 121–3°; the change occurs in the dark or in cold EtOH soln. Later it was impossible to obtain this labile form. The stable form could not be converted into the labile form by exposure of the EtOH soln. to ultraviolet light. AcBu gives a semicarbazone, m. 123.5–4.5°, which may not be identical with that of Michael (*C. A.* **13**, 1855), who gives the m. p. as 118°. C. J. West

Production of acetone by catalytic dehydrogenation of isopropyl alcohol. M. Ya. Kagan, D. I. Kodner and G. D. Lyubarskiĭ. *Org. Chem. Ind.* (U. S. S. R.) **6**, 494–7 (1939).—Tentative results showed that in the dehydrogenation of 2-propanol at 300–400° in the presence of ZnO the side reaction of dehydration to olefins can be considerably retarded by the addn. of MgO, Na_2CO_3 and water glass to the catalyst. Contrary to Sabatier and Senderens (*Ann. chim.* [8], **4**, 467(1905)), pure Cu catalyst gives up to 2% C_3H_6. The addn. of water glass to Cu inhibits the dehydration reaction but gives some mesityl oxide. Better results are obtained with Cu treated with Na_2CO_3. A yield of 92.6% Me_2CO and pure H was obtained at 260° in the 1st run in the presence of the skeleton catalyst, the nature which is not given. 30 references. Chas. Blanc

Tertiary oxonium salts. II. Hans Meerwein, Ernst Battenberg, Heinrich Gold, Emanuel Pfeil and Georg Willfang. *J. prakt. Chem.* **154**, 83–156(1939); cf. *C. A.* **31**, 1760⁹.—Addn. of 14 g. of $ClCH_2\underset{\frown}{CH}.O.CH_2$ (I) to 19 g. $BF_3.Et_2O$ in 50 cc. ether at a rate such that the ether constantly boils, followed by stirring for 2 hrs., gives 100% of $(Et_2O).BF_4$ (II), m. 92°; similarly 6.4 g. $BF_3.Pr_2O$ in 40 cc. Pr_2O, treated with 4.6 g. I, gives 30% of *tripropyloxonium borofluoride*, m. 73–4° (decompn.). $SbCl_5$ (75 g.), added to 100 cc. Me_2O with cooling in Et_2O-CO_2, followed by slow addn. of 11.6 g. I, gives 95.5% of *trimethyloxonium hexachloroantimoniate* (III), $(Me_2O).SbCl_6$, m. 158° (decompn.), which is stable for months in a closed vessel. Evapn. of the mother liquor from III gives 48.1 g. of a brown oil; to show that this contains $ClCH_2(MeOCH_2)CHOSbCl_4$ (IV), it was decompd. with Rochelle salt and KOH (the soln. being kept neutral to litmus), giving 8.7 g. of *γ-chloropropylene glycol Me ether* (V), b. 170–4°; $SbCl_5$ and Et_2O, followed by I, give 95% of the *Et analog* (VI) of III, m. 135–7° (decompn.); it is considerably more sol. than III in org. solvents; heating causes decompn. with formation of EtCl; 109 g. of VI with 30% aq. alkali gives 16.9 g. Et_2O, 6.5 g. EtOH and 3.6 g. EtCl; the filtrate from VI gives the *Et analog* of IV, red-brown, m. 91°; aq. alkali give 82.5% of the Et analog of V, b. 178–84°. $SbCl_5$, Et_2O and $(C_2H_4)_2O$ give 79% of $(Et_2O).SbCl_5$, m. 132°; the mother liquor yields $EtOCH_2CH_2OSbCl_4$. $AlCl_3$, Et_2O and I give 82% of *triethyloxonium tetrachloroaluminate*, $(Et_2O).AlCl_4$, m. 72° (decompn.); the ether filtrate contains 86.4% of the *Al chloroalcoholate* of γ-chloropropenyl glycol Et ether, m. 114–15°; 5 g. of the salt gives 2.6 g. of $ClCH_2CH(OH)CH_2OEt$, b_{12} 71–3°; heating the salt gives EtCl and $AlCl_3.Et_2O$; decompn. of 19 g. of the salt with 2 *N* NaOH gives 0.5 g. EtOH, EtCl and Et_2O; with H_2O alone 16 g. of the salt gives 4 g. EtCl and 3.5 g. Et_2O. $FeCl_3.Et_2O$ and I give 100% of *trimethyloxonium tetrachloroferriate*, $(Et_2O).FeCl_4$, m. 74° (decompn.); the filtrate gives 89% of the *ferric chloroalcoholate* of $ClCH_2CH(OH)CH_2OEt$, yellow, m. 103–5°; decompn. with H_2O gives 82% of EtOH. $BF_3.Me_2O$ (1.7 moles) and 1 mole MeF, allowed to stand 3 months in a sealed tube, give 38% of $(Me_2O).BF_4$, m. 148° (decompn.) (previously reported 124.5°); careful heating gives the 2 components. $BF_3.Et_2O$ and MeF, after standing 4 months, give 52% of *methyldiethyloxonium borofluoride*, m. 99–100° (decompn.). $BF_3.Me_2O$ and PrF give $(Me_2O).BF_4$ and not the expected $(PrMe_2O).BF_4$. $SbCl_5.Et_2O$ (1 mole) and 7 moles EtCl, allowed to stand 14 days at room temp., give a small yield of VI. Neg. results were obtained in attempting to add MeCl or EtCl to the etherates of $AlCl_3$, $FeCl_3$, BCl_3 or $SnCl_4$; $SbCl_5.Et_2O$ does not add $ClCH_2OMe$, $PhCH_2Cl$ or AcCl; $ClCH_2OMe$ is decompd. into HCHO and MeCl; $PhCH_2Cl$ gives a resin with loss of HCl; AcCl is transformed into AcOEt and EtCl. If the reaction of $SbCl_5.Et_2O$ and I, including the filtration and washing, is carried out at the temp. of Et_2O-CO_2, there results 98.5% of the internal *salt* $ClCH_2CH(CH_2OEt)\overset{+}{O}\overset{-}{SbCl_5}$ (VII), decomps. 58°; it is not pptd. by ether from solns. in org. solvents; decompn. with alk. Rochelle salt soln. gives 90% of EtOH and 96.3% of the Et analog of V, b_{15} 74.5–5.5°; the latter on shaking with 0.1*N* NaOH loses HCl and yields glycide ether; decompn. of VII with H_2O also did not yield EtCl. Slowly heating VII to 90° gives 85% of EtCl and the Et analog of IV. Similarly $SbCl_5.Et_2O$ and $(C_2H_4)_2O$ give 97.5% of the *salt* $Et_2O\overset{+}{C}H_2CH_2O\overset{-}{SbCl_5}$ (VIII), decomps. 58°. On standing at room temp. VII and VIII decomp. into EtCl and the $SbCl_4$ compds.; in 20 hrs. the m. p. of VIII decreases from 58 to 23°; VII shows the same change in 10 hrs.; after 18 hrs. VII loses 16.2% EtCl, whereas VIII gives 6.5% EtCl in 24 hrs.; after 70 hrs. the reaction is practically complete in each case. VII and $SbCl_5.Et_2O$ in Et_2O at room temp. give 100% of VI and 97.5% of the Et analog of IV; VIII gives 100% of VI and 87% of the *$SbCl_4$ compd.* of $HOCH_2CH_2OEt$, m. 107°. $BF_3.Me_2O$ in Me_2O, cooled with Et_2O-CO_2 and treated with I, gives 81.3% of the *salt* $ClCH_2CH(CH_2OMe_2)\overset{+}{O}\overset{-}{BF_3}$, with 1 mol. Me_2O, m. 75–80° (decompn.); it is very unstable and decomps. in 2-3 hrs. to a yellow-brown oil with liberation of BF_3. $BF_3.Et_2O$ reacts similarly but on warming to room temp. the ppt. from 57.7 g. $BF_3.Et_2O$ and 44.4 g. of I reacts with the Et_2O which adheres to it to give 7.1 g. EtF, 7 g. Et_2O, 31.5 g. $BF_3.Et_2O$, 26.5 g. $ClCH_2CH(OEt)CH_2OEt$ (b_{14} 72–3°, d_4^{23} 1.017), 1.2 g. of $ClCH_2CH(OBF_2)CH_2OEt$, b_{14} 80–90° and 4.9 g. $[ClCH_2CH(CH_2OEt)O]_3B$ (**IX**?), $b_{0.05}$ 145–50°. If the inner oxonium salt from 50 g. $BF_3.Et_2O$ and 35 g. I is treated with $BF_3.Et_2O$ at the temp. of Et_2O-CO_2 there results 61 g. (91%) of II and 40.2 g. of **IX**. It is probable that $SnCl_4.Et_2O$ forms an inner oxonium salt with I but it is so unstable that it cannot be isolated; on standing for some time the soln. contg. 26.1 g. of $SnCl_4$ gives 8.6–9.6 g. of the *$SnCl_4$ compd.* (**X**) of $(ClCH_2)_2CHOH$ (**XI**), which may be isolated by extg. the $SnCl_4.Et_2O$ with CCl_4 and may be crystd. from $C_6H_4Cl_2$; on decompn. with Rochelle salt and $NaHCO_3$ 61 g. **X** gives 14.4 g. **XI**. $BF_3.C_5H_5N$ (**XII**) and $(C_2H_4)_2O$ in C_5H_5N with ice cooling give 100% of the *salt* $C_5H_5N\overset{+}{O}CH_2CH_2O\overset{-}{BF_3}$ (**XIII**), m. 131–2°; it is hydrolyzed by H_2O; with aq. $NaI.HgI_2$ **XIII** gives yellow needles, m. 39°, of the *salt* $(HOCH_2CH_2NC_5H_5)HgI_2$ and with $NaCl.HgCl_2$ $(HOCH_2CH_2NC_5H_5)Cl.6HgCl_2$. **XII** and I in C_5H_5N give 62.8% of the *salt* $ClCH_2CH(O\overset{-}{BF_3})CH_2\overset{+}{N}C_5H_5$, which, recrystd. from SO_2 by addn. of $PhNO_2$, m. 164–5°. $BF_3.NMe_3$ and $(C_2H_4)_2O$, heated and shaken in a sealed tube at 40–5° for 2 hrs. and at 60–70° for 2 hrs., give 100% of the *salt* $Me_3\overset{+}{N}CH_2CH_2O\overset{-}{BF_3}$, m. 296–8° after pptn. from $MeNO_2$ by $PhNO_2$. $BeCl_2$ (8 g.) in 80 cc. ether forms an oil which reacts with 9.3 g. I to give 97.5% of the *Be chloroalcoholate* of $(ClCH_2)_2CHOH$, with 1 mole Et_2O, m. 114–15°. $BeCl_2.Et_2O$ and $(C_2H_4)_2O$ give 96% of the *Be chloroalcoholate* of $ClCH_2CH_2OH$, with 1 mole of Et_2O, m. 199–200°. $BiCl_3$ and I in ether or C_6H_6 give 100% of the *compd.* $(ClCH_2)_2CHOBiCl_2$, m. 145–50°. Cryst. compds. were not obtained from I and the etherates of $ZnCl_2$, $SbCl_3$, BCl_3, $TiCl_4$ and $AlBr_3$. That $(Et_2O).BF_4$, $(Me_2O).BF_4$, $(Et_2O).SbCl_6$ and $(Et_2S)BF_4$ are salts is shown by their elec. cond. in SO_2 (data given for various dilns.). The equiv. cond. of $(Et_2O)OH$ at 20° is 187, 192 and 197 for *v* 10, 100 and 400. $(Et_2O).BF_4$ (9.5 g.) and 5.8 g. Me_2O in 30 cc. CH_2Cl_2, on standing 5 days, give 92% of $(Me_2O).BF_4$. VI (5.4 g.) and $(CH_2)_4O$ (1.5 cc.) give 6.2 g. of *ethylidenetetramethyleneoxonium hexachloroantimoniate*, $[Et.O(CH_2)_4]$.-

$SbCl_5$ (XIV), m. 132° (decompn.); decompn. of 46 g. of the salt with 200 cc. 2 *N* NaOH with stirring for 5 hrs. gives 0.8 g. of $(CH_2)_4O$ and EtOH, 2.8 g. of $EtO(CH_2)_4OH$, $b_{19.5}$ 87°, d_4^{19} 0.9073 and 3.2 g. of the *ether* $EtO(CH_2)_4O(CH_2)_4OEt$, $b_{18.5}$ 140°. VI and $(CH_2CHMe)_2O$ at room temp. for a few hrs. give the *α,α-di-Me deriv.* of XIV, m. 142° (decompn.). IV and $(CH_2)_5O$ give 52% of *ethylpentamethyleneoxonium borofluoride*, very hygroscopic, m. 45°. VI and $(CH_2)_5O$ in 2 hrs. give 92% of *ethylpentamethyleneoxonium hexachloroantimoniate*, m. 154–5° (decompn.); dioxane gives the *compd.* $[O(CH_2CH_2)_2O.Et].SbCl_5$, m. 156° (decompn.). Solid $(Me_3O).BF_4$ added to 10% of H_2AuCl_5 gives *trimethyloxonium chloroaurate*, $(Me_3O).AuCl_4$, yellow, m. 133° (decompn.); *Et analog*, yellow, m. 92° (decompn.); *ethylpentamethylene analog*, yellow powder. *Triethyloxonium chloroplatinate*, decomps. above 120°; it is stable only for a short time. II and a soln. of 1 cc. $SbCl_5$ in 50 cc. of a satd. NaCl soln. give $(Et_3O)SbCl_6$; $SnCl_4$ in NaCl give *triethyloxonium hexachlorostannate*, needles, which slowly decomp. at room temp. into $SnCl_4.Et_2O$ and EtCl; at 45° the decompn. is complete in 5 min. II and BiI_3.NaI in ice-cold H_2O give the *compd.* $(Et_3O).Bi_2I_7$, dark red, which slowly decomps. with liberation of EtI; working at low temps. a salt with the composition $(Et_3O)BiI_4$, brick-red, can be obtained which in the dry state splits off EtI and Et_2O, giving $(Et_3O).Bi_2I_7$; $BiCl_3$ in concd. NaCl gives the *compd.* $(Et_3O).Bi_2Cl_7$, m. 84° (decompn.). II and NaI.HgI_2 give the *compd.* $(Et_3O).HgI_3$, yellow, which is completely decompd. in 24 hrs. at room temp. and much more quickly at 50 60°; this compd. ppts. from 2 l. of a soln. contg. 0.1 g. II. $HgCl_2$ in NaCl gives the very unstable *salt*, $(Et_3O).HgCl_3$. II and an acidified soln. of $Na_4Fe(CN)_6$ give the pale yellow-green *salt* $(Et_3O)_2.H_2Fe(CN)_6.2H_2O$, which is stable for only a short time. Et_2SO (8.3 g.) and 13.5 g. II give *diethyloxyethylsulfonium borofluoride*, $(Et_2SOEt).BF_4$, which decomps. quickly in the air; VI gives the very unstable $(Et_2SOEt).SbCl_6$, m. 159° (decompn.); it begins to decomp. within 1 hr. Me_3NO and II in CH_2Cl_2 give $(Me_3NOEt).BF_4$, which is very hygroscopic; VI gives $(Me_3NOEt).SbCl_6$. II and $CO(NH_2)_2$, mixed in the dry state, soon liquefy, forming $[(H_2N)_2COEt]BF_4$, which forms a *picrate*, m. 184–5° (decompn.); alkali decomps. the salt, giving *O*-ethylisourea. II and $AcNH_2$ give the *compd.* $[MeC(:NH)OEt]BF_4$, very hygroscopic. $(Et_3O).AlCl_4$ and PhCN, on standing 14 days, give *Ph-CN.AlCl*$_3$, m. 96–8°, and PhCCl NEt, identified as PhCONHEt, m. 70 1°. Similar results were obtained with *p*-$MeOC_6H_4CN$, $PhCH_2CONH_2$ and PhCH.CH-$CONH_2$. C. J. West

Formic acid as a solvent for ozonization investigations. Rodger M. Dorland and Harold Hibbert. *Can. J. Research* **18, B**, 30–4 (1940).—Because of the insoly. of birch formic acid lignin in the usual ozonization solvents (anhyd. EtOAc or $CHCl_3$) 95% HCO_2H (I) was tried as solvent for the ozonolysis of maleic acid (II), vanillin (III) and veratraldehyde (IV) as test substances for the new solvent. The ozonizations were conducted at 0°, the solvent removed under reduced pressure, the residue dissolved in water, made up to a definite vol. and aliquots used for the estn. of the reaction products. Ozonization of II in EtOAc gave 15% glyoxylic acid and 80% oxalic acid; in I the product was 98% glyoxylic acid. Ozonization of III in EtOAc gave 21% vanillic acid; in I 45% of unchanged III was recovered. Ozonolysis of IV in EtOAc gave 45% veratric acid; in I, 62% unchanged IV was recovered. It thus appears that I protects the aldehyde group during ozonolysis and that the degradation of the aromatic nucleus is diminished by the presence of this solvent. It is proposed that the protection of the aldehyde group may be due to the reaction of H_2O_2 (formed during decompn. of the ozonide) with I. W. Gordon Rose

Gradual decomposition by oxidation of fatty acids into their next lower homologs. H. Mendel and J. Coops. *Rec. trav. chim.* **58**, 1133–43 (1939) (in English).—The method involved the following steps: bromination in the α-position, conversion to the α-HO acid (formation of the Me ester, reaction with AcOK in AcOH and hydrolysis), oxidation to the aldehyde with $Pb(OAc)_4$ and immediate oxidation of the aldehyde with air and excess of $Pb(OAc)_4$; the total yield of the next lower acid was approx. 84%. Br (225.3 g.) was slowly added to a mixt. of 100 g. palmitic acid and 12.1 g. red P at 80° during 10 hrs.; MeOH (77.8 g.) was added with stirring during 3 hrs. (15° for the 1st, 40° for the 2nd and 80° for the 3rd hr.), giving 136.6 g. of Me ester; this was heated with 136 g. AcOK in 272 g. AcOH (prepd. by heating the soln. of AcOK in 99.6% AcOH until the b. p. was 118°) for 8 hrs. at 160°; the acetate was then heated with 270 g. MeOH contg. 2.5% HCl for 20 hrs. and the Me ester sapond. with MeOH-KOH, giving α-hydroxypalmitic acid (I). A soln. of 14 g. $Pb(OAc)_4$ in 250 cc. C_6H_6, stirred while a vigorous stream of air is being passed through it, is treated with 25 g. I during 8 hrs. (0.2 g. every 4 min.); at the end of each hr. 10 g. $Pb(OAc)_4$ is added; after an addnl. 4 hrs., the excess $Pb(OAc)_4$ is destroyed with $C_2H_4(OH)_2$; evapn. of the C_6H_6 and purification through the K salt give 20.45 g. $C_{14}H_{29}CO_2H$. The details are also given for the similar reactions starting with stearic acid. C. J. West

Comparative investigations of the hydrotropic activity of corresponding and isomeric members of the C_7 and C_8 series. Carl Neuberg and Hans Armin Fischer. *Rec. trav. chim.* **59**, 77–86 (1940) (in German).—Hydrotropy is the capacity of aq. salt solns. to dissolve compds. insol. in H_2O. Alkali salts of the acids of the C_7 and C_8 series possess this property and comparative expts. are reported for the Na salts of $C_6H_{11}CO_2H$ (I), BzOH (II), hexahydrobenzoic acid (III) and methylcyclopentanecarboxylic acid (IV). The soly. capacity of I is in general greater than that of the cyclic compds.; of these the true hydroaromatic members (III and especially IV) are more reactive than the pure aromatic compd. (II). Obvious differences are also to be observed between $C_7H_{15}CO_2H$, $PhCH_2CO_2H$ and *o*-, *m*- and *p*-$MeC_6H_4CO_2H$. Hydrotropy has also been observed with the isomeric Na salts of *p*-$MeC_6H_4SO_3H$ and $PhCH_2SO_3H$. Many of the observations support the view that addn. occurs with the formation of unstable derivs. of ortho acids, as $RC(OH)_3$ or $RSO(OH)_3$. Data are given for $PhNO_2$, $PhNH_2$, AcOEt, AmOH, $PhCH_2OH$ and lecithin. C. J. West

Remarks on "A new method for the cleavage of unsaturated aliphatic acids." Donald Price and Richard Griffith. *J. Am. Chem. Soc.* **62**, 450–1 (1940).—It is pointed out that the paper by Hsing and Chang (*C. A.* **34**, 983[4]) has been anticipated by Nunn and Smedley-MacLean (*C. A.* **30**, 3406[3]) and others. C. J. West

Addition of hydrogen bromide to non-terminal double bonds. The isopropylidene group. Crotonic acid. D. C. Grimshaw, J. B. Guy and J. C. Smith. *J. Chem. Soc.* **1940**, 68–71.—The effect of O or of peroxides in reversing the normal addn. of HBr, well established in the case of terminal double bonds ($CH_2.CHCH_2 + HBr + O \rightarrow CH_2BrCH_2CH_2$—), has been detected also in olefins with sufficiently polar non-terminal double bonds ($Me_2{:}CH$— + HBr + O → $Me_2CHCHBr$—); but where there is conjugation with a CO group as in crotonic acid (I), no reversal is observed, I in C_6H_6 (with Bz_2O_2, BzO_3H or ascaridole) and HBr, with or without O, give only β-bromobutyric acid. 13-Ketotetradecanoic acid (II) (m. 75°) gives an *Et ester*, $b_{0.5}$ 153°, m. 36°; reaction with MeMgI gives a mixt. of II and *13-methyl-13-hydroxytetradecanoic acid* (sepd. by removal of II as the semicarbazone), m. 61°; the overall yield is poor. Dimethylheptadecylcarbinol (III) (m. 45.5°) with $(CO_2H)_2$ at 180–200° for 1 hr. gives 80% of 2-methyl-2-nonadecene (IV), b_{25} 212–15°, m. 12.5°; O_3 gives margaric acid. III and HBr at 120° for 4 hrs. or PBr_3 at 20–30° give *2-bromo-2-methylnonadecane* (V), m. 19.5°. IV by normal addn. of HBr gives V; in the presence of peroxides addn. of HBr yields the *1-Br isomer* (VI) of V, f. p. 14°, m. p. 14.1° and 16.5°. Et heptadecylmalonate and Na in PhMe, heated 1 hr. at 90° and then refluxed 1 day with MeI, give *Et methylheptadecylmalonate*, $b_{0.5}$ 195–7°, m. 11° (transparent) and 25° (opaque); the free *acid* m. 100–1°; heating at 180–210° *in vacuo* for 1 hr. gives *2-methylnonadecanoic acid*, m. 57.5° (capillary), 56.4° (thermometer in liquid) (the yield is

79% on the $C_{17}H_{33}I$ used); the *Et ester* ($b_{0.12}$ 170°) on reduction gives 75% of *2-methylnonadecan-1-ol*, $b_{0.2}$ 167°, m. 39–40°; HBr at 130–40° gives VI. The m.-p. curve of IV and VI is given. C. J. West

Long-chain acids. I. Extension of the isoprene rule. P. C. Mitter and Phanindra Nath Bagchi. *J. Indian Chem. Soc.* **16**, 402–4 (1939).—By assuming that larger mols. can be formed from isoprene by head-to-tail union followed by addn. of H_2O at a conjugated double bond at 1 end of a chain, partial or complete hydrogenation and removal of side-chain Me groups by oxidation, and partial or complete oxidation of the terminal groups, the formation of a large no. of long-chain aliphatic mono- and dibasic acids can be explained. The close connection of farnesol with sabininic acid suggests that juniperic acid and thapsic acid are similarly related to a diterpene, $C_{20}H_{32}$. Incomplete hydrogenation of the unsatd. system of the intermediate alc. and suitable oxidation would lead to ambrettolic acid and epiambrettolic acid (closely related to aleuritic acid, present in shellac resin). C. R. Addinall

The constitution of the linoleic acid of seed fats. T. P. Hilditch and H. Jasperson. *J. Soc. Chem. Ind.* **58**, 233–41 (1939).—Study of the linoleic acid from cottonseed oil supports the view that natural and regenerated α-linoleic acids are identical, probably *cis*-Δ^9-*cis*-Δ^{12}-octadecadienoic acid, while β-linoleic acid is believed to be a mixt. of approx. equal parts of α- and *cis*-Δ^9-*trans*-Δ^{12}- acids. With 0.3% Se at 220° for 3 hrs. in a current of CO_2 α- and β-linoleic acids are isomerized, and upon alk. $KMnO_4$ oxidation yield 2 tetrahydroxystearic acids, m. 144° and 135°, identical with those produced from natural linoleic acid by AcO_2H or HOCl followed by alkali. H. and J. believe that these tetra-HO acids are derived from *trans*-Δ^9-*trans*-Δ^{12}- acid which may have been formed during the isomerization. The yields of cryst. tetrabromostearic acid, m. 114°, from each of the linoleic acids were: natural, 50.3% theory; regenerated α-, 45.4%; regenerated β-, 21.4–25.8%; isomerized α-, 2%; isomerized β-, nil. R. E. Reeves

Polyethenoid acids of the C_{18} series in butterfat. T. P. Hilditch and H. Jasperson. *J. Soc. Chem. Ind.* **58**, 241–3 (1939).—The structures of the octadecadienoic acids from butterfat remain unknown. From 1.5 kg. of fat 72 g. unsatd. C_{18} acids, I no. 115.0, was obtained; 8.9 g. gave no cryst. tetrabromostearic acid. Oxidation with alk. $KMnO_4$ under controlled conditions gave only a trace of tetrahydroxystearic acid. Low maleic anhydride addn. values (2.1, 2.6) indicate little conjugated unsatn. After isomerization with Se (cf. preceding abstr.) and sepn. of the solid (elaidic) acids the remaining liquid acids, I no. 115.6, gave no cryst. tetrahydroxystearic acid on alk. $KMnO_4$ oxidation. R. E. Reeves

The fatty oil of the seeds of Ongokea klaineana Pierre. A. Castille. *Ann.* **543**, 104–10 (1939).—The oil of the seed of *Ongokea klaineana* Pierre, extd. with Me_2CO and Et_2O, is a thick yellow liquid, d_4^{20} 0.9826, n_D^{25} 1.5079, sapon. no. 191.4, Ac no. 67, Wijs no. 148, SCN no. 64, acid no. 3.8, unsaponifiable 3.27%. The satd. fatty acids of the oil consist of caproic, caprylic, lauric, palmitic, stearic and arachidic acids. The ether-sol. Pb salts yield *erythrogenic acid* (I), $C_{18}H_{26}O_2$, m. 39.5°, d^{45} 0.9309, d^{60} 0.91966, n_D^{60} 1.49148; the absorption spectrum of I shows 5 characteristic max., at 2275, 2400, 2666, 2530, 2824 A., ε 1167, 870, 870, 700 and 700; the Raman spectrum of the Et ester shows characteristic lines at ω 281, 462, 676, 1252, 1390, 1608, 1730, 2261 and 2914. The irradiated Li salt is rose, the Ca salt is orange-yellow and the Ba salt purple. Catalytic reduction of I yields stearic acid and shows the presence of 5 double bonds. O_3 gives 1 mol. each of HCHO, $(CO_2H)_2$, adipic acid (II) and Et azelate. Irradiation gives an isomeric red compd. Oxidation of the Na salt with $KMnO_4$ gives a *dihydroxy acid* (*cyanogenic acid*) (III) m. 92°; irradiation gives a blue compd., isomeric with III. I may be $CH_3{:}CHC{:}C(CH_2)_4C{:}C(CH_2)_7CO_2H$ or $CH_2{:}CH(CH_2)_4C{:}CC{:}C(CH_2)_7CO_2H$. The unsaponifiable portion contains an alc., m. 328° (insol. in Me_2CO; acetate, m. 192.5°), phytosterol, stigmasterol and an unstable oil, b_{760} 209°, d^{20} 0.8438, n_D^{20} 1.49999; catalytic reduction gives decane (absorption of 5 mols. of H_2). Nessler reagent gives the *Hg deriv.*, $(C_{10}H_{11})_2Hg$. The oil in $CHCl_3$ shows max. in the absorption spectrum at 2980, 2813, 2644, 2536, 2507, 2473, 2336 and 2231 A.: the ω-values of the Raman spectrum are at 470, 480, 1629, 1638, 2033, 2135, 2169, 2197, 2262, 2292. With O_3 the oil yields HCHO, HCO_2H, $(CO_2H)_2$ and II. HNO_3 oxidation gives almost entirely II. The oil must therefore be $HC{:}C(CH_2)_4C{:}CCH{:}CH_2$ or $HC{:}CC{:}C(CH_2)_4CH{:}CH_2$. It appears to be a degradation product of I but the method of its formation is not clear. C. J. West

Physical properties of the aliphatic acid anhydrides. David T. Lewis. *J. Chem. Soc.* **1940**, 32–6.—The anhydrides were fractionated through a glass-bead column, then twice over the fused Na salt of the fatty acid and twice through a similar column under reduced pressure; the higher anhydrides slowly decomp. on distn. at atm. pressure, becoming light brown. The following b. ps. of the anhydrides are cor.: acetic (I), b_{770} 139.4–9.5°; propionic (II), $b_{771.9}$ 168.1–8.4°, b_{16} 66–7°; butyric (III), $b_{770.4}$ 198.1–9.7°, b_{18} 85–6°; hexanoic (IV), b_{766} 246–8°, b_{18} 143–4°. Values are given for d_4, γ and *P* for I and II at 5° intervals from 15 to 50° and for III and IV from 20 to 50°; I, d_4^{20} 1.0810, γ 32.56, *P* 225.6 (mean *P* 225.9, calcd. 225.0); II, d_4^{20} 1.0110, γ 30.30, *P* 301.8 (mean *P* 302.2, calcd. 303); III, d_4^{20} 0.96677, γ 28.93, *P* 379.2 (mean *P* 379.7, calcd. 381.0); IV, d_4^{20} 0.92016, γ 28.26, *P* 536.8 (mean *P* 537.6, calcd. 537.0). Values are also given for the viscosities at 5° intervals from 20 to 50°; they increase regularly as the series is ascended. The values from the equation $\log P^{2/3}\eta = (785 \log M)/T - 5.951$, where *P* is the parachor and *M* is the mol. wt., agree well except for I, the anomaly in this case undoubtedly being due to the singular properties of the Me group. The higher anhydrides were analyzed by refluxing 1 g. with excess of NaOH and titrating with acid. The values of *P* reveal that the anhydrides exhibit a typical ester anomaly, the other parts of the mols. making a normal vol. contribution. C. J. West

Reaction of ethers with chromous halides. Fr. Hein and H. Kraft. *J. prakt. Chem.* **154**, 285–308 (1940); cf. *C. A.* **24**, 4256.—$CrCl_2$ or $CrBr_2$ in dioxane (I), allowed to react at room temp. in N, gives an olive-green or reddish brown soln.; after filtration of the excess of Cr salt (absence of air and moisture in an app. which is illustrated), dry NH_3 is passed into the filtrate, the unstable complex is filtered, washed with ether and dried over H_2SO_4 for at least 1 week. The principal *product* is $[(NH_3)_3CrCl_2O{-}CH_2CH_2CrCl_2(NH_3)_3].^1/_3$ I; other *compds.* analyzed are $[(NH_3)_3CrCl_2OCH_2CH_2OCrCl_2(NH_3)_3]$ + 0.23$[Cr(O{-}CH_2CH_2O)_3Cr.0.5Et_2O$ and $[(NH_3)_3CrCl_2OCH_2CH_2OCr{-}Cl_2(NH_3)_3]$ + 0.27$[Cr(OCH_2CH_2O)_3Cr].Et_2O$; conditions for the prepn. of these compds. are not clearly stated. With $CrBr_2$ the following *compds.* were analyzed: $[(NH_3)_3{-}CrBr_2OCH_2CH_2OCrBr_2(NH_3)_3].NH_3.4/3Et_2O$, $[(NH_3)_3Cr{-}Br_2OCH_2CH_2OCrBr_2(NH_3)_3].NH_3.I$, and $[(NH_3)_3CrBr_2{-}OCH_2CH_2OCrBr_2(NH_3)_3].0.5Et_2O$ + 0.29$[Cr(OCH_2CH_2{-}O)_3Cr].0.5Et_2O$. These compds. are decompd. by MeOH, giving $Cr(OMe)_3$. That $C_2H_4(OH)_2$ is formed in these reactions is proved by its isolation from the NH_3 complex after heating with H_2O on the water bath. The filtered soln. from I and $CrBr_2$, treated with *p*-$C_6H_4(NH_2)_2$ (II) in ether, gives a light olive-green ppt., somewhat sol. in the I-Et_2O mixt., 2 analyses of which gave $[II.CrBr_2OCH_2{-}CH_2OCrBr_2.II].1.5Et_2O$ + 0.53 $[II.Cr(OCH_2CH_2O)_3Cr.{-}II].1.5Et_2O$ and $[II.CrBr_2OCH_2CH_2OCrBr_2.II].0.25Et_2O$ + 0.9$[II.Cr(OCH_2CH_2O)_3Cr.II].0.25Et_2O$. $PhCH_2OEt$ and $CrBr_2$ react to give principally the lilac-colored $[Br_2CrOEt(NH_3)_3].0.5Et_2O$ (or $0.25Et_2O$); in some instances there was formed a *complex* $[Br_2CrOEt(NH_3)_3].{-}NH_3$ + 0.25$[Cr(OEt)_3]0.5Et_2O$; with $CrCl_3$ there resulted only the *complexes* $[Cl_2CrOEt(NH_3)_3].0.25Et_2O$ + 0.15$[Cr(OEt)_3].0.25Et_2O$ or $[Cl_2CrOEt(NH_3)_3]$ + 0.29-$[Cr(OEt)_3]0.5Et_2O$. Reaction with Me_2O at a low temp. gives the *complexes* $[Cl_2CrOMe(NH_3)_3]0.33Me_2O$ and $[Br_2CrOMe(NH_3)_3]$ (also with $0.25Me_2O$). Various prop-

erties and reactions of these complexes are discussed. C. J. West

Aliphatic polyamines. IX. J. van Alphen. *Rec. trav. chim.* **58**, 1105–8(1939) (in English); cf. *C. A.* **33**, 6242[6].—$Br(CH_2)_4Br$ (74 g.) in 150 cc. EtOH, slowly added to 125 cc. $C_2H_4(NH_2)_2.H_2O$, refluxed 1 hr., excess solid KOH added and the heating continued for 1 hr., gives *1-(2'-aminoethyl)pyrrolidine* (I), $(CH_2CH_2)_2NCH_2CH_2NH_2$, b. 166–7°, strongly basic liquid with a fishy smell (*picrate*, yellow, decomps. 219°). I and PhNCO in Et_2O give *1-[2'-(2''-phenylureido)ethyl]pyrrolidine*, an oil, analyzed as the *picrate*, yellow, m. 193°; the *2''-phenylthioureido deriv.* m. 95°. I and BzH give the *benzylideneamino deriv.*, yellow oil, b_{17} 176°, which is reduced by Na in EtOH to the *2'-benzylamino deriv.*, pale yellow, b_{20} 172° (*picrate*, yellow, m. about 147°); PhNCO gives *1-[2'-(3''-phenyl-1''-benzylthioureido)ethyl]pyrrolidine*, m. 133°. **X.** *Ibid.* **59**, 31–40(1940) (in English).—$(CH_2)_6Br_2$ (10 g.) in 250 cc. abs. EtOH and 100 cc. $C_2H_4(NH_2)_2.H_2O$, boiled 1 hr., 150 g. solid KOH added, the mixt. refluxed for some time, the KBr filtered, the filtrate distd. until the temp. is 105°, 50 g. KOH added and after boiling a few min. allowed to stand overnight, give 2 layers, distn. of the upper layer of which gives 3 fractions, b_{25} below 150° (I), 150–250° (II) and 250–350° (III). Redistn. of II gives 25 g. (?) of *1,6-bis(2'-aminoethylamino)hexane* (IV), b_{16} 212°, with an amine-like odor; it gives a violet-blue biuret reaction; *picrate*, IV.$4C_6H_2(NO_2)_3OH$, m. 213°; *nitrate*, IV.$4HNO_3.H_2O$. IV and PhNCO in Et_2O give *1,6-bis(3'-phenyl 1'-(2''-(3'''-phenylureido) ethyl) ureido)-hexane*, m. 216°; the *3'''-phenylthioureido analog*, prepd. in EtOH, m. 125–35°, was not obtained pure; it appears to sep. with 2 mols. of EtOH; prepd. in Et_2O it m. 90–110°. IV and CS_2 give a light yellow thiocarbamate which, heated at 140°, gives *1,6-bis(2'-thioletrahydro-1'-imidazolyl)-hexane*, yellow, m. 216°. The *benzyl deriv.* of IV, isolated as the *HCl salt*, decomps. 255°; the free amine and BzH in Et_2O give *1,6-bis(2'-phenyl-3'-benzyletrahydro-1'-imidazolyl)hexane*, m. 128°. III contains *1,22-diamino-3,10,13,20-tetraazadocosane*, $[CH_2NH(CH_2)_6NH(CH_2)_2NH_2]_2$, yellow liquid, b_{23} 314–23°, m. 32°, faint tobacco-like odor; it does not yield a solid picrate; PhNCS gives *1,22 - bis(2' - phenylthioureido) - 3,10,13,20 - tetraphenylthiocarbamido-3,10,13,20-tetraazadocosane*, m. 90 120°; the corresponding *phenylureido deriv.* m. 100–20°. The prepn. of these compds. proves that the hexamine is a straight-chain compd., otherwise 6 PhNCS groups could not be added. I contains a very small quantity of *1-(2'-aminoethyl)-1-azacycloheptane* (V), b. 212°, which results in somewhat larger yield from 43 g. $(CH_2)_6Br_2$ and 21 cc. $C_2H_4(NH_2)_2.H_2O$ in 1 l. EtOH on standing 3 months; the filtrate from the $C_2H_4(NH_2)_2.2HBr$ is evapd. to about 50 cc., excess solid KOH is added, the mixt. heated 0.25 hr., filtered and further evapd. until 2 layers appeared. *Picrate* of V, yellow, m. 200°. The *2''-phenylthioureido deriv.* m. 93°; the *2''-phenylureido deriv.* did not cryst. but was isolated as the yellow *picrate*, m. 183°. A survey is given of the reactions between an excess of $C_2H_4(NH_2)_2$ and various α,ω-dibromo paraffins. C. J. West

Preparation, properties and thiocyanogen absorption of triolein and trilinolein. D. H. Wheeler, R. W. Riemenschneider and Chas. E. Sando. *J. Biol. Chem.* **132**, 687–99(1940); cf. *C. A.* **33**, 2484[9]; **34**, 278[9].—The triglycerides of oleic and linoleic acids were prepd. by direct esterification with glycerol in a N atm. with *p*-$MeC_6H_4SO_3H$ as catalyst. Both compds. exhibit polymorphism, the 3 forms of triolein melting at 4.7–5.0°, −12° and −32° and the 2 forms of trilinolein at −13.1 to −12.8°. A 4-hr. reaction time is most suitable for thiocyanogen absorption by these glycerides. A no. of Br addn. products are formed by the bromination of trilinolein. A 9.1% yield of cryst. bromides was obtained which is about ¾ of the 12.5% theoretical yield of tetrabromostearic acid. *Triolein*, n_D^{25} 1.4621, n_D^{40} 1.4586, d_{40} 0.8988, free oleic acid 0.05%. *Trilinolein*, n_D^{25} 1.4719, n_D^{40} 1.4683, d_{40} 0.9184, free linoleic acid 0.03%. A. P. Lothrop

The increase of rotation of *d*-lactic acid. Sinogu Hukuda. *J. Biochem.* (Japan) **30**, 473–7(1939)(in German); cf. *C. A.* **33**, 1362[1].—The addn. of a 5% H_3BO_4 soln. to a lactic acid soln. increases [α] from 2.14° to 5.12° with increasing acid concn. The most marked increase was obtained with the addn. of NH_4 molybdate, the greatest change taking place (about a 50-fold increase) when the mixt. contains 5 mols. lactic acid to 1 mol. molybdate. S. Morgulis

Occurrence of an isomer of ricinoleic acid in the fatty oil from the seeds of Vernonia anthelmintica. N. L. Vidyarthi and M. Venkatesh Mallya. *J. Indian Chem. Soc.* **16**, 479–80(1939).—The fatty oil from *V. anthelmintica* (*C. A.* **7**, 2775) has $[\alpha]_D^{25}$ −10.7°; Ac value, 135.1. The mixed fat acids of the oil have $[\alpha]_D^{25}$ −7.2°, Ac value, 118.2, and contain about 60% of a *HO acid* (I), $C_{18}H_{34}O_3$, sapon. equiv. 299.0 (calcd., 298.2), $[\alpha]_D^{25}$ −7.8°, 1 value, 108.4 (I value of Ac deriv., 73.8 (calcd. for $C_{20}H_{36}O_4$, 74.4)). I differs from quince oil acid in that it does not form a dibromide. It is isomeric with ricinoleic acid but contains a OH group in a different position. C. R. Addinall

Preparation of butyl acetoricinoleate. B. N. Rutovskiĭ and L. E. Ostroumova. *Org. Chem. Ind.* (U. S. S. R.) **6**, 238–40(1939).—Bu acetoricinoleate (I) was prepd. in good yields (1) by alcoholysis of castor oil and acetylation of the resulting Bu ricinoleate (II) and (2) by interaction of BuOAc and the oil with the H_2SO_4 catalyst. (1) Castor oil and excess of BuOH is refluxed until the alcoholysis is completed and the reaction mixt. is treated with excess of 98.76% AcOH and 1% H_3PO_4 at 135° for 4 hrs. The presence of BuOH retards the hydrolysis of II to BuOAc. The reaction mixt. is neutralized with 5% alc. NaOH and distd. with steam or *in vacuo* to free it from volatile matter, giving 64.7% I (82.4% based on castor oil). (2) A mixt. of 100 g. castor oil, 149.2 g. BuOAc and 1% H_2SO_4 (based on the wt. of oil) is refluxed 6 hrs. at 113–18°, yielding 60.5% I (77.3% based on oil). Redistn. of I at a pressure above 10 mm. results in a higher acid value and a lower ester value. I, b_{18} 240 5°, b_{25} 249–58°, has an acid no. 34.7 and ester no. 211.7. Chas. Blanc

The chemical constitution of agar-agar. E. G. V. Percival. *Pharm. J.* **142**, 189(1939).—A review of recent work, with 12 references; cf. *C. A.* **32**, 1214, 8372[3], 8374[5]. S. Waldbott

Constitution of arabic acid. III. Isolation of methyl heptamethylaldobionate from methylated degraded arabic acid. J. Jackson and F. Smith. *J. Chem. Soc.* **1940**, 74–8; cf. *C. A.* **34**, 989[6].—The Ba salt of degraded arabic acid yields a Me ester (I) of a methylated degraded arabic acid, $[\alpha]_D^{18}$ −56° ($CHCl_3$, *c* 1.3), $\eta_{sp.}^{20}$ 0.035 in *m*-cresol. On hydrolysis with 14 *N* H_2SO_4 the rotation changes from −14° to 103° in 112 hrs. Hydrolysis of 10.4 g. I with 100 cc. 14 *N* H_2SO_4 at room temp. for 51 hrs., dilu. to 500 cc. with ice-water and neutralization with $BaCO_3$ give 7.1 g. of a mixt. of methylated sugar and the Ba salts of methylated uronic acids, which readily reduces Fehling soln. Addn. of dry Et_2O to this mixt. in 15 cc. MeOH gives 3.45 g. fraction I (II), 0.445 g. of fraction II (III) and from the mother liquors 0.608 g. fraction III (IV); the residue (2.44 g.) consists of methylated sugars. Fractions II–IV were combined and freed of Ba with *N* H_2SO_4, giving 2.43 g. of a sirup; this was fractionated from EtOH by addn. of petr. ether. The fractions contg. the hexamethylaldobionic acid were dissolved in 1% MeOH-HCl and kept at room temp. for 140 hrs.; removal of the HCl with Ag_2CO_3 and distn. give the Me ester of 2,3,4-trimethylmethylglucuronoside (V), $b_{0.03}$ 120° (bath temp.), n_D^{15} 1.4490, $[\alpha]_D^{15}$ 80° (H_2O, *c* 1.2), and the Me ester of hexamethyl-6-β-glucuronosidomethylgalactoside (VI), $b_{0.03}$ 220°, n_D^{15} 1.4685–90, $[\alpha]_D^{15}$ 42° (H_2O, *c* 1.7). Hydrolysis of VI by refluxing in 3% MeOH-HCl for 8 hrs., removal of the HCl with Ag_2CO, and heating the sirup with 0.3 *N* $Ba(OH)_2$ for 2 hrs. at 60°, give 2,3,4-trimethylmethylgalactoside (VII) and the Ba salt of 2,3,4-trimethylmethylglucuronoside; the VII was characterized by its transformation to the anilide of 2,3,4-trimethylgalactose, m. 166°. V was identified as the amide of 2,3,4-trimethyl-α-methylglucuronoside, m. 183°.

The Me ester of hexamethyl-6-β-glucuronosido-β-methyl-galactoside, m. 94°, $[\alpha]_D^{25}$ −21° (H_2O, *c* 1.6), yields an *amide*, m. 196°, $[\alpha]_D^{25}$ −18° (H_2O, *c* 3.7). These facts indicate that the side chains in degraded arabic acid do not consist of a single unit of glucuronic acid but rather that each side chain is composed of a terminal or "end" glucuronic acid group, which is linked through at least 1 galactose residue with the main galactose chain. IV. The formation of 3-galactosidogalactose by hydrolysis of degraded arabic acid. *Ibid.* 79–82.—Degraded arabic acid (100 g.) in 750 cc. H_2O was heated on the boiling water bath for 95 hrs., giving 75 g. of the Ba salts of the uronic acids and 28 g. of a mixt. of reducing sugars. Methylation of 15 g. of the sugar mixt. with Me_2SO_4 and 30% aq. NaOH and then with Purdie's reagents gives 5.5 g. of 2,3,4,6-tetramethylmethylgalactoside (I) and 0.67 g. of *octamethyl-3-galactosidogalactose* (II), $b_{0.08}$ 215–30° (bath temp.), n_D^{25} 1.4660, $[\alpha]_D^{25}$ about 0.5° (H_2O, *c* 2.2). Hydrolysis of II with 4% MeOH-HCl (boiling 8 hrs.) gives I and 2,4,6-trimethylmethylgalactoside (III). Hydrolysis of I with *N* H_2SO_4 gives 2,3,4,6-tetramethylgalactose, whose anilide m. 192°; III gives 2,4,6-trimethylgalactose, whose anilide m. 178°. Thus the identification of these derivs. of galactose shows that both the 1,6- and the 1,3-type of linkage are present in degraded arabic acid. Some of the galactose units are mutually joined by 1,6-links and the formation of II by prolonged autohydrolysis of the acid has now proved that some of the galactose units are also joined by 1,3-units. A tentative structure is suggested for degraded arabic acid. C. J. West

dl-Threonic acid from 3-hydroxycrotonic acid. J. W. E. Glattfeld and E. C. Lee. *J. Am. Chem. Soc.* 62, 354–6(1940).—Acrolein (I) has been transformed in 5 steps into *dl*-threonic acid (II) with an over-all yield of 4.1% of the theory. HCN is added to I and converted to Et vinylglycolate (III) in 61% yield; PBr_3 and C_5H_5N at 20°, treated dropwise with III in C_5H_5N, give 51% of Et 3-bromocrotonate; stirring the ester with aq. K_2CO_3 for 4 hrs. gives 27.8% of 3-hydroxycrotonic acid (8.6% from I); oxidation with $AgClO_3$ and OsO_4 gives 48% of II. Details are given for carrying out each step. C. J. W.

1,4-Dibromo-1,4-dipivalylbutane. Reynold C. Fuson and John W. Robinson, Jr. *J. Am. Chem. Soc.* 62, 358–60(1940).—$(CH_2CH_2COCl)_2$ (0.136 mole) and 0.30 mole of Me_3CMgCl in ether, on decompn. with NH_4Cl at 0°, washing the ether soln. with Na_2CO_3 and crystn. from low-boiling petr. ether, give about 25% of *1,4-dipivalylbutane* (I), m. 52–2.5°; *di-2,4-dinitrophenylhydrazone*, m. 251–2°. Distn. of the filtrate from the crystn. of I gives 5 g. of impure *2,2,9,9-tetramethyl-3,8-decanediol* (II), $b_{3.5}$ 119–24°. The Na_2CO_3 washing liquor yields 5 g. of *δ-pivalylvaleric acid*, b_2 151–3°, m. 45–7°. Oxidation of II with CrO_3 gives only a small yield of I. I in CCl_4 gives 90% of the *1,4-di-Br deriv.* (III), m. 119.5–20°; cleavage by the action of 5% NaOH upon the C_5H_5N salt of III gives I. Refluxing 4 g. III and 20 g. Et_2NH in C_6H_6 for 14 hrs. gives 21% of *1,4-dipivalyl-1,3-butadiene* (IV), m. 145–6°; *di-2,4-dinitrophenylhydrazone*, m. 280–2°. Reduction of IV with $NaHSO_3$ gives a compd. m. 70–2°; Raney Ni and H give I. IV does not condense with maleic anhydride but reacts with PhMgBr to give 1,4-dipivalyl-2,3-diphenylbutane. III and NaCN in EtOH-AcOEt, refluxed 40 hrs., give *1,4-dicyano-1,4-dipivalylbutane* (V), m. 92–3°, and a neutral oil (VI) (cyanocyclobutane deriv. or a dihydro-1,4-pyran deriv.), b_6 163–8°, n_D^{25} 1.4722; VI forms a *2,4-dinitrophenylhydrazone*, $C_{21}H_{27}N_5O_5$, m. 225–7°; 2 *oximes* were prepd., m. 183–5° (with AcOK) or 146–8° (with NaOH). Heating V with concd. HCl for 2 hrs. at 140–50° gives a *compd.* $C_{16}H_{26}Cl_2N_2O_2$, m. 198–200°; this may be $[CH_2C(CONH_2):CCl\text{-}CMe_2]_2$. V gives 2 moles of gas in the Grignard reagent but attempts to alkylate it and to effect ring closure through the di-Na deriv. were fruitless. C. J. W.

A form of urinary glucuronic acid. M. Rangier and P. M. de Traverse. *Bull. soc. chim. biol.* 21, 1327–9 (1939).—Glucuronic acid is a constituent of urochrome. Cf. *C. A.* 33, 5846⁴. L. E. Gilson

Introduction of substituted vinyl groups. IV. Primary 1-alkenylalkylmalonic esters. Arthur C. Cope, Walter H. Hartung, Evelyn M. Hancock and Frank S. Crossley. *J. Am. Chem. Soc.* 62, 314–16(1940); cf. *C. A.* 33, 1273⁸.—Alkylidenemalonic esters may be transformed into Na derivs. by the use of EtONa in EtOH at −5° or with powd. Na in Et_2O or C_6H_6; in the latter case some of the ester is reduced. The use of $NaNH_2$ in liquid NH_3 or in inert solvents is inadvisable, since partial decompn. occurs during the reaction and subsequent alkylation gives rather impure products in poor yield. The alkyl halide is added in 1 portion and the soln. immediately heated to the b. p. The synthesis of vinyl esters is not very satisfactory, all of the $MeCH{:}C(CO_2Et)_2$ being transformed into a high-boiling polymer. The yield depends upon the size of the alkylidene group and reaches a max. of 86–93% with the isopentylidene esters; the alkylations occur more rapidly with the higher members of the series and there is less opportunity for their destruction by alcoholysis. Yields were higher in 2 cases when the reaction was carried out in iso-PrOH, showing that alcoholysis is an important factor influencing the yields in this system. *Di-Et alkylpropenylmalonates: Pr*, b_{20} 138–40°, n_D^{25} 1.4371, d_{25}^{25} 0.9774, 51% on 4 hrs.' refluxing (other values of *n* and d. as for this ester); *iso-Pr*, b_{19} 135–5.5°, *n* 1.4404, d. 0.9842, 35% in 4.5 hrs.; *Bu*, b_{20} 148–51°, *n* 1.4390, d. 0.9687, 50% in 5.5 hrs. *Di-Et alkyl-1-butenylmalonates: Et*, b_{18} 134–5°, *n* 1.4367, d. 0.9745, 75% in 5 hrs.; *Pr*, b_{19} 142–5°, *n* 1.4375, d. 0.9637, 55% in 5 hrs.; *iso-Pr*, b_{19} 141–3°, *n* 1.4400, d. 0.9710, 67% in 6 hrs.; *allyl*, b_{17} 144–5°, *n* 1.4470, d. 0.9776, 79% in 1 hr.; *Bu*, b_{19} 152–6°, *n* 1.4390, d. 0.9561, 59% in 5 hrs.; *sec-Bu*, b_{28} 159–60°, *n* 1.4425, d. 0.9689, 21% in 7 hrs. *Di-Et isobutenylethylmalonate*, b_{24} 140–1°, *n* 1.4395, d. 0.9837, 40% in 0.5 hr. *Di-Et alkyl-1-pentenylmalonates: Et*, b_{27} 154–7°, *n* 1.4374, d. 0.9656, 60% in 3.5 hrs.; *Pr*, b_{26} 161–3°, *n* 1.4381, d. 0.9551, 65% in 3 hrs.; *iso-Pr*, b_{28} 160–3°, *n* 1.4410, d. 0.9627, 70% in 3.5 hrs.; *di-Et alkyl-1-isopentenylmalonates: Me*, b_9 119–22°, *n* 1.4348, d. 0.9647, 93% in 0.1 hr.; *Et*, b_{19} 141–2°, *n* 1.4350, d. 0.9568, 88% in 0.3 hr.; *Pr*, b_{26} 154–6°, *n* 1.4349, d. 0.9487, 86% in 1 hr.; *iso-Pr*, b_{26} 152–3.5°, *n* 1.4372, d. 0.9545, 86% in 0.5 hr. *Di-Et alkyl-1-hexenylmalonates: Me*, b_{27} 164–6°, *n* 1.4407, d. 0.9647, 82% in 0.8 hr.; *Et*, b_{28} 168–9.5°, *n* 1.4410, d. 0.9612, 58% in 3 hrs. V. A rearrangement involving the migration of an allyl group in a three-carbon system. Arthur C. Cope and Elizabeth M. Hardy. *Ibid.* 441–4.—EtMeC:C(CN)CO_2Et and $CH_2{:}CHCH_2Br$ with EtONa give 34% of *Et (1-methylpropenyl)allylcyanoacetate* (I), b_1 94.5–6°, n_D^{25} 1.4609, d_{25}^{25} 0.9735; $CH_2{:}CHCH_2Cl$ gives 17% of I. Distn. of I at 15–20 mm. causes partial rearrangement; repeated refluxing at 18–60 mm. gives *Et (1,2-dimethyl-4-pentenylidene)cyanoacetate* (II), $CH_2{:}CHCH_2CHMeCMe{:}C(CN)\text{-}CO_2Et$, b_{16} 147–8°, n_D^{25} 1.4780, d_{25}^{25} 0.9816; rearrangement is practically complete after refluxing 4 hrs. at 18 mm. (150–60°) or after 20 min. at atm. pressure (260°). $MeCH{:}CMeCR(CN)CO_2Et$, in which R is Me, Pr or Bu, is completely stable at much higher temps. than are required to rearrange I; consequently a cyclic mechanism is regarded as probable. This appears to be the 1st case in which an allyl group has been observed to undergo a thermally induced α,γ-shift in a 3-C system; it appears probable that this rearrangement occurs for reasons similar to those responsible for the Claisen rearrangement of enol, phenol and vinyl ethers and that the 2 types of rearrangement follow similar mechanisms. Catalytic reduction of I gives *Et sec-butylpropylcyanoacetate* (III), b_{11} 122.5–3.5°, n_D^{25} 1.4356, d_{25}^{25} 0.9378. Reduction of Et (1-methylpropylidene)cyanoacetate gives 74% of Et (*sec*-butyl)-cyanoacetate, b_{11} 105–6°, n_D^{25} 1.4273, d_{25}^{25}, 0.9617; reaction with PrBr and EtONa gives 73% of III. III and $CO(NH_2)_2$ with EtONa give 10% of 5-propyl-5-*sec*-butylbarbituric acid, m. 135–7°. Catalytic reduction of 5.8 g. of II yields 3 g. of *Et 1,2-dimethylpentylcyanoacetate*, b_{12} 134–6°, n_D^{25} 1.4389; *5-(1,2-dimethylpentyl)barbituric acid*, m. 219.5–20.5°. Shaking 7 g. II with 50 cc. concd. NH_4OH for 30 hrs. gives 54% of $NCCH_2CONH_2$ and 60% of $CH_2{:}CHCH_2CHMeAc$ (IV), b. 137–8°, n_D^{25} 1.4215;

semicarbazone, m. 84.5°; *2,4-dinitrophenylhydrazone*, m. 41–2°. The structure of II also follows from its synthesis in 29% yield by refluxing 9.3 g. of IV, 9.5 g. $NCCH_2$-CO_2Et, 0.89 g. $AcONH_4$, 1.2 g. AcOH and 25 cc. C_6H_6 for 1 hr. C. J. West

Action of nitrosyl chloride on monobromomalonamides. M. P. Shah and V. B. Thosar. *J. Indian Chem. Soc.* **16**, 556(1939).—Treatment of $H_2C(CONHR)_2$ with NOCl (I) gives $HON{:}C(CONHR)_2$ and it was expected that I would react with $HCBr(CONHR)_2$ to yield the corresponding nitroso compds., $NOCBr(CONHR)_2$. A suspension of 5 g. of $HCBr(CONHC_6H_4Me)_2$ in 150 cc. benzene was satd. with dry gaseous I at 0° and, after 1 hr., the mixt. was refluxed until the condensed vapor was colorless. The reaction mixt. was filtered hot and concd. The product was washed with petr. ether and, on recrystn. from alc., yielded *bromochloromalonodi-p-toluide*, $ClBrC(CO$-$NHC_6H_4Me)_2$, m. 135°. Similarly, chlorination of $HCBr$-$(CONHCH_2Ph)_2$ gave the corresponding *chlorobromo compd.*, $C_{17}H_{16}BrClN_2O_2$, m. 153°. The same compds. are obtained by the action of SO_2Cl_2. C. R. A.

Condensation and reduction experiments with acetonedicarboxylic acid. Gust. Komppa. *Ann. Acad. Sci. Fennicae* **A51**, No. 3, 15 pp.(1938)(in German).—On sapon. of 14.7 g. of $OC(CH_2CH_2CO_2Et)_2$ (I), prepd. in 80% yield by a modification of the procedure of Marckwald (*Ber.* **20**, 2813(1887)), by passage of HCl into the mixt. with 10 g. H_2O for 1 hr., $OC(CH_2CH_2CO_2H)_2$ (II), m. 141.5°, was obtained in 83% yield. From the distillate obtained by dry distn. of 100 g. of the Pb salt of II there was prepd. 0.68 g. of the disemicarbazone (III) of 1,4-cyclohexanedione (IV); when prepd. directly from IV, III m. 231°. Dry distn. of the Ca, Ba, Sn, Mn or Th salt of II gave no IV. II gives with AcCl or Ac_2O a dilactone, m. 63° (Vollhard, *Ann.* **253**, 221(1889)), which was different from IV, as shown by a mixed m. p. detn. H_2SO_4 treatment of the product formed by condensation of I by means of NaOEt or powd. Na gave no IV as expected from the literature. The semicarbazone of I, fine needles, m. 89°, when treated with Na, first in ether, then, after removal of the ether by distn., at 130° for 3 hrs., gave no IV. Ten g. of $OC(CH_2CH_2CO_2Me)_2$ (V) in 30 cc. $CHCl_3$ was treated in sunlight with 4 cc. of a mixt. of 1 part Br in 2 parts $CHCl_3$; after the Br was decolorized, a further 14 cc. of the Br soln. was added, resulting in a 75% yield (after vacuum distn., addn. of MeOH and powerful cooling) of the di-Br deriv. (VI), m. 50°. VI heated with an equal wt. of quinoline at 50–60° gave 75% of $OC(CH{:}CHCO_2$-$Me)_2$ (VII), m. 177°. VII hydrolyzed by 75% H_2SO_4 or HCl (passage into a hot HOAc soln. of VII) gave OC-$(CH{:}CHCO_2H)_2$ (VIII), m. 230°. Dry distn. of the Ba or Th salt of VIII, or treatment of the Na salt of VIII with Ac_2O on the water bath, gave no *p*-quinone. Treatment of the semicarbazone of II with NaOEt in EtOH (1) in a sealed tube for 15 hrs. at 170–180° or (2) by refluxing in an oil bath for 8 hrs. gave impure II and no pimelic acid. Likewise, the hydrazone of II treated with NaOEt (in an oil bath) gave no pimelic acid. Passage of HCl for 24 hrs. into 3 g. of II in 30 g. HOAc in the presence of Zn-Hg gave only unchanged II. Passage of HCl for 19 hrs. into 4.3 g. of V in 50 g. abs. MeOH in the presence of 23 g. Zn-Hg gave only V and II. V treated with H under 3 atm. pressure in the presence of Pt or Pt-Pd catalysts gave only II; I passed with H over clay impregnated with Ni gave either unchanged I or low-mol. wt.-decompn. products, depending upon the velocity. II (8 g.) was treated with 200 cc. H_2O, the calcd. amt. of Na_2CO_3 and 517 g. of 3.3% Na-Hg (in small portions) and allowed to stand 1.5 days; the mixt. was acidified and extd. with Et_2O, neutralized with soda soln., evapd. to dryness and extd. repeatedly with alc. and Et_2O. After removal of the solvent, the oil was distd. *in vacuo*, giving 69% γ-hydroxypimelic lactone, b_{10} 230–1°, m. 81.5° (after crystn. from C_6H_6). $HOCH(CH_2CH_2CO_2Ag)_2$ was prepd. and analyzed. George Ayers

The nitrogenous constituents of jack bean. D. Ackermann and W. Appel. *Z. physiol. Chem.* **262**, 103–10 (1939).—The ext. of defatted jack-bean meal made with hot 50% EtOH contains canavanine, arginine, desaminocanavanine, choline, trigonelline, betonicine and two new bases, *canoine*, $C_{12}H_{24}O_3N_2$ (I), m. 188–9°, and *kilogine*, $C_7H_7O_3N$ (II), m. 240–2°. I is pptd. by phosphotungstic acid and by $CuCO_3$, is sol. in H_2O to the extent of 0.6% at 18.5°, is optically inactive, gives a ninhydrin test and is pptd. by $Hg(NO_3)_2$, aq. $HgCl_2$, $HgSO_4$, picric acid (picrate m. 120–1°) and picrolonic acid. It does not react with $KMnO_4$ in the cold. Tests with $Me_2NC_6H_4CHO$, Hopkins-Cole reagent, Millon reagent and the xanthoproteic reaction are neg. One N reacts with HNO_2 according to Van Slyke. *N*-Me is absent. *Desaminocanavanine* forms a *seminitrate*, m. 215.5°. Water dissolves 0.55% of II at 20.5°, giving an acid soln. which is optically inactive. The ninhydrin, Jaffé and pyridine tests are neg. as are the Millon and xanthoproteic reactions. No N is given by HNO_2. II gives a monohydrate. It is thought that II may be *o*-$HONHC_6H_4CO_2H$. It gives a red color with $FeCl_3$. Milton Levy

New chemical proof of the cyclic structure of glucosaminides. Albert Neuberger. *J. Chem. Soc.* **1940**, 29–32.—*N*-Acetyl-α-methylglucosaminide (I) and Me_2SO_4 in 40% NaOH (mixed during 6 hrs., 30° for the 1st hr. and 50° thereafter) give 70% of the 3,4,6-tri-Me deriv., m. 151°, $[\alpha]_D$ 151° (H_2O) (cf. Cutler, Haworth and Peat, *C. A.* **32**, 1661[1]); refluxing with 3.5 *N* HCl for 2 hrs. gives 70% of 3,4,6-trimethylglucosamine-HCl (II), m. 215° (decompn.), the structure of which as a 3,4,6-tri-Me compd. has been established by synthesis (Haworth, Lake and Peat, *C. A.* **33**, 3337[2]), whence it follows that I also must be a pyranoside. Since α- and β-Me glucosaminide-HCl can be converted into the corresponding *N*-Ac compds. under conditions which exclude change of the ring structure (N. and Pitt Rivers, *C. A.* **33**, 2491[2]), the 4 known Me glucosaminides all possess pyranoside structures. II, BzCl and $NaHCO_3$ give 75% of *N-benzoyl-3,4,6-trimethylglucosamine*, m. 213°, $[\alpha]_D$ 124° (initial), 105° (after 48 hrs.) in wet C_6H_6N; it is unchanged after standing 6 days in 1:1 dioxane-H_2O contg. excess Br or on treatment with $KMnO_4$ in Me_2CO. II (2.5 g.) in 50 ml. H_2O contg. 0.75 g. $NaHCO_3$, treated with 2 equivs. $1\text{-}C_{10}H_7SO_2NNaCl$ in 250 ml. H_2O (added in 20 portions during 5 hrs.), gives *2,3,5-trimethyl-d-arabofuranose*, $b_{0.01}$ 80–3° (bath temp.), $[\alpha]_D$ 38° (MeOH), characterized by oxidation to the lactone, m. 33°. If 3 equivs. of oxidizing agent are added at once and the reaction is carried out at pH 5, the product consists mainly of 2,3,5-trimethyl-*d*-arabononitrile, m. about 2°; a by-product, m. 86.5°, $[\alpha]_D$ −40° ($CHCl_3$), is considered to be an *imino acid lactone;* the N is liberated quantitatively as NH_3 on heating with 2 *N* acid; alkali liberates NH_3 much more slowly. C. J. West

β-Methyl fructofuranoside. Hans Heinrich Schlubach and Heinz Eike Bartels. *Ann.* **541**, 76–85(1939); cf. S. and Rauchalles, *C. A.* **20**, 377.—Candiolin (15.41% H_2O, 17.05% Ca, 13.21% org. P) is treated with $(CO_2H)_2$, filtered from the Ca oxalate and then treated with brucine; crystn. of the ppt. from 7–8 parts boiling 70% EtOH (5 times) gives 75% of the brucine salt (I), $[\alpha]_D$ −23.6°, practically free of aldose components. I (80 g.) in 1100 cc. 20% EtOH and 23.1 g. $Ba(OAc)_2.H_2O$, shaken 10 min., 2250 cc. EtOH added, the ppt. removed with a centrifuge and dissolved in 300 cc. 1% ice-cold H_2O, EtOH and KOH added until the soln. is neutral, gives 90–5% of the Ba fructosediphosphate. Shaking the Ba salt (50 g.) in 1 l. 1.688% MeOH-HCl at 25° gives a mixt. of the 2 Me fructosides, which is sepd. into about equal wts. of 2 fractions, $[\alpha]_D$ 2.8–4.8° and −2 to −3°, by crystn. from a 1% aq. soln. Transformation into the brucine salt and crystn. from 96% (α-form) or 50% (β-form) EtOH finally yielded Ba salts with $[\alpha]_D$ 8.5° (H_2O, *c* 1) and $[\alpha]_D$ −8.75°, $[\alpha]_{5461}$ −10.4° (H_2O, *c* 1); the P was removed by kidney phosphatase at a pH of 9, giving 80–90% of Me fructofuranoside (II), which was purified through the Ac deriv. α-II has $[\alpha]_D$ 56.9° (MeOH, *c* 1.4); β-II, $[\alpha]_D$ −49.95°, $[\alpha]_{5461}$ −58.92° (H_2O, *c* 1). β-II is split to the extent of 95.1% by invertin in 36 hrs.; that 100% is not reached is probably due to the presence of some tetra-Ac

deriv.; α-II, 21.65% in 24 hrs. *N* HCl gives 97.2% splitting of the β-II in 36 hrs.; half-period, 52.5 min. The diphosphoric acids are not attacked to a noticeable degree by invertin in 17 hrs. C. J. West

Highly arylated compounds. IX. Highly arylated fulvenes. W. Dilthey and P. Huchtemann. *J. prakt. Chem.* **154**, 238–65(1940); cf. *C. A.* **32**, 1724³.—Tetracyclone (7 g.) and MeMgBr in ether, boiled 4 hrs., give 5.2 g. of *2,3,4,5-tetraphenyl-1-methylcyclopentadien-1-ol* (I), m. 195°; concd. H_2SO_4 gives a deep orange-red color. Passing a rapid stream of HCl into 30 g. of I in 300 cc. boiling AcOH for 1 hr. gives 26.4 g. of *2,3,4,5-tetraphenylfulvene* (II), fiery orange-red, m. 211–12°; it is pptd. unchanged from the deep orange-red H_2SO_4 soln.; it is unchanged on heating at 400° and is not rearranged to 1,2,3,4-$Ph_4C_5H_2$ on distn. *in vacuo*. II is also formed from I by concd. H_2SO_4 or $KHSO_4$ in AcOH, on melting with $KHSO_4$ or with P_2O_5 in C_6H_6. II is also formed in 0.9-g. yield from 1 g. of tetraphenylcyclopentadiene (III) and 25 cc. 40% HCHO with 25 cc. MeOH and 50 cc. 4% MeOK on boiling 2 hrs.; this is a convenient method of prepn. of fulvenes when the ketone is not easily accessible. When HCl is passed into 1 g. I in 20 cc. cold AcOH there results *2,3,4,5-tetraphenyl-1-chloro-1-methylcyclopentadiene*, amorphous, yellow-orange, m. 166–7°; this could not be converted to II. II and Br in $CHCl_3$ give a *dibromide*, citron-yellow, m. 147–8°; concd. H_2SO_4 gives a violet-red soln. II and Cl in ether give a *tetrachloride*, m. 149°; H_2SO_4 gives a blue soln., changing to red-violet. I could not be added to II. II and *p*-$ONC_6H_4NMe_2$ in C_5H_5N or C_5H_5N-EtOH with piperidine give the *dimethylaminophenylimine* of II, deep black-violet, m. 217–18°; the concd. H_2SO_4 soln. is deep violet, changing to a greenish yellow; the violet ether soln. is completely decolorized by Cl. II (10 g.) in 100 cc. dioxane, 1 g. KOH and 50 cc. 30% H_2O_2, boiled 2 hrs., give 9.5 g. of the *oxido deriv.* (IV), $C_{30}H_{22}O$, m. 227° (decompn.); concd. H_2SO_4 gives a violet and then a brown-red color. IV does not react with $NH_2OH.HCl$ or $H_2NNHCONH_2$; $PhMgBr$ gives II. The *1-Et analog* of I (prepd. from EtMgBr) m. 188°; the H_2SO_4 soln. is yellow-red with an orange fluorescence; the crystals turn yellow in the light; HCl in boiling AcOH gives the *6-Me deriv.* of II, orange-brown, m. 194–5°; the deep yellow-red H_2SO_4 soln. has an orange fluorescence; this fulvene adds H_2O. The 1-benzyl analog of I, greenish yellow, m. 156–7°; the concd. H_2SO_4 soln. is orange-red; it is light sensitive. MeONa in C_5H_5N gives an orange ppt.; heating with MeOH-KOH gives a green to blue soln. Loss of H_2O gives 2,3,4,5,6-pentaphenylfulvene, red, m. 200–1°, which also results from III and BzH with MeOK in MeOH (boiling 4 hrs.). III (1 g.) and 2 g. of *p*-$MeOC_6H_4CHO$ with MeOK give 1.1 g. of the *6-(p-anisyl) deriv.* of II, violet-brown, m. 197–8°, sol. in concd. H_2SO_4 with a violet-red color and brown-red fluorescence. III (1 g.) and 1.5 g. of *p*-$Me_2NC_6H_4CHO$ give 1 g. of the *6-(p-dimethylaminophenyl) deriv.* of II, red, m. 207–10°; the H_2SO_4 soln. is orange-red. III (1 g.) and 10 g. of Ph_2CCl_2, heated 15–20 min. at 190–5°, give 0.95 g. of *2,3,4,5,6,6-hexaphenylfulvene*, nearly black, m. 301–2°, sol. in concd. H_2SO_4 with a greenish blue or violet-red color. Triphenylcyclopentadiene (V) (1 g.) and HCHO with MeOK, boiled 2 hrs., give 0.97 g. of *2,4,5-triphenylfulvene*, yellow-red, m. 148° and sol. in concd. H_2SO_4 with a brown-yellow color. V and BzH give 2,4,5,6-tetraphenylfulvene, brown-red, m. 156°; H_2SO_4 gives a violet-brown color, gradually developing a green fluorescence. V and Ph_2CCl_2 (15 min. at 190–5°) give *2,4,5,6,6-pentaphenylfulvene*, brown-violet, m. 181°, sol. in concd. H_2SO_4 with a green to deep red color; org. solvents give deep red solns. Phenylcyclone (7 g.) and excess MeMgBr in ether give 3.9 g. of *2,5-diphenyl-3,4-(o,o'-biphenylene)-1-methylcyclopentadien-1-ol* (VI), yellow, m. 231–2°; concd. H_2SO_4 gives a violet-red color, changing to brown; heating 4 g. VI in AcOH and treatment with dry HCl for several hrs. give 1.8 g. of *2,5-diphenyl-3,4-(o,o'-biphenylene)fulvene*, orange-red, m. 239–40°; the concd. H_2SO_4 soln. is violet-red, changing to brownish red; Cl quickly decolorizes the red ether soln. Acecyclone (VII) (20 g.) and MeMgBr give 10.6 g. of *2,5-diphenyl-3,4-(1,8-naphthylene)-1-methylcyclopentadien-1-ol* (VIII), golden yellow, m. 197° (decompn.); the concd. H_2SO_4 soln. is violet; AcOH-HCl gives *2,5-diphenyl-3,4-(1,8-naphthylene)fulvene*, red-violet, m. 225–6°; the concd. H_2SO_4 soln. is orange-red. The color of VIII in ether is discharged by Cl and that in alk. dioxane by H_2O_2! VII (10 g.) and EtMgBr give 5 g. of the *1-Et analog* of VIII, yellow, m. 146°; $PhCH_2MgCl$ gives the *1-benzyl analog* of VIII, yellow, m. 234–5°. The relation between color and the structure of these compds. is discussed. C. J. West

Action of radon on polymethylenes—cyclobutane and cyclobutene. G. B. Heisig. *J. Phys. Chem.* **43**, 1207–12 (1939); cf. *C. A.* **30**, 384⁹.—Cyclobutane and cyclobutene polymerize to liquids which increase in color and viscosity with time of bombardment by α-particles. $-M/N$ was 2.3 for cyclobutane and 7.4 for cyclobutene, with a heat of formation of 16.8 and −6 cal., resp. In the prepn. of the hydrocarbons, cyclobutylamine is made directly from cyclobutanecarboxylic acid. This increases the final yield of hydrocarbons threefold. H. E. Phipps

Spiro compounds. I. Preparation of cyclopentane-*spiro*-cyclopentanone and cyclohexane-*spiro*-cycloheptanone. Muhammad Qudrat-i-Khuda and Amalendu Kumar Ray. *J. Indian Chem. Soc.* **16**, 525–31(1939).—The reduction of cyclopentanone (I) and cyclohexanone (II) with Mg and Al amalgams gives diols which undergo pinacolone rearrangement to spiro ketones, easily transformed into hydrocarbons required for heat of combustion studies into the nature of spiro compounds. A suspension of 13.5 g. $HgCl_2$ in 90 cc. I was added to 100 cc. of boiling benzene contg. 12 g. of Mg powder. The mixt. was refluxed for 1 hr., dild. with 30 cc. H_2O and refluxed for 1 more hr. The filtered soln. and benzene washings were evapd. down, cooled and treated with petr. ether, yielding 14–15 g. of colorless needles of bicyclopentane-1,1′-diol (III), $C_{10}H_{18}O_2$, m. 109°, and a secondary product, oily cyclopentylidenecyclopentanone (IV), b_5 108–10°; semicarbazone, m. 224°. By substituting Al for Mg powder the yield from 90 cc. I is increased to about 19 g. III, together with some IV. Rearrangement of 20 g. III by heating with 150 cc. of 20% H_2SO_4 at 120–5° for 2 hrs. and extg. the distn. product with ether gave 16 g. of cyclopentane-*spiro*-cyclohexan-2-one (V), b_{45} 120°; semicarbazone, m. 189–90°; *monobenzylidene deriv.*, $C_{17}H_{20}O$, m. 75°. Oxidation of 18 g. V by heating with 45 cc. HNO_3 and 12 cc. H_2O gave 19 g. of *1-carboxycyclopentane-1-butyric acid* (VI), m. 192°; *di-Et ester* (VII), $C_{14}H_{24}O_4$, b_6 140–2°, $d_4^{22.1}$ 1.017, $n_D^{22.1}$ 1.449, M. R. 67.59 (calcd. 67.96). A mixt. of 20 g. VII and 50 cc. abs. alc. contg. 1.8 g. Na was refluxed for 6 hrs., concd., dild. and neutralized with HCl. The oily layer was extd. with ether, yielding 11 g. of *Et cyclopentane-spiro-cyclopentan-2-one-3-carboxylate* (VIII), $C_{12}H_{18}O_3$, b_5 127°, $d_4^{24.8}$ 1.033, $n_D^{23.8}$ 1.451, M. R. 54.75 (calcd. 54.88). VIII was heated with 10% HCl for 4 hrs. and the product was extd. with ether and distd., giving *cyclopentane-spiro-cyclopentanone* (IX), $C_9H_{14}O$, b_{32} 115°, $d_4^{22.1}$ 0.9891, $n_D^{22.1}$ 1.471, M. R. 39.1 (calcd. 39.4); *semicarbazone*, m. 214°; *benzylidene deriv.*, m. 64°. Reduction of 200 g. of cyclohexanone with Al-Hg gave some cyclohexylidenecyclohexanone (X) and 58 g. of bicyclohexane-1,1′-diol, m. 130°, transformed by heating with H_2SO_4 to a mixt. of bicyclohexenyl and the pinacolone, b_6 110–14°. Treatment with $H_2NNHCONH_2.AcOH$, filtration and extn. with ether gave 1,1′-bicyclohexenyl, b_6 111°, and *cyclohexane-spiro-cycloheptanone semicarbazone*, m. 216–17°, regenerating the *ketone* (XI), $C_{12}H_{20}O$, b_8 120°, $d_4^{22.8}$ 0.9795, $n_D^{23.8}$ 1.483, M. R. 52.64 (calcd. 53.22); *benzylidene deriv.*, m. 123°. A mixt. of 4.2 g. $NCCH_2CONH_2$ and 1.14 g. Na in alc. and 7.5 g. IV was refluxed for 3 hrs., distd., dild. and acidified with HCl. Recrystn. of the ppt. from dil. alc. yielded 6 g. of a *condensation product*, $C_{13}H_{18}N_2O_2$, m. 215.6°. A similar *condensation product*, $C_{16}H_{20}N_2O$ (*C. A.* **24**, 4767), was obtained from X. II. **Synthesis of cyclopentane-*spiro*-cyclopentanone.** Muhammad Qudrat-i-Khuda and Asutosh Mukherjee. *Ibid.* 532–5(1939).—The constitution of IX has been confirmed by an independent synthesis

from the anhydride of 1-carboxycyclopentane-1-acetic acid (XII). A mixt. of 100 g. XII, 75 cc. Ac_2O and 15 cc. AcCl was distd. under reduced pressure, yielding 80 g. of the *anhydride*, b_{18} 174°, reduced by Na in alc. to 55 g. of *lactone* (XIII), $C_8H_{12}O_2$, b_{40} 154°, $d_4^{20.1}$ $n_D^{20.1}$ 1.46345, M. R. 35.9 (calcd. 36.3). Treatment of 80 g. XIII with PBr_5 at 100° for 2 hrs. produced 62 g. of *Et 1-bromoethylcyclopentane-1-carboxylate* (XIV), b_5 118°, $d_4^{20.1}$ 1.2481, $n_D^{20.1}$ 1.46816, M. R. 55.46 (calcd. 55.48). Condensation of 55 g. XIV with $NaCH(CO_2Et)_2$ from 32 g. $CH_2(CO_2Et)_2$ and 4.6 g. Na gave the tricarboxylic ester, *Et 1-carbethoxycyclopentane-1-α-carbethoxybutyrate*, $C_{17}H_{28}O_6$, b_6 154°, $d_4^{21.1}$ 1.05401, $n_D^{21.1}$ 1.44486, M. R. 82.7 (calcd. 83.1), hydrolyzed by heating 25 g. with 100 cc. of concd. HCl for 14–16 hrs. to VI; *dianilide*, m. 163°. The ester, VII, was condensed to VIII and hydrolyzed to IX, which was also obtained by the dry distn. of VI in the presence of $Ba(OH)_2$. C. R. Addinall

High-pressure hydrogenation of benzene. I. Experiments carried out by employing a revolving autoclave. Singo Andō. *J. Soc. Chem. Ind., Japan* 42, Suppl. binding 391–3(1939).—Treatment of C_6H_6 and cyclohexane (300 g.) at 430–440° with H (80–90 atm. initial pressure at 0°) for 1–2 hrs. in the presence of a catalyst composed of 5 g. S and 30 g. MoO_3 (dried after HNO_3 pptn. from hot NH_4 molybdate soln. and water-washing) resulted in nearly quant. yields of oily products composed of 0.2–0.7% unsatd. hydrocarbons (sol. in 86% H_2SO_4), 0–80.8% aromatic hydrocarbons (sol. in 100% H_2SO_4) and 18.9–99.6% satd hydrocarbons. No CH_4 was produced, and the quantities of cyclopentane and hexane formed were almost negligible. The satd. hydrocarbons formed from C_6H_6 were preponderantly methylcyclopentane, with some cyclohexane; those found in the case of cyclohexane contained only 11.9–16.8% methylcyclopentane, the balance being unchanged cyclohexane. Thus the mechanism of hydrogenation of C_6H_6 does not consist wholly of the primary formation of cyclohexane, followed by isomerization of the latter, but probably is as follows: C_6H_6 → cyclohexene → (1) methylcyclopentane and (2) cyclohexane, followed by isomerization of the latter to methylcyclopentane. George Ayers

Isomerization of cyclohexane under high pressure of hydrogen. Singo Andō. *J. Soc. Chem. Ind., Japan* 42, Suppl. binding 322–4(1939); cf. *C. A.* **33**, 3564².—Cyclohexane was charged continuously in 2 runs, resp., into a vertical reaction chamber (contg. Mo sulfide catalyst, prepd. by adding H_2SO_4 to a soln. of MoO_3 in NH_4 sulfide, supported on 5 parts of granular Japanese acid clay which had been activated by mineral acids) at rates of 145 and 113 cc./hr. and at a pressure of 200 atm. at temps. of 379° and 411°, yielding products contg. 0.8% and 0.4% unsatd. hydrocarbons, 0.1% and 0.6% aromatic hydrocarbons and 99.1% and 99.0% satd. hydrocarbons, but no CH_4. The main fractions of the satd. hydrocarbon fractions were shown by elementary analysis, b. p., d, *n* and aniline point detns. to be composed almost wholly of cyclohexane and methylcyclopentane, there being 35.4% and 79.4% methylcyclopentane, resp., in the above main fractions. George Ayers

Enium. XXXV. Oxidation of ketones with perhydrol. W. Dilthey, Maryke Inckel and Horst Stephan. *J. prakt. Chem.* **154**, 219–37(1940); cf. *C. A.* **33**, 4257².—Previous work by D., Quint and Dierichs (*C. A.* **32**, 5781⁸) showed that carbenium salts of all kinds were easily and smoothly oxidized by H_2O_2. Ketones yield such salts with acids but they are relatively unstable and a relatively high acid concn. is necessary to keep them in soln. Dropwise addn. of 20 g. cyclohexanone (I) to a mixt. of 50 g. Ac_2O, 20 g. 96% H_2SO_4 and 25 g. 30% H_2O_2 at 15° and stirring an addnl. 2 hrs. give 9 g. (45%) of the *peroxide* (II) of I, m. 128–9°; II also results by addn. of 20 g. I in 20 g. AcOH to a mixt. of 30 g. 30% H_2O_2, 25 g. 96% H_2SO_4 and 25 g. Ac_2O at 20°; crystn. from benzine (40–60°) gives a II, m. 132–3°. II is relatively stable and detonates only on percussion; acids regenerate I and H_2O_2. Heating II does not give ω-hydroxycaproic acid (III). A mol.-wt. detn. indicates the formula $(C_6H_{10}O_3)_2$. If in the above expts. the Ac_2O is replaced by an equal wt. of concd. H_2SO_4 a very vigorous reaction occurs and there results a little II and a good yield of polymeric III, m. 51–3° (hydrazide, m. 117°). The 4-Me deriv. of I (20 g.) gives 7 g. of the *4-Me deriv.* of II, m. 71–2°. The *2-Me deriv.* of II m. 106–7° (yield, 1 g. from 20 g. of the 2-Me deriv. of I). Cyclopentanone, as above, gives 2.5 g. of a *peroxide*, m. 172° (decompn.), and after pouring the filtrate into H_2O 1 g. of a *peroxide*, m. 105°; the use of H_2SO_4 in place of Ac_2O causes a violent reaction without the formation of a peroxide; the 3-Me deriv. also gives a peroxide but in poor yield. Me_2CO gives a dimeric peroxide, m. 132°; pinacolone, mesityl oxide and camphor do not yield peroxides. $PhCH_2CH_2Ac$ gives a *peroxide*, $(C_{10}H_{12}O_3)_2$, m. 102–3°; *that* from Pr_2CO, $(C_7H_{14}O_2)_2$, m. 47–8°. PhAc gives $(C_8H_8O_2)_2$, m. 185–6°; Ph_2CO gives BzOPh, m. 70–1°. EtAc, (iso-Bu)$_2$CO, Et_2CO and PrAc give liquid peroxides. *p*-$MeOC_6H_4CHO$ and *p*-HOC_6H_4CHO give black-brown tars. *o*- and *m*-$O_2NC_6H_4$-CHO give the corresponding acids. *l*-Menthone (IV) does not yield a peroxide, the oxidation products being those observed by Baeyer and Villiger (*Ber.* **32**, 3619 (1899)). The lactone or Et ester of 2,6-dimethyl-3-hydroxyoctanoic acid (from IV) and PhMgBr give a nearly quant. yield of *1,1-diphenyl-3,7-dimethyl-1,6-dihydroxyoctane*, m. 91°; the H_2SO_4 soln. shows a yellow halochromy. *d*-Isomenthone also does not yield a peroxide. The mechanism of the oxidation of a CO compd. with H_2O_2 is discussed. C. J. West

Photochemical reactions of oxalyl chloride and phosgene with cyclohexane. M. S. Kharasch and Herbert C. Brown. *J. Am. Chem. Soc.* **62**, 454(1940).—A preliminary note reports that 25.2 g. cyclohexane and 9.6 g. $(COCl)_2$, illuminated by a 300-w. W lamp placed immediately below the flask (gentle refluxing is caused by the heat) for 24 hrs., give 4.1 g. of cyclohexanecarbonyl chloride (4.2 g. $(COCl)_2$ had reacted); calcd. yield, 4.8 g. $COCl_2$ behaves similarly. The gases evolved consist of an equal mixt. of CO and HCl. C. J. West

Synthesis of compounds related to the antirachitic vitamins. II. John B. Aldersley, G. Norman Burkhardt, Albert E. Gillam and Nathan C. Hindley. *J. Chem. Soc.* **1940**, 10–16; cf. *C. A.* **32**, 4959¹.—Quinitol diacetate (I) (50 g.) in 50% EtOH at 40–50°, treated with 11 g. KOH in 50% EtOH during 5 min. (vigorous stirring), the EtOH removed *in vacuo* and the aq. soln. extd. with $CHCl_3$, gives 60% of the *monoacetate* (II), b_{15} 136–7°, m. 68–72°; oxidation in the cold with CrO_3 in AcOH gives from 22 g. II 15 g. *4-acetoxycyclohexanone* (III), b_8 110°, b_{14} 124–6°, b_{760} 235° (*semicarbazone*, m. 182°; *2,4-dinitrophenylhydrazone*, m. 176°). Crude III (contg. 16% I) (50 g.) with 2 *N* NaOH at room temp. for 24 hrs. gives 28 g. of *4-hydroxycyclohexanone* (IV), $b_{0.6}$ 83–5°, and some quinitol (V); acetylation of IV gives III, b_{11} 112–14°. Oxidation of V with CrO_3 in Ac_2O at 10–15° (standing overnight) yields 67% III and some I and 1,4-cyclohexanedione. Passing HCl into III and BzH in AcOH gives *4-acetoxy-2,6-dibenzylidenecyclohexanone*, m. 165°; no monobenzylidene deriv. was formed. 1-Allylcyclohexanol in AcOH, treated with O_3 for 20 hrs. and the ozonide warmed with Zn dust, gives 35% of cyclohexylideneacetaldehyde (VI), b_9 85–7°, showing a single absorption band in EtOH at 2400 A., ϵ_{max} 15,900. IV (36.4 g.) in 0.086 *N* NaOH, shaken in N with 28.2 g. VI (added in 5 equal parts during 24 hrs. and the shaking continued for an addnl. 24 hrs.), the mixt. neutralized with H_2SO_4 and the yellow oil taken up in Et_2O, gives 21 g. of a thick yellow oil, $b_{0.01}$ 168–73°, from which crystd. *2-keto-5-hydroxy-α,β-dicyclohexylideneethane* (VII), m. 65–9°, absorption max. at 3090 A., ϵ_{max} 23,200 in EtOH; *2,4-dinitrophenylhydrazone*, m. 170–1°; *phenylurethan*, m. 180°. Refluxing VII with Ac_2O in N gives the *acetate*, m. 80–2°, absorption max. 3090 A., ϵ_{max} 23,300 (*2,4-dinitrophenylhydrazone*, deep red, m. 187–9°; the semicarbazone is pale yellow, m. 205–10° (decompn.) and is very sensitive to air, turning deep yellow; absorption max. at 3120 A., ϵ_{max} 22,030). VII (2 g.) and MeMgI give a product $b_{0.003}$ 140–50°, a viscous, pale yellow oil, with a

single absorption band at 2815 A., $\epsilon_{max.}$ 24,500; the phenylurethan (VIII), after repreated crystn. from dil. Me_2CO, m. 125–35°; after 2 crystns. (m. 105–27°), it showed 2 absorption bands, 2770 A. and 2390 A., $\epsilon_{max.}$ 38,150 and 20,900; exposure to air caused a broadening of the m.-p. range. Distn. of VIII in a high vacuum gives a sublimate, m. 123–32°, and showing 2 absorption bands at 2770 and 2390 A., $\epsilon_{max.}$ 40,780 and 23,000. The acetate of VII, treated with $BrCH_2CO_2Et$ and Zn, the product successively hydrolyzed with dil. alkali and dehydrated with Ac_2O, the Ac group removed and the unsatd. acid decarboxylated, gives a *hydroxytriene*, $b_{0.002}$ 140–55°, pale yellow and showing a single absorption band in EtOH at 2805 A., $\epsilon_{max.}$ 28,000; the phenylurethan, m. 123–32°, is apparently identical with VIII; it exhibits 2 bands at 2805 and 2380 A., $\epsilon_{max.}$ 40,440 and 24,260; the 3,5-dinitrobenzoate m. 70°. The triene showed no antirachitic activity. Heating VII with piperidine-AcOH for several hrs. gave no indication of cyclization to a hydroxyoctahydrophenanthrene. Reduction of VII with $(iso\text{-}PrO)_3Al$ in iso-PrOH (refluxing overnight) gives a *compd.*, $C_{14}H_{20}O$, m. 81–3°, with 0.96 active H atom, absorption max. at 2705 and 2820 A., $\epsilon_{max.}$ 42,100 and 40,900. C. J. W.

Cyclization of vitamin A_2. Norris D. Embree and Edgar M. Shantz. *J. Biol. Chem.* **132**, 619–26(1940); cf. *C. A.* **33**, 3969⁸.—Like vitamin A_1, vitamin A_2 is cyclized by treatment with dry alc. HCl and the cyclized product has the same ultraviolet absorption spectrum as cyclized vitamin A_1, with max. at 350, 368 and 390 mμ. The $SbCl_3$ reaction product of both the cyclized and uncyclized vitamin A_2 has a spectrum with a max. near 690 mμ. Cyclized A_2 is more strongly adsorbed by alumina than cyclized A_1. A method is described for *the estn. of the relative amts. of vitamins A_1 and A_2 by the sepn. of their cyclized derivs.* A. P. Lothrop

Action of aluminum chloride on aromatic hydrocarbons. II. The 1,3-dimethyl-4-propylbenzenes. Dorothy V. Nightingale and Benoist Carton, Jr. *J. Am. Chem. Soc.* **62**, 280–3(1940); cf. *C. A.* **33**, 1681⁷.—*m*-Xylene (I), EtCOCl and $AlCl_3$ in CS_2 give 80% of the 4-propionyl deriv., b_{10} 112°; Clemmensen reduction yields 50% of *1,3-dimethyl-4-propylbenzene* (II), b_{23} 95°, n_D^{25} 1.4995; II also results in 40% yield from I and cyclopropane with $AlCl_3$ at 0–15°. I (375 cc.) and 47 cc. iso-PrOH, cooled with ice and treated during 2 hrs. with stirring with a mixt. of 500 cc. concd. H_2SO_4 and 110 cc. H_2O, with stirring for 14 hrs. at room temp., give 75% of *1,3-dimethyl-4-isopropylbenzene* (III), b_{13} 77°, n_D^{25} 1.4998. I (53 g.) and 15 g. $AlCl_3$, treated during 1 hr. with 20 g. iso-PrCl and stirred for an addnl. 3 hrs., give 40% of *1,3-dimethyl-5-isopropylbenzene* (IV), b_{17} 83–5°, n_D^{25} 1.4930; PrCl gives 46% of impure IV and C_6H_6 and HCO_2Pr give 50% of IV. Addn. of 1363 cc. concd. H_2SO_4 to 1060 cc. AcPr and 1406 cc. Me_2CO at 0–10° gives 19 g. of *1,3-dimethyl-5-propylbenzene* (V), b_{18} 90–1°, n_D^{26} 1.4913. The Na deriv. of mesitylene (80 cc.) and 78 g. EtI give 5.5 g. V. The *diacetamido derivs.* m. as follows: II 284°, III 292°, IV 295°, V 239°. III undergoes rearrangement on warming with $AlCl_3$ at 55° for 3 hrs. to yield principally IV; II is largely rearranged by $AlCl_3$ at 100° for 4 hrs. to yield IV; at 85–90° the trialkyl fraction is a mixt. and at 55° II is largely unchanged. The formation of II from I and cyclopropane and of IV from HCO_2Pr supports the view of Smith and Perry (*C. A.* **33**, 6257⁷) that a 1,3,4-substituted hydrocarbon is the initial product of the reaction when I is alkylated in the presence of $AlCl_3$. C. J. West

Synthesis of styrene. A. G. Bulavskiĭ. *Org. Chem. Ind.* (U. S. S. R.) **6**, 434–7(1939).—Some addnl. data are given on the catalytic dehydrogenation of PhEt to styrene by the previous method (cf. Zal'kind and Bulavskiĭ, *C. A.* **30**, 1368⁵). Chas. Blanc

Styrene, iodine and organic disulfides. Bror Holmberg. *Arkiv Kemi, Mineral., Geol.* **13B**, No. 14, 6 pp.(1939)(in German); cf. *C. A.* **33**, 4155⁶.—As previously shown for $(SCH_2CO_2H)_2$ (I), its di-Et ester (II), Me_2S_2 (III), Et_2S_2 (IV) and Ph_2S_2 (V) add to PhCH:CH_2 (VI) under the catalytic influence of I. Tri- and tetrathiodiglycolic acids also react with the formation of tars. No reaction occurs between VI and $(AcS)_2$ or dixanthogen or between I and members of the series PhCH:$CHCH_2R$ (R = OH, Br, EtO, PhO, SCH_2CO_2H), PhCH:CHCHO and its mercaptalacetic acid, PhCH:$CHCO_2H$ and its Et ester, PhCH:CHCOMe or PhCOCH:CHPh. If a solvent is necessary abs. ether is best, then C_6H_6, ordinary ether, CS_2, Me_2CO and AcOH. *Styrene bis(methyl sulfide)*, prepd. in 17.2-g. yield by allowing 12 g. of VI, 12 g. of III, and 0.5 g. of I to stand 2 days at room temp., washing with *N* NaOH and distg. at low pressure, b_{10} 149–50°, d_4^{20} 1.096. Oxidation of 5 g. in 25 cc. of Me_2CO with 6 g. of 30% H_2O_2 gives *styrene bis(methyl sulfoxide)*, crystals from AcOEt, m. 122–4°; also, in small amt. another substance, m. 130–1°, possibly a diastereoisomer. Similarly, 18.5 g. of VI, 21 g. of IV and 0.5 g. of I give, after retreatment of 15 g. of the fore-run with I for 10 days, 25 g. of *styrene bis(ethyl sulfide)*, b_{11} 163–4°, d_4^{20} 1.046. *Styrene bis(thioglycolic Et ester)*, about 7 g. from 5.2 g. of VI, 12 g. of II and 0.5 g. of I, allowed to stand 1 week, b_3 210–12°. *Styrene bis(phenyl sulfide)*, 12 g. from 5.2 g. of VI, 11 g. of V and 1 g. of I in 25 cc. of abs. ether, allowed to stand 2 days, m. 57–8°. H. L. Mason

The association of the nitrotoluenes. Walter Hückel and Maria v. Schalscha-Ehrenfeld. *J. prakt. Chem.* **154**, 57–65(1939).—All 3 nitrotoluenes show (1) approx. the same mol.-wt. values (cryoscopic detn. in C_6H_6), (2) approx. the same increase in mol. wt. with increase in concn. (larger increase in mol. wt. with concn. in cyclohexane than in C_6H_6), and (3) approx. the same increase in mol. wt. for the different concns. of *p*-$O_2NC_6H_4Me$ in C_6H_6 or cyclohexane by both b.-p. and m.-p. methods. The degree of assocn. of the 3 nitrotoluenes is not detd. by the magnitude of the dipole moment. In comparison with $PhNO_2$, the 3 nitrotoluenes show a similar rise in mol. wt. with concn. in C_6H_6, but in cyclohexane the nitrotoluenes give the greater rise, showing greater assocn. α-$C_{10}H_7NO_2$ shows a greater increase of mol. wt. with concn. in C_6H_6 (f.-p. method) than does $PhNO_2$. In cyclohexane, α-$C_{10}H_7NO_2$ shows approx. the same mol.-wt. increase with concn. by both b.-p. and f.-p. methods. B.-p. detns. of the mol. wt. of *trans*-β-decalol were made in C_6H_6 and cyclohexane to find out the effect of volatility (negligible with C_6H_6; perceptible with cyclohexane) of alcs. b. above 200° on the detn. F.-p. detns. of mol. wt. of α-fenchol in C_6H_6 and cyclohexane show a considerable increase in assocn. with increase in concn. in cyclohexane, but only a small increase in assocn. in C_6H_6 (similar to that shown by isoborneol). George Ayers

Exchange reactions of nuclear hydrogen atoms of aniline hydrochloride in aqueous solution. I. The reaction in neutral and acid solution. Masao Koizumi. *Bull. Chem. Soc. Japan* **14**, 530–9(1939); cf. *C. A.* **31**, 97⁵.—The rate of the reaction was studied. On the assumption that the reaction is bimol., the rate const. is almost independent of the concn. of $PhNH_2.HCl$ and of acid. The proposed mechanism is: $PhNH_2 + H_3DO^+ = C_6H_4DNH_2 + H_3O^+$. G. M. Murphy

Halogen-metal interconversion with *m*- and *p*-bromodimethylanilines. Henry Gilman and Irving Banner. *J. Am. Chem. Soc.* **62**, 344–5(1940).—Details are given of the prepn. of *o*- (70%), *m*- (54%) and *p*-$BrC_6H_4NMe_2$. Refluxing 0.04 mole of the *m*-isomer with 0.055 mole of BuLi in Et_2O (N atm.) for 20 hrs. and carbonating give 26–32% of *m*-$Me_2NC_6H_4CO_2H$ and 1.1 g. of an oil b_{13} 90–115°. The *p*-isomer similarly gives 41–56% of *p*-$Me_2NC_6H_4CO_2H$. The yields could probably be increased by decreasing the time of refluxing. C. J. West

Industrial synthesis of arsines. Synthesis of benzenearsonic acid. Louis Blas. *Génie civil* **115**, 448–9(1939).—The reaction of Na_3HAsO_3 on PhN_2Cl is greatly influenced by the diln. of the arsenite, the speed of reaction, and especially by the pH of the soln. (which should remain const.). All compds., like Na_2CO_3, which play the role of buffer tend to increase the yield. A. N. Hird

***p,p'*-Diaminodiphenylarsinic acid.** G. Gilta. *Bull. soc. chim. Belg.* **48**, 444–6(1939); cf. *C. A.* **13**, 1858.—A mixt. of 80 g. *p*-arsanilic acid (I) and 500 g. $PhNH_2$ is

heated at 220°, extd. with 10% NaOH, and the ext. washed with Et_2O; acidification of the alk. soln. to methyl orange by concd. HCl pptd. a mixt. of unreacted I and *p,p'*-diaminodiphenylarsinic acid (II). Treatment of this mixt. with satd. NaOAc soln. removes I as the Na salt, and II is obtained as colorless, monoclinic needles; yield, 5 g. The crystallographic consts. and optical properties of II are described. David E. Adelson

Sulfonation and nitration reaction promoted by boron fluoride. R. J. Thomas, W. F. Anzilotti and G. F. Hennion. *Ind. Eng. Chem.* **32**, 408–10(1940).—BF_3 is an effective promoter and dehydrating agent for sulfonation and nitration reactions. When water is a product of the reaction BF_3 may drive the reaction to completion by combining with the water produced to form $BF_3.H_2O$. At completion of the reaction, enough water may be added to form $BF_3.2H_2O$, which can then be sepd. from the reaction products by distn. *in vacuo*. The BF_3 can be recovered in several ways, e. g., by forming $Ca(BF_4)_2$ and heating it to release BF_3. Directions are given for sulfonating benzene, toluene, naphthalene and phenol, for disulfonating carbazole and biphenyl, and for nitrating nitrobenzene, *p*-toluenesulfonic acid, benzoic acid, Me benzoate, and phthalic anhydride, and for successive sulfonation and nitration of benzene and toluene. F. L. Browne

Preparation of *m*-nitrobenzenesulfonyl chloride by nitration of benzenesulfonyl chloride. I. G. Gurdzhi. *Org. Chem. Ind.* (U. S. S. R.) **6**, 253–4(1939).—A yield of 89% $m\text{-}O_2NC_6H_4SO_2Cl$, m. 61–1.5°, was obtained from $PhSO_2Cl$ by treating it with 6 parts by wt. of 16% oleum and 30% excess of HNO_3, d. 1.38, at 0° and allowing the mixt. to stand for 3 days at room temp. The product, recrystd. from ether or alc., is free from *o*- and *p*-isomers. Chas. Blanc

Some new applications of magnesium in organic synthesis. III. Acylation of phenols in the presence of magnesium and preparation of phenolic esters. Aleksand'r Spasov. *Ann. univ. Sofia II. Faculté phys.-math.*, Livre 2, **35**, 289–93(in German, 294–5)(1938–39); cf. *C. A.* **32**, 1243⁹.—The reaction of phenols with acid chlorides takes place more smoothly in C_6H_6 soln. in the presence of Mg, which does not, however, react with all of the HCl formed as in the acylation of tertiary alcs. The phenol (0.1 mol.) in 20–25 g. C_6H_6, Mg turnings (1.2 g. for each HO group) and 0.1–0.12 mol. acyl chloride were heated 0.5–1.0 hr. at 90° in a round flask; the reaction product was dild. with ether and the ether soln. decanted from the unchanged Mg, which was then washed with ether. The residue in the flask was treated with H_2O and the mixt. filtered into the C_6H_6-Et_2O soln. through a wire gauze. After shaking successively with water, dil. caustic alkali and water, the soln. was dried over Na_2SO_4 and the ether removed by distn. The residue, if liquid, was distilled *in vacuo;* if solid, it was crystd. from a suitable solvent. Yields of esters were: AcOPh, 92%; $EtCO_2Ph$, 92%; $PrCO_2Ph$, 98%; $PhCH_2CO_2Ph$, 93%; BzOPh, 93%; *o*-$AcOC_6H_4Me$, 98%; *p*-$AcOC_6H_4Me$, 95%; *o*-iso-$PrCO_2C_6H_4Me$, 98%; 1,3,6-$AcOC_6H_3Me$-iso-Pr, 97%; 1,3,6-$PrCO_2C_6H_3Me$-iso-Pr, 97%; *p*-$AcOC_6H_4NO_2$, 96%; *m*-$C_6H_4(OAc)_2$, 92%; *p*-$C_6H_4(OAc)_2$, 95%; 1,3,5-$C_6H_3(OAc)_3$, 71%; α-$AcOC_{10}H_7$, 96%; β-$AcOC_{10}H_7$, 96%; and α-iso-$PrCO_2C_{10}H_7$, 93%. George Ayers

Alkaline fusion (in organic synthesis). N. N. Vorozhtsov. *Org. Chem. Ind.* (U. S. S. R.) **6**, 299–300(1939).—A comprehensive discussion of the theory and practice of alk. fusion in the synthesis of org. compds., based on the literature. 60 references. **By-products of alkaline fusion of benzenesulfonic acid in the production of phenol; their separation and utilization.** M. V. Troitskiĭ. *Ibid.* 301–3.—A review of literature with 50 references. Chas. Blanc

Iodination of a few halogenated phenols. Phuldeo Sahay Varma and K. M. Yashoda. *J. Indian Chem. Soc.* **16**, 477–8(1939).—Iodination of halogenated phenols has been effected by means of I in KI in the presence of concd. NH_4OH (*C. A.* **11**, 1425). Addn. of 7.8 g. I in KI to *p*-ClC_6H_4OH (4 g.) in 20 cc. concd. NH_4OH, shaking and letting stand for 30 min., acidification and crystn. from $CHCl_3$ gave 7 g. of 4,2-$ClIC_6H_3OH$, m. 78°; *Ac deriv.*, m. 57°; *Bz deriv.*, m. 83–4°; *picrate*, m. 68°. A similar iodination, continued until the color of I persisted, gave 4,2,6-$Cl_2IC_6H_2OH$, m. 108°; *Ac deriv.*, m. 128°. Iodination of 2,4-BrMeC_6H_3OH and 4,2-Br-MeC_6H_3OH yielded *2-bromo-6-iodo-p-cresol*, m. 46° (*Bz deriv.*, m. 115°), and *4-bromo-6-iodo-o-cresol*, m. 49° (*Ac deriv.*, m. 40°; *Bz deriv.*, m. 85°). C. R. Addinall

Halogen displacement and removal from aromatic halogen compounds under the influence of catalysts. Hans Meerwein, Paul Hofmann and Friedrich Schill. *J. prakt. Chem.* **154**, 266–83(1940).—2,4-$(MeO)_2C_6H_3I$ (I) is transformed into a mixt. of 1,3,4,6-$(MeO)_2C_6H_2I_2$ (II) and *m*-$C_6H_4(OMe)_2$ under a variety of conditions. I (10 g.) and 20 cc. $BF_3.Et_2O$ on standing 18 hrs. at room temp. give 5.8 g. (80%) II and 2.9 g. III. $TiCl_4$ gives 50% II, $AlCl_3$ 61% II, HCO_2H at 96° for 20 min. 48% II, 10% EtOH-HCl (8 days) 42% II, chlorocymenesulfonic acid in AcOH (3 days at room temp.) 73% of II, and P_2O_5 in C_6H_6 (15 hrs.) 54% II. Heating 3 g. II and 10 g. III with 3 g Cl_3CCO_2H at 120° for 5 hrs. gives 88% I; in HCO_2H for 12 hrs. at 90–5° there results only 10% I. I does not result from III with elementary I. I (20 g.), 100 cc. PhOMe and 20.7 g. Cl_3CCO_2H, heated 9 hrs. at 120°, give 83.3 g. of PhOMe, 4.4 g. *p*-IC_6H_4OMe, 1.8 g. of an oil probably contg. *o*-IC_6H_4OMe, 4.6 g. III, 0.6 g. I and 1.5 g. II. This indicates that the reaction is intermol. I, PhOH, $CHCl_3$ and BF_3, 3 weeks at room temp., give a small quantity of *o*-IC_6H_4OH. 2,4-$(MeO)_2C_6H_3Br$ with $BF_3.Et_2O$ gives 73% of the di-Br deriv.; 2,3-$(MeO)_2C_6H_3Cl$ reacts less readily and the reaction mixt. with BF_3 must be heated at 132–9° for 55 min. 1,3,4-$C_6H_3(OMe)_3$ (168 g.) in 250 cc. MeOH, treated with 254 g. I and 210 g. HgO in portions, gives *2,4,5-trimethoxyphenyl iodide* (IV), m. 70–1°. Shaking 5.81 g. IV with 10 g. $BF_3.Et_2O$ for 5 min. gives a quant. yield of $[2,4,5\text{-}(MeO)_3C_6H_2]_2$ (V); the same reaction occurs on heating IV with HClO at 75° (96% I split off in 7 hrs.), with Cl_3CCO_2H in CCl_4 (complete in 45 min.), and to some extent on boiling IV in decalin for 3 hrs. (20% I removed). The I in IV may be replaced by Br in CCl_4 (93% of the Br compd. in 80 min.); Cl gives V. Expts. with 5,2,4-$Me(MeO)_2C_6H_2I$ have not led to pos. results. The mechanism of the halogen wandering is discussed. C. J. West

Steric hindrance in ketone-phenol condensations. The condensation of guaiacol with cyclic ketones. Joseph B. Niederl, Victor Niederl and Joseph Gruner. *J. Am. Chem. Soc.* **62**, 320–2(1940); cf. *C. A.* **33**, 6839¹.—Previous work showed that, while the usual condensation product is an alkylidenediphenol, this is not formed when a reaction system is selected which would lead to the formation of a cycloalkylidenediphenol in which there is a substituent group in the *o*-position to either 1 of the 2 reacting C atoms involved in the condensation. To test this hypothesis a phenolic compd. having an alkoxy group in the *o*-position to the free HO group was condensed with cyclic ketones. *o*-HOC_6H_4OMe (I) (1 mole) and cyclohexanone (II) (0.5 mole) in 100 cc. AcOH, treated with dry HCl for 6 hrs. at room temp. on 2 consecutive days and allowed to stand 4 weeks at room temp., give 31% of *1,1-bis(3'-methoxy-4'-hydroxyphenyl)cyclohexane* (III), m. 174°; *phenylurethan*, m. 153°; *acetate*, m. 157°; *benzoate*, m. 168°; refluxing III with 48% HBr gives I; HI (d. 1.7) gives catechol. I and the *p*-Me deriv. of II give 10% of the *4-methylcyclohexane analog* of III, m. 165°; *phenylurethan*, m. 192°; *acetate*, m. 136°; *benzoate*, m. 162°. I and the *m*-Me deriv. of II give 27% of the *3-methylcyclohexane analog* of III, m. 149°; *phenylurethan*, m. 187°; *acetate*, m. 118°; *benzoate*, m. 171°. I and the *o*-Me deriv. of II (0.5 mole of each), treated as above and also on the water bath for 12 hrs., give about 30% of I, about 20% of *1-(3'-methoxy-4'-hydroxyphenyl)-2-methylcyclohexene*, analyzed as the *aryloxyacetic acid*, m. 73°, and about 30% of the polymer, b_{14} 180°. C. J. W.

Polymerization processes produced by pyridine. III. Intermediate products in the polymerization of *p*-quinone.

Otto Diels and Horst Preiss. *Ann.* **543**, 94–103(1939); cf. *C. A.* **32**, 9078[8].—D. and Kassebart (*C. A.* **31**, 5338[2]) have shown that *p*-O:C_6H_4:O (I) and C_5H_5N (II) yield 2,5-bis(*p*-hydroxyphenyl)-1,4-benzoquinone (IIA), in which it is assumed that N-contg. intermediates play an essential role. To test this hypothesis the reactions of I with II, α-picoline (III) and quinoline (IV) have been reinvestigated. I (5 g.) in 30 cc. $CHCl_3$ and 5.5 g. IV in 7.7 cc. 1:1 HCl, heated on the water bath, give 1.5 g. of *hydroquinonequinolinium chloride*, dark yellow, m. 274–5°. Hydroquinone-α-picolinium chloride (V) and satd. Na_2CO_3 give a dark red oil which, crystd. from luke-warm satd. Na_2CO_3, yields *hydroquinone-α-picolinium betaine* with 3 mols. H_2O, lost at 160–70°, giving the black-violet betaine, m. 217°; HCl regenerates V. I (20 g.) and 70 cc. II at 0°, allowed to warm to room temp., filtered from excess I and allowed to crystallize for 6 days at 25°, give 4 g. of ocher-yellow *2,5-bis(p-hydroxyphenoxy)hydroquinonepyridinium betaine* (VI), m. 217° (decompn.); concn. of the filtrate over H_2SO_4 *in vacuo* gives an addnl. 6.1 g. of impure VI. VI may be recrystd. with great loss from luke-warm II. Concn. of the II filtrate from VI on the water bath gives IIA and warming VI in II gives IIa, which also results on repeated crystn. of VI from MeCN; 1 crystn. from MeCN gives yellow to yellow-red intermediate products, m. 220–45°. Heating 3.3 g. of VI in 8 cc. HCO_2H and 3 cc. $PhNO_2$ gives 0.9 g. IIA. VI in Ac_2O-H_2SO_4, boiled several min., yields the di Ac deriv. (VII) of IIA. Crystn. of IIA from C_5H_5N gives a product with II of crystn., yellow, m. 250–3°. I (30 g.) and 120 cc. III at 0° give, after 14 days at room temp., 11 g. of the *α-picolinium analog* (VIII) of VI, with 1 mol. of III of crystn., yellow-brown, m. 187° (decompn.); concn. of the filtrate gives 8 g. of less pure VIII; repeated crystn. of VIII from MeCN yields IIA; crystn. of VIII from boiling III gives a IIA with 2 mols. of III of crystn., yellow, m. 245° (decompn.); acetylation of VIII gives VII. I and IV, shaken at room temp. and allowed to stand 4 weeks, give a mixt. of IIA and the IV salt of I; the relative yields of the 2 compds. vary greatly according to the conditions of the expts.; thus, 20 g. I and 105 cc. IV give in 8–10 weeks 18.4 g. of the salt and no IIA. Thymoquinone (180 g.) and 480 cc. II, allowed to stand at room temp. for 1–2 weeks, give 17 g. of a carmine-red *compd.*, $C_{16}H_{13}O_4N$, which gives a black mass at 205°; crystn. from MeCN gives deep carmine-red prisms, sinters 245°; the structure of this compd. is under investigation.

C. J. West

Hydroxyquinone. I. Synthesis of the dye of the polyporic acid series. Mitizō Asano and Yukio Kameda. *J. Pharm. Soc. Japan* **59**, 768–73(in German, 291–3)(1939).—Condensation of 9.3 g. aniline with 10.8 g. *p*-benzoquinone by the diazotization reaction gave 8 g. phenyl-*p*-benzoquinone (I), m. 113–14°. Condensation of 90 g. benzene and 9 g. I by the Friedel and Crafts reaction gave 2,5-diphenyl-*p*-benzoquinone, $C_{18}H_{12}O_2$, m. 212–13°. Condensation of 10.7 g. *p*-toluidine and 10.8 g. *p*-benzoquinone by the diazotization reaction gave 2-*p*-tolyl-*p*-benzoquinone (II), $C_{13}H_{10}O_2$, m. 137–9°, the other product being tri-*p*-tolylquinone, $C_{27}H_{22}O_2$, m. 197–9°. Condensation of 25 g. II with benzene by the Friedel and Crafts reaction gave 2-phenyl-5-*p*-tolyl-*p*-benzoquinone, $C_{19}H_{14}O_2$, m. 171–3°. Reduction of the above quinone with Zn dust gave 2-phenyl-5-*p*-tolylhydroquinone, $C_{19}H_{16}O_2$ (III), m. 151–3°. Oxidation of III with Br gave 2-phenyl-5-*p*-tolyl-3,6-dihydroxy-*p*-benzoquinone, $C_{19}H_{14}O_4$, m. 195–7°. Condensation of 11.5 g. *p*-anisidine with 10 g. *p*-benzoquinone by the diazotization reaction gave 1 g. *p*-anisylquinone (IV), m. 112–13°. Condensation of 120 g. benzene with 17 g. IV by the Friedel and Crafts reaction gave 5 g. (crude) 2-phenyl-5-*p*-anisyl-*p*-benzoquinone (V), $C_{19}H_{14}O_3$, m. 177–8° (recrystd. from EtOAc). Reduction of V in AcOH with Zn dust gave 2-phenyl-5-*p*-anisylhydroquinone, $C_{19}H_{16}O_3$, m. 157–8°; 2-phenyl-5-*p*-anisyl-3,6-bis(ethylamino)-*p*-benzoquinone, $C_{23}H_{24}O_3N_2$, m. 256°; 2-phenyl-5-*p*-anisyl-3,6-dihydroxy-*p*-benzoquinone, $C_{19}H_{14}O_5$, m. 261–3°.

F. I. Nakamura

Constituents of Ligusticum acutilobum. VIII. Constitution of byakangelicol. Takami Noguti and Minoru Kawanami. *J. Pharm. Soc., Japan* **59**, 755–7(1939).—The N salt of 5-methoxy-8-hydroxypsoralene and isoprene-HBr gave 5-methoxy-8-(γ,γ-dimethylallyloxy)-psoralene (I), $C_{16}H_{12}O_4OMe$, m. 105°, which depressed the m. p. of *byakangelicol* to 82°. I (0.2 g.) in 2 cc. $CHCl_3$ when treated with a 10% $CHCl_3$ soln. of BzO_2H for 5 days in a warm room gave *dl-byakangelicol* (II), $C_{16}H_{12}O_4OMe$, m. 106, which did not depress the m. p. of the natural product. II when boiled with alc. KOH gave *isobyakangelicolic* acid, m. 220°. II when boiled with a 1% oxalic acid soln. for 1 hr. gave *dl-byakangelicin*, $C_{17}H_{18}O_7 \cdot H_2O$, m. 116–17°.

F. I. Nakamura

Constitution and synthesis of conglomerone. F. N. Lahey and T. G. H. Jones. *Univ. Queensland Papers, Dept. Chem.* **1**, No. 12, 4 pp.(1939); cf. *Proc. Roy. Soc. Queensland* **50**, 10–13(1939); *C. A.* **33**, 3075[2].—Steam distn. of 760 lb. of leaves and terminal branchlets of *Eucalyptus conglomerata* yielded 870 cc. of oil which deposited 98 g. *conglomerone* (I), $C_{13}H_{16}O_4$, crystals from petr. ether, m. 62–2.5°; *2,4-dinitrophenylhydrazone* of I, m. 164°. Oxidation of I by CrO_3 gave dimethoxyquinone, m. 252°, identical with a sample prepd. by similar oxidation of 1,3,5-$C_6H_3(OMe)_3$ (II). Cold $KMnO_4$ soln. did not affect I, but, on heating, oxidation to $(CO_2H)_2$ resulted. Heating a mixt. of 15 g. I and 8 g. NaOH in 90% alc. for 4 hrs. at 160° gave a neutral product, b_2 130°, which was not identified; 1,3,5-$C_6H_3(OH)_3$ (III), which was identified by methylation to II, and iso-$PrCO_2H$. II, prepd. from III, MeOH and HCl followed by treatment with Me_2SO_4 and NaOH, was heated with iso-PrCOCl in CS_2 contg. $FeCl_3$ to give I, which was identical with the natural product; the 2,4-dinitrophenylhydrazones were likewise identical. I is therefore *1,2,4,6-iso-PrCOC$_6$H$_2$(OMe)$_3$*.

David E. Adelson

Ephedrine. III. Bis(α-hydroxy-β-methylaminopropyl)benzenes. Stanley D. Wilson and Chen-ta Chang. *J. Am. Chem. Soc.* **62**, 287–8(1940); cf. *C. A.* **29**, 758[1].—1,4-$C_6H_4(COEt)_2$ and Br in AcOH, heated on the water bath until the HBr is nearly expelled, give 95% of *1,4-bis(α-bromopropionyl)benzene* (I), m. 109–10°; 7 g. I in 200 cc. C_6H_6, added dropwise to 3 g. $MeNH_2$ in 200 cc. C_6H_6 and allowed to stand 100 hrs. at room temp., give 3 g. (62%) of *1,4-bis(α-methylaminopropionyl)-benzene-di-HCl* (II), decomps. above 320°; catalytic reduction of 2 g. in 95% EtOH(Pt) gives 1.8 g. of *1,4-bis-(α-hydroxy-β-methylaminopropyl)benzene-di-HCl* (III), m. 285–7°; the free base from this salt is difficult to purify; that from the reduction of the free ketone is a slightly brownish, somewhat gummy amorphous product, decompg. on heating; sulfate, decomps. above 320°; mandelate, m. 214°; tartrate, m. 167–8°. The 1,3-isomers of I, II and III were similarly prepd. and found to be oils. The free base is also amorphous and yields oily products with H_2SO_4, H_3PO_4 and $(CO_2H)_2$; the picrate is amorphous and decomps. on heating.

C. J. West

Some reactions of 2-diethylaminoethyl *p*-aminobenzoate (procaine). Elisa Ghigi. *Ann. chim. farm.* (Suppl. to *Farm. ital.*) Dec., 1939, 39–46.—At 100° in the presence of anhyd. NaOAc, without a solvent, procaine reacted slowly with 2,4-$(O_2N)_2C_6H_3Cl$ to form a new ester, *2-diethylaminoethyl 2',4'-dinitrodiphenylamine-4-carboxylate* (I), yellow plates from petr. ether, m. 85°. In boiling C_6H_6 as a solvent the reaction did not take place. When MeOH and EtOH were used as solvents in the reaction only the Me and Et esters of 2',4'-dinitrodiphenylamine-4-carboxylic acid (II) were formed, any I formed undergoing alcoholysis. The Me ester m. 163° and the Et ester m. 113°. Both were yellow needles. When Et_2NCH_2-CH_2OH (III) was used as a solvent some 2,4-dinitrophenol was formed. Treatment of I with 10% aq. NaOH gave III, 2,4-dinitrophenol and *p*-aminobenzoic acid. I with Na_2S in EtOH gave some II, m. 285–290°, and some 2'-amino-4'-nitrodiphenylamine-4-carboxylic acid (IV), m. 225° (decompn.). I with Na_2S in MeOH gave, among other products, the Me ester of IV, red needles, m. 218–19°.

L. E. Gilson

Synthesis of α-methyl-β-phenyl-β-methoxypropionic acid. Yuoh-Fong Chi, Chi-Chien Lueng and Wei-Yang Yu. *J. Chem. Eng. China* 5, 79–81(1938).—Ten g. $MeCHBzCO_2Et$ in 30 cc. AcOEt is catalytically hydrogenated at 80–90° in the presence of 0.3 g. Adams Pt oxide catalysts, giving after 4.5 hrs. Et α-methyl-β-phenyl-β-hydroxypropionate (I), an oil which solidifies on cooling, m. 120–1° (after recrystn. from petr. ether), $b_{5.4}$ 120–5°. One g. of I, refluxed for 1 hr. with 0.3 g. KOH in 10 cc. alc., gives the free acid (II), m. 116–18° after recrystn. from H_2O. II (35.5 g.) in dry ether is treated with 3.5 g. Na wire to form the Na salt. After removing the ether, this Na salt is dissolved in abs. alc. and heated with 26.4 g. MeI for 20 hrs., giving after purification and fractionation *in vacuo* 2 forms of Et α-methyl-β-phenyl-β-methoxypropionate (III), a liquid form b_{22} 104–6°, and a solid form m. 122–3° after recrystn. from petr. ether. The solid form of III (0.5 g.) is refluxed for 1 hr. with 0.15 g. KOH in 10 cc. alc., evapd. to dryness on a water bath, then redissolved in H_2O and acidified, yielding the β-form of α-methyl-β-phenyl-β-methoxypropionic acid (IV), m. 120.5–2.5° after recrystn. from H_2O. A similar hydrolysis of the liquid form of III yields the β-form of IV, m. 121–3° after recrystn. from H_2O. C. L. Tseng

Synthesis of 3,5-difluoro- and 3-fluoro-5-iodo-*dl*-tyrosine. James English, Jr., James F. Mead and Carl Niemann. *J. Am. Chem. Soc.* 62, 350–4(1940).—Through the diazonium fluoborate *o*-$MeOC_6H_4NH_2$ gives 30.8% of *o*-FC_6H_4OMe; this gives 40% of the 4-NO_2 deriv., which yields 75% of 2,4-$F(H_2N)C_6H_3OMe$; the diazo reaction with CuCN gives 46% of *2-fluoro-4-cyanoanisole*, $b_{1.5}$ 96–8°, m. 96.5°; $SnCl_2$-HCl gives 63% of 3,4-$F(MeO)C_6H_3CHO$ (I), $b_{4.5}$ 93°, m. 29–30°; this was also prepd. in 42% yield from *o*-FC_6H_4OMe with Zn-$(CN)_2$, $AlCl_3$ and HCN by heating 4 hrs. at 40–50°; I gives 95% of 4-(3′-fluoro-4′-methoxybenzylidene)-2-phenyloxazolo-5-one which, on reduction and hydrolysis, gives 49% (on basis of I) of 3-fluoro-*dl*-tyrosine, decomps. 275–8°; a soln. in 8 *N* NaOH with I-KI gives 47% of *3-fluoro-5-iodo-dl-tyrosine*, m. 192° (decompn.). *o*-FC_6H_4OMe (750 g.) in 2.4 l. CS_2, treated with cooling with 1.8 kg. $AlCl_3$ and 6.5 g. Ac_2O, gives 70–80% of *3-fluoro-4-methoxyacetophenone* (II), m. 92°; 90 g. I in 270 ml. H_2SO_4, treated at −10° with 22.5 ml. HNO_3 (d. 1.5) in 45 ml. concd. H_2SO_4, gives 44% of the *5-NO_2 deriv.* (III), b_4 144–7°; *phenylhydrazone*, m. 160–1° (decompn.). I gives 55% of the *5-NO_2 deriv.* (IV), m. 57–8° (*oxime*, m. 138–9°). Oxidation of II with $KMnO_4$ gives 70% of 3-fluoroanisic acid (V), m. 208–10°; the *5-NO_2 deriv.* m. 166° (57% yield); it also results in 62% yield from IV and in a poor yield by oxidation of III with $KMnO_4$ at 100°. V with MeOH and HCl gives 80% of *Me 3-fluoro-4-methoxy-5-nitrobenzoate*, b_3 128–31°, m. 50°; catalytic reduction with PtO_2 gives 90% of the *5-NH_2 deriv.*, m. 55°; through the diazonium fluoborate there results 28% of *3,5-difluoroanisic acid* (VA), m. 162°. Reduction of the acid chloride in xylene with Pd-$BaSO_4$ and quinoline S poison gives 3,5-difluoroanisaldehyde, which was not isolated but converted to *4-(3′,5′-difluoro-4′-methoxybenzylidene)-2-phenyl-5-oxazolone*, m. 165–9° (decompn.), in 52% yield; hydrolysis gives *α-N-benzoylamino-3,5-difluoro-4-methoxycinnamic acid*, m. 200–1°; refluxing with red P in III and Ac_2O for 5 hrs. gives 62% of *3,5-difluoro-dl-tyrosine*, m. 263–5° (decompn.); the over-all yield from *o*-$MeOC_6H_4NH_2$ is 0.73%. Reduction of 4 g. IV in 30 ml. EtOH with 50 mg. platinic oxide and 0.1 ml. of 0.1 *M* $FeCl_2$ under 3–4 atm. H for 30 min. gives 27% of *3-fluoro-4-methoxy-5-aminobenzyl alc.* (VI), b_2 141°, m. 55°. Reduction of IV with (iso-$PrO)_3Al$ in iso-PrOH gives 65% of 3-fluoro-4-methoxy-5-nitrobenzyl alc., b_3 155–9°, which is catalytically reduced in quant. yield to VI. The diazonium fluoborate could not be prepd. from VI. III is catalytically reduced to *3-fluoro-4-methoxy-5-aminoacetophenone*, $b_{2.5}$ 138°; *HCl salt*, decomps. 160–75°; this also did not form a diazonium fluoborate. Me 3,5-dinitroanisate gives a quant. yield of the diamine, m. 157°; this gives 55% of the cryst. tetrazonium fluoborate, which decomps. to give a quant. yield of VA. Passing H_2S into 75 g. picric acid in 14% NH_4OH gives 45% of *2,6-diamino-4-nitrophenol*, m. 169° (decompn.); di-Ac deriv., m. 235° (decompn.); CH_2N_2 gives 75% of the di-Ac deriv., m. 211°, of *2,6-diamino-4-nitroanisole*, m. 180–1°; the tetrazonium fluoborate is formed in 52% yield but decomps. explosively, giving a very small amt. of an oil. 2,4,6-$F(O_2N)(H_2N)C_6H_2OMe$ gives not more than 10% of *2,6-difluoro-4-nitroanisole*, m. 35°. C. J. West

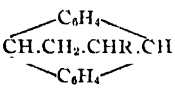
Alkaline cleavage of β-hydroxy-substituted acids. V. Acids having an alkyl radical in the α-position. D. Ivanov. *Ann. univ. Sofia. II. Faculté phys.-math.*, Livre 2, 35, 337–9(in French, 340)(1938–39); cf. *C. A.* 33, 8175[6]; 32, 3356[9].—$PhCH(OH)CHEtCO_2H$, $PhCH(OH)CMe_2CO_2H$, $Me_2CHCH(OH)CHMeCO_2H$, $MeCH(OH)CMe_2CO_2H$, $Me_2C(OH)CHMeCO_2H$, $Me_2C(OH)CMe_2CO_2H$, $Me_2C(OH)CHEtCO_2H$, $Pr_2C(OH)CMe_2CO_2H$ or their esters are not cleaved by heating with 15–20% aq. KOH. Results with β-HO-substituted acids may be summarized as follows: (1) those acids having an aryl radical in the α-position are cleaved irrespective of the nature of the radical or radicals in the β-position; (2) cleavage also takes place when both PhCH:CH- and $PhCH:CHCH_2$- radicals occur in the α-position; (3) with acids contg. 1 or 2 alkyl radicals in the α-position, only those which have 2 radicals, at least 1 of which is aryl or both are aryl-aliphatic, in the β-position are cleaved; and (4) acids with 1 or 2 radicals in the α-position and with an aryl radical or 1 or 2 alkyl radicals in the β-position are not decompd. George Ayers

Urea mandelate. Antonio Mossini. *Ann. chim. farm.* (Suppl. to *Farm. ital.*) Dec., 1939, 61–3.—One mol. urea unites with 1 mol. mandelic acid to form a stable cryst. compd., m. 93°, very sol. in water, EtOH and Me_2CO, slightly sol. in Et_2O, $CHCl_3$ and C_6H_6. Six g. taken orally renders human urine bactericidal provided the pH goes below 6. L. E. Gilson

Abnormal osmotic effects in chain molecules. II. Synthesis and cryoscopic behavior of polydepsides. Friedrich Klages, Fritz Kircher and Julius Fessler. *Ann.* 541, 17–53(1939); cf. *C. A.* 29, 7949[2].—*α-Trimethyl-β-diacetyldigalloyl chloride* (I), m. 166°, results in 37-g. yield from 40 g. acid and $SOCl_2$; *pentaacetyldigalloyl chloride* (IA), m. 173° (25 g. from 30 g. acid); *α-trimethyl-β,γ-tetraacetyltrigalloyl chloride* (II), m. 167° (18.5 g. from 25 g. acid). Diacetylgallic acid (III) (21.6 g.) and trimethylgalloyl chloride (IV) (18 g.) give 30 g. *α-trimethyl-β-diacetyldigallic acid*, m. 218°. III (10.9 g.) and 20 g. I give 15 g. of *α-trimethyl-β,γ-tetraacetyltrigallic acid*, m. 223–4°. III (6.7 g.) and 18.5 g. II give 8 g. of *α-trimethyl-β,γ,δ-hexaacetyltetragallic acid*, m. 235°. IV (10 g.) and 2.4 g. hydroquinone (V) give 3.5 g. *di(trimethylgalloyl)hydroquinone*, m. 224°. Triacetylgalloyl chloride (VI) (40 g.) and 14.5 g. V give 15 g. of *di(triacetylgalloyl)hydroquinone*, m. 250°. I (6 g.) and 0.7 g. V give 2.5 g. of *di(α-trimethyl-β-diacetyldigalloyl)hydroquinone*, m. 248°. VI (30 g.) and 5.5 g. phloroglucinol (VII) give 6 g. *tri(trimethylgalloyl)-phloroglucinol*, m. 180°. VI (29 g.) and 3.9 g. VII give 15 g. of *tri(triacetylgalloyl)phloroglucinol*, m. 210°. I (20 g.) and 1.8 g. VII give 5 g. of *tri(α-trimethyl-β-diacetyldigalloyl)phloroglucinol*, m. 150–75°. IA (27.8 g.) and 2.12 g. VII give 5 g. of *tri(pentaacetyldigalloyl)phloroglucinol*, m. 150–75°. Mol. wts. are given for these compds. in dioxane and AcOH and for some of them in $CHBr_3$. A lengthy discussion of the abnormal results is given and correlated with the work of Hess, Meyer and Staudinger. C. J. West

Synthesis of coumarins from *o*-hydroxyaryl alkyl ketones. II. Formation of *o*-coumaric acids from *o*-hydroxyaldehydes. Duhkhaharan Chakravarti and Brajeswar Majumdar. *J. Indian Chem. Soc.* 16, 389–92 (1939); cf. *C. A.* 32, 7026[9]; 33, 5494.—The Me ethers of the *o*-HO aldehydes condense with EtO_2CCH_2Br (I) and $EtO_2CCHBrMe$ (II) to form *trans*-cinnamic esters, which do not yield coumarins on heating with HI or on standing with cold H_2SO_4 as do the esters obtained from *o*-hydroxyaryl alkyl ketones. A mixt. of 11 g. *o*-$MeOC_6H_4CHO$ in

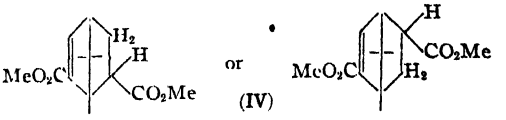
50 cc. anhyd. benzene, 6 g. Zn wool and 16 g. I was heated at 100° for 2 hrs. and poured into ice-cold dil. H_2SO_4. The washed and dried benzene layer was evapd. down and distd., yielding 11 g. of *o*-$MeOC_6H_4CH(OH)CH_2CO_2Et$, b_{10} 150–4°, which was converted by heating with 6 g. $SOCl_2$ and 9 g. pyridine in ether into 10 g. *Et 2-methoxy-trans-cinnamate*, $C_{12}H_{14}O_3$, b_8 150°, hydrolyzed to 2-methoxy-*trans*-cinnamic acid, m. 182°, identical with a specimen prepd. from *o*-coumaric acid by methylation with Me_2SO_4 and hydrolysis. Similarly, *o*-$MeOC_6H_4CHO$ was converted by Reformatskiĭ's reaction with Zn and II to *o*-$MeC_6H_4CH(OH)CHMeCO_2Et$, b_4 155°, transformed by $SOCl_2$ in the presence of pyridine to *Et 2-methoxy-α-methyl-trans-cinnamate*, $C_{13}H_{16}O_3$, b_4 150–5°, hydrolyzed by alc. KOH to the corresponding acid, m. 102°. Condensation of 2,4-$(MeO)_2C_6H_3CHO$ with I gave 2,4-$(MeO)_2C_6H_3CH(OH)CH_2CO_2Et$, b_8 180–4°, dehydrated to the *cinnamic ester*, b_8 180–4°, hydrolyzed to 2,4-dimethoxy-*trans*-cinnamic acid, m. 184°. To study the influence of a Ph substituent on the formation of *trans*-cinnamic esters, 8.5 g. of 5,2-Cl(MeO)C_6H_3CHO was condensed with 8.5 g. I to the propionate (8 g.) which, on dehydration with $SOCl_2$, gave 6 g. of *Et 2-methoxy-5-chloro-trans-cinnamate*, $C_{12}H_{13}ClO_3$, b_8 170°, hydrolyzed to the corresponding acid (III), m. 191°. A sample of authentic III was prepd. by treating 6-chlorocoumarin with HgO, methylating and hydrolyzing with alc. KOH. Thus it is shown that if there are no β-alkyl groups in the resulting cinnamic ester, the latter has the trans configuration. Otherwise the esters have the cis configuration and readily form coumarins. The 2-MeO aldehydes are useful starting materials for the prepn. of *o*-coumaric acid derivs. in satisfactory yields. Condensation of 10 g. of 2,4-$(MeO)_2C_6H_3Ac$ (IV) with 9 g. II and distn. of the product yielded 8.5 g. of *Et 2,4-dimethoxy-α,β-dimethyl-cinnamate* (V), b_8 180–2°, converted by standing overnight in cold H_2SO_4 (d. 1.84) to 3,4-dimethyl-7-methoxycoumarin, m. 140°. Heating V (1 g.) with 7 cc. HI (d. 1.7) at 140° for 2 hrs. gave colorless needles of 3,4-dimethyl-7-hydroxycoumarin, m. 256°, on recrystn. from alc. Similarly, condensation of 10 g. IV with I gave an unsatd. ester, b_6 174°, on vacuum distn. No ring closure was effected by heating with HI or on treatment with cold H_2SO_4. Hydrolysis gave the known 2,4-dimethoxy-β-methylcinnamic acid, m. 145°. C. R. Addinall



Hydrogenation of coumarin and related compounds. Peter L. De Benneville and Ralph Connor. *J. Am. Chem. Soc.* 62, 283–7(1940).—Coumarin (I) has been reduced under a variety of conditions, using a H pressure of 100–200 atm. Over Ni (in EtOH for 8 hrs. at 200°) there results 32% octahydrocoumarin (II), 31% *hexahydrochroman* (III), 7% Et β-cyclohexylpropionic acid (IV) and 27% of a polymer (V); at 250° for 4 hrs. the yields were 41% II, 27% III, 13% IV and 6% V; in methylcyclohexane (VI) (3 hrs. at 205°) there results 53% II, 13% III and 10% V; at 250° for 0.3 hr., 58% II, 9% III and 11% V; at 250° for 13.5 hrs., 19% II, 35% III and 27% V; in Et_2O (0.5 hr. at 100°) there is formed 90% of dihydrocoumarin (VII); with Cu chromite (VIII) (in EtOH for 0.7 hr. at 250°) there is formed 90% of γ-(*o*-hydroxyhenyl)propyl alc. (IX); without a solvent 0.7 mole I and 10 g. VIII at 250° for 1.5 hrs. give 83% IX; with Ni in VI (6 hrs. at 250°) there results from II 57% III; II in VI with VIII (4.5 hrs. at 250°) gives 50% γ-(*o*-hydroxycyclohexyl)propyl alc. (X) and 11% of γ-cyclohexylpropyl alc. (XI); IX in Et_2O with Ni (2 hrs. at 240°) gives 40% III and 37% X; chroman in EtOH with Ni (6 hrs. at 250°) gives 41% III; $Ph(CH_2)_3OH$ in EtOH with Ni (2 hrs. at 220°) gives 86% XI. Over VIII the formation of VII was shown by the pressure drop at 140–60°. V is a thick, slow-flowing non-distillable material remaining as a residue after the distn. The following phys. consts. are reported. II, b_{15} 144–6°, n_D^{25} 1.4970, d_4^{24} 1.0999; III, b_{760} 186–7°, n_D^{25} 1.4714, d_4^{25} 0.9536; IX, b_8 159–61° (benzoate, m. 98.5–9.5°); X, b_{25} 185–6°, n_D^{25} 1.4867, d_4^{25} 1.0294; IV, b_{17} 105–13°, n_D^{25} 1.4480; XI b_{10} 105–6° (α-naphthylurethan, m. 82–3°). Chroman, b_{760} 110–14°, n_D^{25} 1.5462, d_4^{25} 1.0575, was prepd. in 87% yield by reacting IX with PBr_3 (added during 0.5 hr. with cooling, stirring an addnl. 2 hrs., allowing to stand overnight and refluxing 0.5 hr.), decompg. with aq. NaOH, refluxing for 3 hrs., extg. with C_6H_6 and distg.; omission of the alkali treatment decreases the yield to 70–5%. The mechanism of the reduction of I is discussed. C. J. West

Walden rearrangement. IV. Method of reaction with phosphorus pentachloride. Walter Hückel and Hubertus Pietrzok. *Ann.* 540, 250–74(1939); cf. *C. A.* 33, 3359[1].—*l*-Menthol (I) (40 g.) with 60 g. com. PCl_5 in petr. ether gives 36.6 g. of a menthyl chloride (II) with $[\alpha]_D$ between −25 and −30°; a pure PCl_5 gives 84% of a II with $[\alpha]_D$ −9.1 to −12.5°; similar results were obtained with Et_2O, CCl_4 and $CHCl_3$, showing that the solvent has little effect on the reaction. The difference in behavior of the com. and the pure PCl_5 is due to impurities, of which $FeCl_3$ is the most likely. A mixt. of 1 mol. PCl_5 and 1 mol. $FeCl_3$ gives a II with $[\alpha]_D$ −37.3° or nearly pure 1[c]-methyl-3[c]-chloro-4[t]-isopropylcyclohexane; 1/15 mol. $FeCl_3$ gives as the principal product a II with $[\alpha]_D$ −27.75° and a little with −36.65°; $FeCl_3$ with H_2O of crystn. was not effective. $AlCl_3$ produced about the same results as $FeCl_3$. The $[\alpha]_D$ of a mixt. of II and *d*-neomenthyl chloride (III) is not changed by the action of $AlCl_3$ or $FeCl_3$ at room temp. or in the presence of PCl_5 at 0°; thus their action is not due to the change of III into II. Pure PCl_5 (68 g.) in 50 cc. petr. ether and 50 g. I in 110 cc. C_5H_5N, mixed at 0° during 0.5 hr. and stirred for an addnl. 0.5 hr., give 2.3 g. nearly pure III, $b_{0.06}$ 40–1°, $[\alpha]_D$ 42.21°, d_4^{20} 0.9457, n_D^{25} 1.46403; the principal part of the I is changed to esters of H_3PO_4 and Cl derivs. of these esters. The difference in the action of PCl_5 in C_5H_5N or in the presence of $FeCl_3$ or $AlCl_3$ is explained on the basis of the formation of complexes such as $[PCl_4]^+$ $[FeCl_4]^-$ or $[C_5H_5N{:}PCl_4]^+Cl^-$. I and concd. HCl, heated at 100°, give a product with $[\alpha]_D$ −26.2°, consisting of about 75% II and 25% III; passing HCl into a molten I and $ZnCl_2$ at 100° gives a II with $[\alpha]_D$ −13.5°; without $ZnCl_2$ there is no reaction; there is also no reaction between I and HCl in ether or C_6H_6 at room temp. for 8 weeks. II, $[\alpha]_D$ 25.12° (50 g.), and 60 g. $PhNH_2$, heated 4 hrs. at 160–70°, give 32.7 g. of menthene (IV) and 2.5 g. of II with $[\alpha]_D$ −45.4°; 240 g. of II with $[\alpha]_D$ −33.5° and 180 g. quinoline, heated 5.5 hrs. at 190–200° give 72.1 g. IV and 11.5 g. of a II with $[\alpha]_D$ −45.9°; in another expt. 40 g. of a II with $[\alpha]_D$ −26.2° and 30 g. quinoline give 6.3 g. IV and 17 g. of a II with $[\alpha]_D$ −45.4°. Thus quinoline is much more suitable for the prepn. of a pure *l*-II. II with $[\alpha]_D$ −25.85° is unchanged after shaking 3 days with 30% KOH, even with the addn. of dioxane to increase the soly. Distn. of the IV from II and $PhNH_2$ gives a IV with $[\alpha]_D$ 19.85°; treatment with *p*-$MeC_6H_4SO_3H$ in EtOH gives $[\alpha]_D$ 17.68°, indicating 18% of *trans*-2-menthene (V); the remaining IV is completely racemized 3-menthene. The IV from II and quinoline contains 15% V, 25% active and 60% of racemized 3-menthene. I (31 g.) and 87 g. pure PBr_3 in 200 cc. petr. ether (cooling) give 25 g. of menthyl bromide (VI), $b_{0.0005}$ 41°, $[\alpha]_D$ 8.87°, d_4^{20} 1.1599, n_D^{25} 1.48481; another expt. gave a product with $[\alpha]_D$ −5.98° and a 3rd with $[\alpha]_D$ −4.58°; the residue of the distn. is a *dibromomenthene*, $b_{0.05}$ 80°. I and PBr_3 with $AlBr_3$ give a VI, $b_{0.05}$ 44–6°, $[\alpha]_D$ −24.16°, d_4^{20} 1.1600, n_D^{25} 1.48549. *l*-Borneol (VII) ($[\alpha]_D$ −36.99°) with PCl_5 gives a chloride (VIII) m. 140–2°, $[\alpha]_D$ 4.8° (EtOH); PCl_5 (27 g.) and 3 g. $FeCl_3$ give a VIII m. 162°, $[\alpha]_D$ 4.3° (EtOH); the Cl removed with EtOH-KOH is 81 and 97.8%, resp.; thus the latter is nearly pure isobornyl chloride (IX). That the reaction proceeds through the intermediate formation of camphene hydrochloride (X) is shown by working in ether. Thus 15 g. VII and 22 g. PCl_5 in 15 cc. petr. ether and 15 cc. ether give a product with $[\alpha]_D$ 35.1°; the ratio of X to IX is about 2:1; with $FeCl_3$ the product in ether has $[\alpha]_D$ 8°; the ratio of X to IX is about 1 to 3. C. J. West

Optically pure *l*-α-phellandrene. N. C. Hancox and T. G. H. Jones. *Univ. Queensland Papers, Dept. Chem.* 1, No. 14, 4 pp.(1939); cf. *Proc. Roy. Soc. Qneensland* 50, 14–20(1939).—*l*-α-Phellandrene (I) was exhaustively



fractionated at 1–2 mm. to yield I of d_{20} 0.8324, n_D^{20} 1.4724, $[\alpha]_D^{20}$ −177.4°, diene no. (cf. *C. A.* **31**, 4837[6], 4839[2]) 186.3 (calcd. 186.6). The results indicated that I was 99.5–100% pure. The relation between $[\alpha]_D^{20}$ and I content of a sample as detd. by the diene no. is linear. *Eucalyptus dives* oil was found to contain 18.8% I. D. E. A. 1

Diene syntheses. XI. Diene syntheses with vinyl esters and halogenated ethylenes. Simple methods in the norcamphor series. Kurt Alder and Hans Ferdinand Rickert. *Ann.* **543**, 1–27(1939); cf. *C. A.* **33**, 1299[1]; **34**, 729[2].—Cyclopentadiene (I) and an excess of vinyl acetate (II), heated 10 hrs. at 185–90°, give 72 g. unchanged II and 3 fractions, b_{14} 73–7° (100 g.), 77–140° (10 g.) and 140–5° (48 g.). The 1st fraction is dehydronorbornyl acetate (III); catalytic reduction and hydrolysis gives α-norborneol (IV), m. 149–50° (phenylurethan, m. 159–60°; *acid phthalate*, m. 109–10° (*β-isomer*, m. 80–1°); *3,5-dinitrobenzoate* (V), pale yellow, m. 123° (*β-isomer*, m. 105°); the *compds.* of V with α-$C_{10}H_7NH_2$ m. 139–40° (α) and 126° (β)). Oxidation of IV gives norcamphor, m. 92°. Hydrolysis of III with MeOH-KOH gives *dehydro-α-norborneol* (VI), m. 108–9°; PhN_3 gives the *hydrotriazole*, $C_{15}H_{17}ON_3$, m. 147–8°; catalytic reduction gives IV. Oxidation of VI with $K_2Cr_2O_7$ in AcOH-H_2SO_4 for 0.5–1 hr. gives *dehydronorcamphor*, which solidifies between 0 and 2°; *semicarbazone*, m. 207–8°; *hydrotriazole*, $C_{13}H_{18}ON_3$, m. 140–1°. The 3rd fraction consists principally of the acetate of 1,4,5,8-bisendomethylene-Δ⁶-β-octalol (VII); catalytic reduction gives the dihydro deriv. (b_{12} 147–9°) which is sapond. to *1,4,5,8-bisendomethylene-β-decalol* (VIII), m. 90–2°; *phenylurethan*, m. 118° and 120–1°, sepd. by crystn. from ligroin. Oxidation of VIII gives the corresponding β-deculone, m. 207–8°. Addn. of I to vinyl formate (heating 14 hrs. at 180–90°) gives the formate of VI, b_{20} 80°, and the formate of VII, b_{20} 130–40°; hydrolysis and sapon. give VIII. Butadiene (IX) (100 g.) and 100 g. II (heated 12 hrs. at 180°) give 8–10 g. of 3-cyclohexen-1-ol acetate; the principal product is the dimer of IX. 2,3-Dimethylbutadiene and II, as above, give the acetate of 3,4-dimethyl-3-cyclohexen-1-ol, whose *phenylurethan* m. 112°. 1,3-Cyclohexadiene and II give the acetate of 2,5-endoethylene-3-cyclohexen-1-ol; the free alc. yields a *phenylurethan*, m. 125°. Anthracene and II in xylene, heated 14 hrs. at 220–30°, give 6 g. of the *adduct* 2

(X, R = OCOMe) m. 100–1°; the *alc.* m. 140–2°. I (80 g.) and 80 g. vinyl chloride, heated 15 hrs. at 170–80°, give 73 g. b_{12} 46–7° and 28 g. b_{12} 128–33°; the 1st fraction is *dehydronorbornyl chloride* (XI); this yields a *hydrotriazole*, $C_{13}H_{14}N_3Cl$, m. 113–16°; catalytic reduction gives norbornyl chloride, b_{11} 50–2°; EtMgBr, followed by CO_2, gives 2,5-endomethylenehexahydrobenzoic acid, b_{12} 128–30°. XI was also transformed into norbornylane and norbornylene. The 2nd fraction is *1,4,5,8-bisendomethylene-Δ⁶-β-chlorooctalin*, which yields a hydrotriazole, $C_{15}H_{20}N_3Cl$, m. 195°. I (125 g.) and 175 g. ClCH:CHCl, heated 15 hrs. at 180–90°, give 60 g. b. 70–6°, 15 g. b. 76–140° and 58 g. b. 140–50°; the *hydrotriazole* of the 1st fraction, $C_{13}H_{13}N_3Cl_2$, decomps. 148° and that of fraction 2, $C_{18}H_{19}N_3Cl_2$, m. 210° (decompn.). Cl_2C:CHCl and I give an oil, b_{11} 158–60°, which yields a *hydrotriazole*, $C_{14}H_{18}N_3Cl_3$, m. 225–6°. 3

XII. Syntheses in the camphor and epicamphor groups by the diene method. Diene syntheses of 1,5,5-trimethyl-1,3-cyclopentadiene and β-camphylic acid with vinyl acetate. Kurt Alder and Erwin Windemuth. *Ibid.* 41–56.—Vinyl acetate (I) (15 g.) and 12 g. of 1,5,5-trimethyl-1,3-cyclopentadiene, heated 20 hrs. at 235–40°, give 88% of a mixt. of dehydrobornyl acetate and dehydroepibornyl acetate, b_{12} 92–4°. Catalytic reduction gives a mixt. of the acetates, b_{12} 98–101°, of borneol and epiborneol, m. 183–4°; crystn. of the 3,5-dinitrobenzoates from MeCN and MeOH gives 31.6% of the *dl*-bornyl ester (II) and 41.8% of *dl*-epibornyl ester (III), with 26.6% of intermediate fractions. Hydrolysis of II and oxidation give *dl*-camphor; III gives *dl*-epicamphor. The trimethylcyclopentadiene (C_8H_{12}) of Damsky (*Ber.* **20**, 2966(1887)) and I, heated 12 hrs. at 170–80°, give an oil, b. 203–12°; hydrogenation and hydrolysis give an *alc.*, $C_{10}H_{18}O$, m. 98–9° (*phenylurethan*, m. 111–12°); oxidation with $K_2Cr_2O_7$ in AcOH-H_2SO_4 gives a ketone, whose *semicarbazone* m. 222°. Addn. of I to Me β-camphylate (heating 14 hrs. at 230°) gives 84.2% of the *adduct* (IV), 4

b_{12} 142–6°; esterification and oxidation give a ketone, whose *semicarbazone*, $C_{13}H_{19}O_3N_3$, m. 230° (decompn.); heating with EtONa in EtOH for 20 hrs. at 200–5° gives bornylene-2-carboxylic acid, which is oxidized to *dl*-camphoric acid, m. 203°. Hydrolysis of IV gives the *HO lactone*, $C_{11}H_{16}O_3$, m. 206°; *phenylurethan*, m. 177°; careful oxidation with CrO_3 in AcOH gives a ketone, whose *semicarbazone* m. 237°; less careful control of the oxidation gives a HO acid, $C_{11}H_{17}O_3$, m. 159°. 5

XIII. Diene syntheses of 1,5,5-trimethyl-1,3-cyclopentadiene, α- and β-camphylic acids with maleic anhydride and acetylenedicarboxylic acid. (Steric course of addition and substitution reactions. 10.) *Ibid.* 56–78.—1,5,5-Trimethyl-1,3-cyclopentadiene (I) and maleic anhydride (II) in Et_2O give *3,6-endomethylene-3,7,7-trimethyl-Δ⁴-tetrahydrophthalic anhydride* (III), m. 137°; soln. in Na_2CO_3 and pptn. with dil. H_2SO_4 give the free *acid* (IV), m. 173° (decompn.). Addn. of Br to the Na_2CO_3 soln. of IV gives the *bromolactonemonocarboxylic acid*, m. 215°; *Me ester*, m. 130°. III and PhN_3 in AcOEt do not form an addn. product after standing 3 months. Catalytic reduction of IV in AcOH with PtO_2 gives *cis-3,6-endomethylene-3,7,7-trimethylhexahydrophthalic acid* (V), m. 175° (decompn.); *anhydride*, m. 171°; heating V with MeONa in MeOH for 2.5 hrs. gives the trans acid, m. 236–7°. I (5.3 g.) and 10 g. $(CCO_2Me)_2$ in 3 cc. Et_2O give 9 g. of *Me 3,6-endomethylene-3,7,7-trimethyl-Δ¹,⁴-dihydrophthalate* (VI), b_{12} 142–3°; partial catalytic reduction yields the *Δ¹-tetrahydro deriv.*, b_{12} 143–4°; the free *acid* (VII) m. 172°; *anhydride*, m. 115–16°. Oxidation of VII with 43% HNO_3 (8 hrs. at 120–30°) gives *dl*-camphoric acid, m. 203°. I and $(CCO_2H)_2$ in Et_2O, heated 12 hrs. at 120–30°, give the free acid (VIII) corresponding to VI; partial reduction gives VII. Damsky's hydrocarbon (C_8H_{12}) and II in Et_2O give an *isomer* (X) of III, m. 95–6°; the free *acid* m. 158–9°; the *bromolactonemonocarboxylic acid* m. 193–4°; its *Me ester* m. 133–4°; catalytic reduction of X gives the *isomer* (XI) of V, m. 185–6°; oxidation with $KMnO_4$ gives the *compd.* $C_{12}H_{14}O_5$, m. 235–6°. IX and $(CCO_2H)_2$ give an *isomer* (XII) of VIII, m. 175–6°; catalytic reduction gives the isomer (XIII) of VII, m. 178–9°; further reduction of the acid gives X which with AcCl yields XI. IX and $(CCO_2Et)_2$, heated 1 hr. at 260–80°, give the *di-Et ester* of XII, b_{20} 174–5°; reduction yields the *di-Et ester* of the Δ¹-acid, b_{17} 182–3°; hydrolysis gives XIII, whose *anhydride* m. 61–2°. Me α-camphylate (XIV) and II in C_6H_6, refluxed 6 hrs., give *endo-cis-3,6-endomethylene-3,7,7-trimethyl-6-carbomethoxy-Δ⁴-tetrahydrophthalic anhydride* (XV), m. 115°; the free *acid* m. 195°; the *bromolactonemonocarboxylic acid* m. 185° (*Me ester*, m. 172°); catalytic reduction of XV gives the *hexahydro deriv.*, m. 94–5°. XIV (4.5 g.) and 5 g. $(CCO_2Me)_2$ in Et_2O, heated 10 hrs. at 110–15°, give 7.8 g. of the *tri-Me ester*, $C_{16}H_{20}O_6$, b_3 162–5°, m. 72°; partial reduction gives a Δ¹-compd., partially sapond. by 20% MeOH-KOH to a *mono-Me ester*, m. 204°. XIV and $(CCO_2H)_2$, heated 12 hrs. at 100° and reduced with Pd, give the Δ¹-acid, $C_{14}H_{18}O_6$, m. 210°; *anhydride*, m. 119°. The β-isomer of XIV and II, heated in C_6H_6 for 8 hrs. at 120°, give the *4-carbomethoxy isomer* of XV, m. 132–3°; the free *acid* m. 165°; *bromolactonemonocarboxylic acid*, m. 230°. 6

C. J. West

Cyclopentadiene series. II. α- and β-Camphylic acids and their decarboxylation products. 1,5,5-Trimethyl-1,3-cyclopentadiene. Kurt Alder and Erwin Windemuth. *Ann.* **543**, 28–40(1939); cf. *C. A.* **30**, 8177⁴.—Sulfocamphylic acid (Kachler, *Ann.* **169**, 179(1873)) (50 g.) and 130–50 g. solid KOH, heated at 210–15°, the melt dissolved in H_2O, acidified with concd. HCl, extd. with Et_2O and the oil crystd. from AcOH, give di-β-camphylic acid (I) and not the α-isomer as Perkin supposed (*J. Chem. Soc.* **1903**, 862). Distn. of the AcOH residues at 130–40°/12 mm. gives β-camphylic acid (II), m. 106°; distn. at 170–200° gives some of the α-isomer (III); thus, III is a transformation product of II. Distn. of I at atm. pressure gives III as the only product. The *di-Me ester* of I m. 64°; depolymerization at 350 mm. and 220–30° gives the Me ester of II. Distn. of the Ca salt of II or III according to Damsky (*Ber.* **20**, 2966(1887)) gives his hydrocarbon, b. 133–5°. Decarboxylation of II or III with Cu chromite in quinoline gives 73% of 1,5,5-trimethyl-1,3-cyclopentadiene, b. 99–105°. In the distn. of the Ca salt a wandering of the Me group occurs. C. J. West

Reduction of tagetone to tagetol. T. G. H. Jones. *Univ. Queensland Papers, Dept. Chem.* **1**, No. 11, 2 pp. (1939); cf. *C. A.* **29**, 4339⁸.—By refluxing 50 g. tagetone with a soln. of 50 g. Al in 1 l. iso-PrOH, 30 cc. of *tagetol* (I), $C_{10}H_{18}O$, b_3 55°, $d_{15.5}$ 0.8766, n_D^{19} 1.4760, was obtained; *Ac deriv.* of I, b_3 65°, $d_{15.5}$ 0.9154. Attempts to dehydrate I in petr. ether by $KHSO_4$ or P_2O_5 were unsuccessful, probably owing to the instability of the desired terpene. I reacted readily with $C_{10}H_7NCO$ and PhNCO, but no cryst. derivs. could be obtained. D. E. A.

Preparation of synthetic borneol by the acetic acid method. Minoru Imoto. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 314(1939); cf. *C. A.* **33**, 7766³; **34**, 744⁴.—The pinenecamphene fraction (136 g., contg. 46.7% camphene by the Bertram-Walbaum hydration method) from abies oil was stirred at 110–120° with 120 g. com. 99% AcOH in the presence of 20 g. Ac_2O and 1.9 g. B_2O_3. After 15 hrs. the ester content was 58.6%; after subsequent addn. of 20 g. 60% H_2SO_4 and heating for 7 hrs. at 50–60°, the yield of ester was 68.5%. From 131 g. of the reaction mixt., treated as described in previous reports, there were obtained (1) 60 g. crude borneol, m. 189–93°, $[\alpha]_D$ ±0° (in alc.), and contg. 56.1% isoborneol (Hesse's method), (2) 2 g. of a liquid alc., and (3) 42 g. of a terpene fraction with an ester content of 30.3%. White camphor oil may be used similarly for the prepn. of isoborneol. George Ayers

The products of autoxidation of several terpenes. R. Dupont. *Ind. chim. belge* **11**, 3–13(1940); cf. *C. A.* **34**, 4033.—Autoxidation of 250 g. citronellol (I) at 75° for 11 days in the app. (2.9 l. capacity) of Chavanne and Miller (*C. A.* **24**, 5027), absorbed 16 l. of O and gave a gaseous fraction contg. 25% CO_2, 8% CO and 27% H_2 and a liquid fraction (neutral, after extg. a small amt. of acids) consisting of unreacted I, I oxide and dihydroxycitronellol, the last 2 being identified by oxidation with $K_2Cr_2O_7$ to Me_2CO and β-methyladipic acid. Similarly, by autoxidation 165 g. camphene (II) at 70° for 16 days absorbed 8.5 l. of O, giving, after sepg. small amts. of acidic products, unreacted II, camphenilone, and a *compd.* $C_{10}H_{16}O_2$, b_{13} 142–5°, probably an unsatd. peroxide which decomps. upon redistn. Autoxidation of 160 g. cedrene (III) at 75° for 7 days absorbed 11.5 l. of O, giving a gaseous mixt. contg. 25.6% CO_2, 5.5% CO and 21.4% H_2O, and a liquid fraction (neutral) consisting of unreacted III, cedrone and its corresponding secondary alcohol. Autoxidation of 136 g. α-terpineol (IV) at 85° for 10 days absorbed 13 l. of O, giving a gaseous mixt. contg. 6.6% CO_2, 2.0% CO and 13.6% H_2, and, after sepg. small amts. of acids, a liquid fraction consisting of unreacted IV and inactive hydroxycarvone, which was also obtained by oxidizing IV with SeO_2. Autoxidation of 150 g. dihydrocarveol (V) in the presence of cobaltous acetylacetonate at 85° for 10 days absorbed 10 l. of O was accompanied by darkening and formation of H_2O, yielding unchanged V and tetrahydro-*p*-tolyl Me ketone (semicarbazone, m. 172°), which was oxidized to *p*-MeC_6H_4COMe and is assumed to have the double bond in the 1,2-position. Autoxidation of 127 and 160 g. of limonene at 65° for 9 days absorbed 18 and 22 l. of O, resp., giving a gaseous mixt. contg. 19.0% CO_2, 6.0% CO and 42.5% H_2, and a liquid fraction, after removal of small amts. of acids, consisting of carveol, carvone and *trans*-8-*p*-menthene-1,2-diol, m. 67–8°, $[\alpha]_D^{19}$ 39.0° ± 1.6°. Autoxidation of 1 g.-mol. wt. of α-phellandrene at 70° for 5 days absorbed 14.5 l. of O, giving a gaseous fraction contg. 18% CO_2, 6.5% CO and 53% H and a liquid mixt. consisting of *p*-cymene, an alc. oxide corresponding to $C_{10}H_{16}O_2$, which oxidizes to thymoquinone, and α-phellandrene glycol, likewise identified by oxidation with Bechmann's CrO_3 mixt. to a keto lactone of Henry and Paget (*C. A.* **22**, 1346) and thymoquinone. The above results agree with those obtained by others to which numerous references are given and it is concluded that, in regard to the action of mol. O, ethylenic hydrocarbons contain 2 points of attack, viz., the double bond and the Me group in the α-position to the double bond. J. F. L.

Asymmetrical catalysis. Asymmetry introduced by means of Grignard's reagent. Mario Betti and Elio Lucchi. *Boll. sci. facoltà chim. ind., Bologna* **1940**, No. 1–2, 2–5; cf. *C. A.* **33**, 7273¹.—The synthesis of compds. contg. an asym. C atom by means of Grignard's reagent is described. Dimethylbornylamine (I) is prepd. in satisfactory yields by heating for 5 hrs. at 220–30° HCO_2NH_4 with camphor in a sealed tube, using small amts. of the reagents, and treating the bornylamine formed with alc. MeI in the presence of NaOH. The reaction product from 12 g. I, 1.60 g. dry Mg filings and 9.45 g. MeI on condensation with BzH in dry benzene and subsequent hydrolysis with dil. HCl gives 6 g. PhCH(OH)Me, b. 205°, which is optically active, 0.30°, and after 24 hrs. 0.18°. The same compd. is obtained by condensing the reaction product from PhBr, Mg and I with AcH. The optical rotation of this compd. is 1.33°, and 0.33° after 24 hrs. Dora Stern

Crystal chemistry of camphor derivatives. I. Formation of mixed crystals or molecular compounds in the binary systems of several oxo derivatives of camphor. Atusi Watanabe. *Proc. Imp. Acad.* (Tokyo) **10**, 349–52(1939) (in German).—X-ray examn. of various camphor derivs. gave the following data for the double refraction, crystal system and *n*(D line): *o*-oxocamphor (I), biaxial, neg., rhombic, 1.52_0 (β), 1.57_5 (γ), needles; *p*-oxocamphor (II) uniaxial, neg., trigonal, 1.50_0, 1.50_3, plates; 6-oxocamphor (III), none, cubical, 1.50_5; *trans*-π-oxocamphor (IV), none, cubical, 1.49_6; α-10-oxocamphor (V), uniaxial, neg., trigonal, 1.50_0, 1.50_3; β-isomer, none, cubical, 1.49_6. The system IV–II forms 3 series of mixed crystals: up to 15% IV, isomorphic with II, from 15 to 25%, dimorphic, which are isomorphic with IV or II; from 25–100%, isomorphic with IV. These mixed crystals are more stable than IV and are not oxidized on standing several days at room temp., whereas IV is largely oxidized to isoketopinic acid in this time. The soln. of IV–V in Et_2O (15–40% IV) gives mixed crystals isomorphic with II, which on heating at 100° change to a 1:2 mol. compd. similar in crystal form to III; the mixed crystals from solns. contg. 50–100% IV are isomorphic with IV; the crystals from 20–40% IV are far more stable than either component. With the system IV–III, the mixed crystals from 0–70% IV are isomorphic with III; the mixt. from 60–80% IV in ether is similar to II, indicating a mol. compd., which changes to mixed crystals on heating. The system IV–I gives a 1:1 mol. compd. similar to the crystal form of II. The mixed crystals from the system V–III in Et_2O are isomorphic with II; on heating over 100° these form crystals isomorphic with IV; these mixed crystals are stable for weeks at room temp., whereas IV is largely oxidized in 1 week at 25°. The crystals from the system V–III are isomorphic with III; on heating those prepd. from 25–75% V at 100° for several hrs., the crystals become isomorphic with III. The system V–I forms a 1:1 mol. compd. similar in crystal form to III. I–II form mixed crystals (30–100% II) isomorphic with II. I–III

form a 1:1 compd., similar in crystal form to II. II–III form mixed crystals isomeric with II. C. J. West

Peroxidase-like action of π-oxocamphor. Morizo Isidate and Hukuko Sisido. *Proc. Imp. Acad.* (Tokyo) 15, 357–8(1939) (in German).—If a small quantity of *trans*-π-oxocamphor is added to a luminol test (*o*-aminophthalic hydrazide and H_2O_2) a blue chemiluminescence is observed at once, which may continue for several hrs., depending upon the amt. of H_2O_2 used. The reaction is strongly retarded by KCN, Na_2S, NH_2OH, N_2H_4, etc. This reaction is not produced by the *p*-, *o*-, 6- and 10-oxocamphors; HCHO, AcH, BzH, 2-furaldehyde, citral and other aldehydes are also inactive. C. J. West

Autoxidation of *trans*-π-oxocamphor and the influence of other oxocamphors. Morizo Isidate and Hidenobu Kawaffata. *Proc. Imp. Acad.* (Tokyo) 15, 353–6(1939) (in German).—Curves are given of the rate of absorption of O by *trans*-π-oxocamphor and the effect of various admixtures on this rate. *p*-Oxocamphor has little effect; 0.005 mol. of the *o*-isomer almost completely inhibits the absorption of O; the same effect is produced by 1.5 to 2 equivs. of the 6-isomer. $FeSO_4$ has little effect; KCN and $CuSO_4$ are anticatalysts. *o*-Oxocamphor may be considered as a true org. anticatalyst. C. J. West

Constituents of Didymocarpus pedicellata. III. Isolation of a sesquiterpene and two polyterpene products and examination of the fatty matter. Sharifuddin Warsi and Salimuzzaman Siddiqui. *J. Indian Chem. Soc.* 16, 423–6 (1939); cf. *C. A.* 33, 5824⁴.—In the isolation of pedicin, pedicellin and 2 other allied coloring matters from the ethereal ext. of the leaves of *D. pedicellata* (*C. A.* 32, 4171³), the steam distn. of the final filtrates from pedicellin gave a light greenish yellow oil (I). Fractional distn. of 69 g. of I at reduced pressure yielded 64 g. of a sesquiterpene, *didymocarpene* (II), $C_{15}H_{24}$, b_3 136–7°, b_{12} 147–8°, $[\alpha]_D^{35}$ −3.7° (in 1% abs. alc.), d_4^{24} 0.8957, n_D^{29} 1.4988; *nitroso hisnitrosite*, $C_{30}H_{47}N_5O_8$, sky-blue prismatic rods, m. 132–4°. Titration with Br indicated the presence of 2 double bonds and II is apparently a bicyclic sesquiterpene. The residue left after the steam distn. of II was subjected to direct heating in a vigorous current of steam and the thick reddish oily distillate was fractionally dist., yielding 16 g. of *didymocarpol* (III), $(C_{10}H_{20}O)_6$, m. 76°, in white silky needles, optically inactive, satd. to Br, inert and stable to alk. or oxidative degradation; and 8 g. of silky needles of *didymocarpenol* (IV), $C_{26}H_{42}O$, m. 137°, $[\alpha]_D^{29}$ −65.5° (in 1% abs. alc.), adsorbing 2 atoms of Br. Lignoceric, behenic, stearic (V) and palmitic acids in nearly equal proportions were obtained by sapon. of the fatty nonvolatile residue from the steam distn. V was also isolated from the acid fraction of the original ether ext. Calcd. on the wt. of dried leaves, yields of 1.6, 0.3 and 0.15% of II, III and IV were obtained. **IV. Isolation of two new coloring matters and their relationship to pedicin.** *Ibid.* 519–24.—Tentative structures have been suggested for pedicellin (I), pedicin (II), pedicinin (III) and isopedicin (IV). The ease with which the 5-membered ring in III is formed from the chalcone, II, suggests that IV should have a 5- and not a 6-membered ring. This has been investigated by a closer study of II and IV. The isolation of IV in quantity was undertaken. Coarsely powd. leaves (2 kg.) of *D. pedicellata* were successively extd. with petr. ether and ether. The crude coloring matter from the concd. ether ext. was washed with concd. Na_2CO_3 and the mother liquor was shaken out with Na_2CO_3 and with dil. NaOH. The combined Na_2CO_3 exts. were acidified and extd. with ether and then with $CHCl_3$, yielding III as the least sol. fraction and crude *pseudoisopedicin* (V) from the mother liquors. The residue insol. in Na_2CO_3 gave II and the dil. NaOH ext. also gave II on acidification. The ether mother liquor was washed with dil. acid and H_2O and on working up as previously described gave I and a 2nd new coloring matter, *pedicidin* (VI). The ether ext. yielded 5 g. III, 4 g. II, 6 g. I, 4.7 g. V and 2.5 g. VI. A similar sepn. of the petr. ether ext. gave 16 g. II, 14 g. I, 4.8 g. V, very little III and no VI, together with the entire essential oils and fatty material. Flow sheets for the method of sepn. are given. V, $C_{18}H_{18}O_6$, m. 126°, is satd. to Br and, like IV, is easily converted into II by treatment with dil. alkali at room temp. A mixt. of II (0.3 g.) in 5 cc. alc. and 2.5 cc. HCl (d. 1.16) was refluxed for 18 hrs., concd. and dild. with H_2O. The mixt. was extd. with ether, washed with Na_2CO_3 and concd., yielding V. V gives the same color reactions as IV with alkali, H_2SO_4 and $FeCl_3$. It is probable that IV, m. 105°, is racemized into V on long standing. VI, $C_{37}H_{36}O_{11}$, m. 190°, takes up Br, gives nearly the same color reactions as IV, and is converted into a *deep red cryst. compd.*, m. 163–6°, by the action of HNO_3. VI may be formed by the condensation of 2 mols. of simpler coloring matters since it has 7 OMe groups. C. R. Addinall

Ionene. Arno Müller. *J. prakt. Chem.* 154, 82(1939); cf. *C. A.* 33, 1713⁴.—Purified ionene (1,1,6-trimethyltetralin), prepd. from α-ionone (Bogert and Fourman, *C. A.* 28, 145²), is a mixt. of 2 isomers, only one of which gives the color reaction with p-$Me_2NC_6H_4CHO$ and approx. 10% H_3PO_4 in AcOH. The latter (α-ionene) has the accepted ionene structure, while β-ionene is given the structure expected from its formation from β-ionone.

George Ayers

Polymorphism of benzophenone. Karl Schaum. *Ann.* 542, 77–90(1939).—In a general discussion of the question of polymorphism, measurements are given of the dielec. consts. of liquid, metastable and stable forms of Ph_2NH, 2,4-$(O_2N)_2C_6H_3Me$, 2,4-$(O_2N)_2C_6H_3OH$, Ph_2CO at 20°, $AcNH_2$, o-$O_2NC_6H_4Cl$, 2,4-$(O_2N)_2C_6H_3Cl$ at 18°, menthol at 21° and β-$C_{10}H_7OH$ and of the sp. cond. of β-$C_{10}H_7OH$ at temps. from 25 to 130°. The configuration of the stable (rhombic) and the metastable (monoclinic) forms is discussed. C. J. West

α-ω-Di-*p*-hydroxyphenylalkanes. Edwin M. Richardson and E. Emmet Reid. *J. Am. Chem. Soc.* 62, 413–15(1940).—In the following work ethylenic double bonds were reduced catalytically with PtO_2 and ketones by the Clemmensen method or the Martius modification. Demethylation was accomplished by refluxing 0.1 mole with 130 g. glacial AcOH and 50 cc. const.-boiling HBr. (4-$MeOC_6H_4CH_2)_2$, m. 125.5–7°, 72%; (4-$HOC_6H_4CH_2)_2$ (I), m. 198–9°, 94%; (4-$MeOC_6H_4CH)_2$, m. 100–1°, 95%; *1,3-di-p-methoxyphenylpropane*, m. 45–6°, 81%; *1,3-di-p-hydroxyphenylpropane* (II), m. 107–8°; *1,4-di-p-methoxyphenylbutane*, from 4-$MeOC_6H_4(CH_2)_3COCl$ and PhOMe, followed by reduction, m. 78–9°, 53%; *1,4-di-p-hydroxyphenylbutane* (III), m. 158–9°, 62%. (4-$MeOC_6H_4CH{:}CH)_2CO$ (92% yield from Me_2CO and p-$MeOC_6H_4CHO$) gives (4-$MeOC_6H_4CH_2CH_2)_2CO$, m. 55–5.2°; Clemmensen reduction gives 63% of $(CH_2)_5(C_6H_4OMe\text{-}4)_2$, which yields 92% of $(CH_2)_5(C_6H_4OH\text{-}4)_2$ (IV), m. 104–5°. Adipoyl chloride (1 mole) and 2 moles of PhOMe with 2.25 moles $AlCl_3$ in 500 cc. CS_2 give 85% of *1,4-di-p-methoxybenzoylbutane*, m. 145–6°; reduction yields 62% of *1,6-di-p-methoxyphenylhexane*, m. 70–1°, which gives 90% of *1,6-di-p-hydroxyphenylhexane* (V), m. 144.5–5.5°. Sebacoyl chloride gives 90% of *1,8-di-p-methoxybenzoyloctane*, m. 119–19.5°, which is reduced to 58% of *1,10-di-p-methoxyphenyldecane*, m. 69–70°; demethylation yields 74% of *1,10-di-p-hydroxyphenyldecane* (VI), m. 138.5–9.5°. The following values are for the soly. (g./100 cc.) in H_2O and olive oil (temp. not given), partition coeff. and max. killing dilns. for *Staphylococcus aureus:* $CH_2(C_6H_4OH\text{-}4)_2$ 0.3950, –, –, 300; I 0.0116, 0.10, 8.62, 1000; II 0.0381, 6.88, 180, 2000; III 0.0024, 0.67, 280, 5000; IV 0.0044, 10.47, 2400, –; V insol., 0.62, –, –; VI insol. 0.09, –, –. The partition coeff. and the max. killing dilns. both increase rapidly with the length of the intervening C chain; the low soly. of these compds. made extensive testing impossible. C. J. West

Action of sodium nitrite on Michler's hydrol in hydrochloric acid. Alexander Cantlay Hutchison and Thomas Harold Reade. *J. Chem. Soc.* 1940, 93–6.—From $NaNO_2$ (4 mols.) and Michler's hydrol (I) (1 mol.) in excess of 4.8 *N* HCl at 0° there were isolated 4-$O_2NC_6H_4NMeNO$, p-$ONMeNC_6H_4CHO$, p-$O_2NC_6H_4NMe_2$, p-$ONC_6H_4NMe_2$ and 3,4-$O_2N(Me_2N)C_6H_3CHO$. In 1.2 *N* HCl the reaction was somewhat less vigorous; the yields of p-$O_2NC_6H_4NMe_2$ and p-$ONC_6H_4NMe_2$ were increased and those

of the nitrosoamines were diminished. To account for the production of these 5 substances, 2 modes of fission of the I are required as suggested by the following equations: $Me_2NC_6H_4CH(OH)C_6H_4NMe_2 \rightarrow Me_2NC_6H_4CHO + PhNMe_2$; I + $6HNO_2 \rightarrow Me_2NC_6H_4CHO + O_2NC_6H_4NMe_2 + 2NO + 2H_2O$. The products of these equations would then react further with the HNO_2 and give the final substances isolated. Although the expts. do not lend themselves to quant estn., it is evident from the yields obtained in both acid concns. fission according to the 1st equation accounts for about $^2/_3$ of the original I and is the main reaction but that fission according to the 2nd equation is governed by the *N* of the acid and accounts for about 0.25 of the I in 1.2 *N* acid and about $^1/_{40}$ in the 4.8 *N* HCl; thus $^2/_3$ of the original I is accounted for as fission products; non-fission products may not be entirely absent from the oils encountered. In the expts. in which nitrosoamines were isolated, HCHO was also present. C. J. West

Fluorene (and its derivatives). B. A. Porai-Koshits. *Org. Chem. Ind.* (U. S. S. R.) **6**, 448–54(1939).—A review of literature with 100 references. Chas. Blanc

Remarks on the structure of fluorene. Ernst Bergmann and T. Berlin. *J. Am. Chem. Soc.* **62**, 316–17(1940).—This work supplements that of Lothrop (*C. A.* **33**, 7769[5]). Heating 4.1 g. of 2-acetoxyfluorene (I) with 3.6 g. $AlCl_3$ in 30 cc. $PhNO_2$ for 3 hrs. at 80° gives 0.6 g. of *1-acetyl-2-hydroxyfluorene* (II), yellow, m. 159°; it does not form an oxime. 2-Acetoxyfluorenone gives *1-acetyl-2-hydroxyfluorenone* (III), red, m. 206°; heating with $N_2H_4.H_2O$ in EtOH for 3 hrs. gives the *pyridazine deriv.* of III, yellow, m. 197° (decompn.). Boiling 1-benzoylfluorenone with $N_2H_4.H_2O$ in EtOH for 2 hrs. gives the *compd.* $C_{20}H_{12}O_2$, yellow, m. 181°. Rearrangement of I at 115° does not give II but a *compd.* $C_{15}H_{12}O_3$, m. 249°. 2-Hydroxyfluorenone (4 g.), allyl bromide and KOH in EtOH, heated 10 hrs., give 2.2 g. of the *2-allyloxy deriv.* (IV), m. 84–5°. Heating 1 g. of IV at 200° for 3 hrs. gives 0.6 g. of a *mol. compd.* of 1-allyl-2-hydroxy- and 3-allyl-2-hydroxyfluorenone, orange-red, $b_{0.05}$ 186°, m. 125–6°; catalytic reduction in PrOH gives a mixt. of 2 isomers, yellow, m. 202°, and dark yellow, m. 155° (sepd. from 1:1 aq. EtOH), apparently the *1-* and *3-propyl-2-hydroxyfluorenones*. This indicates that in fluorenone the double bonds have no fixed position. C. J. West

Some condensation products of *m*-dialkylaminobenzaldehyde with compounds containing reactive methylene groups. Wesley Cocker and Denys G. Turner. *J. Chem. Soc.* **1940**, 57–9.—In this work dyeing expts. were made with ppts. obtained by pouring boiling EtOH solns. into a large excess of cold water; 0.25 g. of the dried ppt. was triturated with 2 cc. Turkey-red oil and introduced into 120 cc. H_2O contg. 0.25 g. Lux soap; the soln. was warmed to 40°, 4 g. of acetate silk introduced and the temp. maintained at 70–80° for 90 min. with periodical stirring; the fabric was washed with cold H_2O and dried or brightened by immersion into 0.5% lactic acid soln. for 30 min., rinsed and dried. 2,4-$(O_2N)_2C_6H_3Me$ (3 g.), 2.5 g. *m*-$Me_2NC_6H_4CHO$ (I) (cf. *C. A.* **33**, 7756[7]) and 0.25 cc. piperidine, heated on the water bath for 24 hrs., give 3.1 g. of *2,4-dinitro-3'-dimethylaminostilbene* (II), very dark red, m. 205°; it gives orange solns. and imparts a pale yellow shade to acetate silk, which is largely discharged by exposure to bright sunlight for 24 hrs. *3'-Diethyl analog* of II, very dark red, m. 153°; it gives pale pinkish yellow shades on the fabric but its light-fastness is poor (somewhat better than II). *3'-Dipropyl analog* of II, dark red, m. 132°; its shade on silk was brown-yellow but the discharge of the dye bath was not very good. I (5 g.), 3.8 g. of 2,4-$(O_2N)_2C_6H_3CH_2CO_2H$ and 0.25 cc. piperidine, heated 24 hrs. on the water bath, give 1.6 g. of *2,4-dinitro-3'-dibenzylaminostilbene*, orange-red, m. 163°; it gives pale champagne shades on silk. Similarly 2.5 g. I and 2.7 g. *p*-$O_2NC_6H_4CH_2CN$, heated for 3 hrs., give 3.7 g. of *3-dimethylamino-α-4'-nitrophenylcinnamonitrile* (III), dark red, m. 162.5°; the rich golden yellow shades on silk fade to primrose-yellow after 16 hrs. in bright sunlight. *3-Diethyl analog* of III, dark red, m. 136°; it gives orange-yellow shades on silk, rapidly fading in bright sunlight. *3-Dipropyl analog* of III, orange-red, m. 108° (max. yield, 65%); the bright yellow shades fade rapidly in sunlight. *3-Diallyl analog* of III, bright orange, m. 82° (90% yield); the bright yellow shades fade almost completely after 16 hrs. under the ultraviolet lamp. I (2.5 g.), 3 g. *p*-$O_2NC_6H_4CH_2CO_2H$ and piperidine, heated 16 hrs. on the water bath, give 1.7 g. of *3-dimethylamino-α-4'-nitrophenylcinnamic acid* (IV), orange-yellow, m. 215.5°; it has little affinity for acetate silk; from 3 *N* NaOH or Na_2CO_3 the Na salt seps. as bronze plates; heating 1 g. IV with 0.5 cc. piperidine for 0.5 hr. at 140–5° gives *4-nitro-3'-dimethylaminostilbene* (V), deep orange, m. 145–5.5°; it gives very bright lemon-yellow shades on acetate silk. *3-Diethyl analog* of IV, orange, m. 173°; of V, orange-red, m. 97°; the shade on silk resembles that of V. *3-Dipropyl analog* of IV, bright yellow, m. 180.5°; of V, orange-yellow, m. 79°; it gives a bright yellow shade on silk. I, 3 g. of 1-phenyl-3-methyl-5-pyrazolone and piperidine, heated on the water bath for 6 hrs., give 2.3 g. of *1-phenyl-4-(3'-dimethylamino)benzylidene-5-pyrazolone*, deep red, m. 117°; the very pale ivory shade on silk is stable for many hrs. under the ultraviolet lamp. I, 4 g. α-picoline-MeI and piperidine, heated 6 hrs. on the water bath, give 2.5 g. of *2-m-dimethylaminostyrylpyridine-MeI*, deep orange, m. 237°; the EtOH soln. is reddish yellow and it gives a vivid lemon-yellow shade on silk; *2-m-diethylamino analog*, orange-red, m. 208°; the EtOH soln. is orange and the shade in silk is rich orange-yellow; *2-m-dipropylamino analog*, deep red, m. 192°; it gives orange shades on silk. I and quinaldine-MeI give *2-m-dimethylaminostyrylquinoline-MeI*, purple or black, m. 261°; it dyes silk a pale mauve-pink shade. *2-m-Dimethylaminostyrylthiazole-MeI*, bright red, m. 218°; it gives golden-yellow shades on silk. *2-m-Dimethylaminostyrylbenzothiazole-MeI*, purple-brown, m. 205° (21% yield); it gives beige shades on silk; *2-m-diethylamino analog*, brown, m. 188°. C. J. West

Action of oxalyl chloride on phenolic ethers. P. C. Mitter and Hitendranath Mukherjee. *J. Indian Chem. Soc.* **16**, 393–5(1939).—Condensation of $(COCl)_2$ (I) with MeOPh (II) and *o*-$MeOC_6H_4Me$ (III) gives *o*-diketones but only the corresponding acids are obtained with *m*-$MeOC_6H_4Me$ (IV) and *p*-$MeOC_6H_4Me$ (V). With *o*-$MeOC_6H_4OMe$ (VI), 3,4-$(HO)_2C_6H_3CO_2H$ is produced. A mixt. of 10 g. II in 50 cc. CS_2 and 6.3 g. I was chilled and treated with 20 g. $AlCl_3$ in portions with stirring. After standing overnight, the CS_2 was decanted and the reddish solid was decompd. with iced HCl. The reaction mixt. was heated, filtered and the residue was digested with Na_2CO_3 and recrystd. from alc., yielding 90% of anisil, m. 132° (oxidized by H_2O_2 in AcOH at 70–80° for 4 hrs. to anisic acid) and a small amt. of salicylic acid. A similar condensation of I with III gave a *diketone* (VII), $C_{18}H_{18}O_4$, oxidized by H_2O_2 to 4-methoxy-*m*-toluic acid. Alkali fusion of 3 g. VII with 10 g. NaOH at 180° in a Ni basin and acidification of the melt gave 4,4'-dimethoxy-3,3'-dimethylbenzilic acid, $C_{18}H_{20}O_5$, m. 145–7°. Condensation of I with V gave only 5-methylsalicylic acid, m. 149°, and with IV, the corresponding 3-methylsalicylic acid, m. 167–8°. With VI only protocatechuic acid, m. 189°, was produced. C. R. Addinall

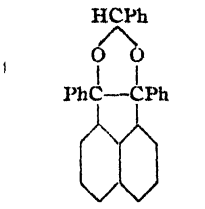
Ketocyclol tautomerism of 1,6-diketones. 1,4-Dibromo-1,4-dibenzoylbutane. Tsi-Yu Kao. *J. Am. Chem. Soc.* **62**, 356–8(1940).—Treatment with mol. Ag converts $(CH_2CHBrBz)_2$ into a mixt. of $(CH_2CH_2Bz)_2$, 13% of 1,2-dibenzoylcyclobutane and, as the principal product (37%), 1-phenyl-5-benzoyl-1-cyclopentene oxide (I). Refluxing 4.2 g. $(CH_2CHBrBz)_2$ and 17 g. Et_2NH in 30 cc. C_6H_6 for 30 min. gives 59% of 1-phenyl-5-bromo-5-benzoyl-1-cyclopentene oxide (II), m. 138–9°; poor yields were obtained with NaCN or AcONa. With $CHNa(CO_2Et)_2$ $(CH_2CHBrBz)_2$ gives 64% of II. Treatment of II with Zn dust and NaI in Me_2CO converts it into I. These transformations are interpreted on the assumption that the dibromide exists in tautomeric keto and cyclol forms. C. J. West

The 1,2,4-trimesityl 1,4-diketones and related com-

pounds, including the stereoisomeric mono- and dienols. Robert E. Lutz and Charles J. Kibler. *J. Am. Chem. Soc.* **62**, 360-72(1940).—The prepn. of the following series of compds. was undertaken to extend the study of the hindering effect of mesityl groups. $(RCOCH)_2$(R = $Me_3C_6H_2$) (5.7 g.), added in 0.5-g. portions to 4 equivs. of RMgBr in abs. Et_2O at 20°, gives a clear brown soln. of RCOCHRCH:C(OMgBr)R (I); decompn. with dil. HCl yields 5.3 g. of *1,2,4-trimesitylbutane-1,4-dione*, RCOCHRCH$_2$COR (II), m. 147-7.5° (all m. ps. cor.); Br in $CHCl_3$ did not give a cryst. product; reaction with MeMgI at room temp. indicates 1 active H atom; at 100°, 15 hrs. were required for 0.5 mol. more of CH_4 to form. Dehydration of II with Ac_2O and H_2SO_4 in the usual way failed; refluxing 0.5 g. II in 15 cc. concd. AcOH and 0.6 cc. H_2O for 30 hrs. with a continuous stream of dry HCl passing through at the rate of about 20 bubbles per min. gives 0.54 g. of *2,3,5-trimesitylfuran* (III), m. 106.5°; heating 0.2 g. II and 1 cc. HI at 160 70° for 1 hr gives 50% III; 0.2 g. II, 8 cc. AcOH, 6 drops HI and 0.1 g. each of red P and I, refluxed 1 hr., give 0.13 g. III. III and PBr_5 at 90° for 0.5 hr. give an amorphous *tetrabromide*, m. 120-50°. HNO_3 in AcOH at 15° gives the *4(?)-NO_2 deriv.* of III, m. 206.5-7°. The soln. of I from $(RCOCH)_2$ and 2 equivs. of RMgBr, decompd. by I in EtOH at 0-10°, gives 74-9% of *3-iodo-1,2,4-trimesitylbutane-1,4-dione A* (IV), m. 213° (decompn.); various methods of reduction yield II. Solns. of the Mg 4-monoenolate B from the action of MeMgBr, EtMgBr or PhMgBr upon II, poured into cooled EtOH-I, give the *B isomer* (V) of IV, m. 178°; V and EtMgBr at 20° give II, as does reduction with $NaHSO_3$ in boiling 60% EtOH; KOH in boiling EtOH gives VI. The *3-Br analog* of IV m. 192.5 3.5°; EtMgBr at 20° enolizes the Br compd. and decompn. with EtOH-I gives a good yield of IV; it is not affected by boiling with AcONa in EtOH but MeOH-KOH (30 min.) gives VI; reduction with $NaHSO_3$ in 60% EtOH (refluxing 4 hrs.) gives II. The *Br analog* of V m. 230 1° and is similarly prepd. except that EtOH-Br is used; EtMgBr reacts rapidly at 20° and decompn. with EtOH-I gives V; reduction with Zn and AcOH gives II; KOH in 95% EtOH gives a quant. yield of VI. Refluxing 4 g. V in 125 cc. EtOH with 3 g. KOH for 1 hr. gives 90% of *1,2,4-trimesityl-2-butene-1,4-dione* (VI), m. 142 4°; it does not react with Ac_2O-H_2SO_4 and is unchanged by sunlight in EtOH or $CHCl_3$ contg. I; reduction with Zn and AcOH gives III but $NaHSO_3$ in dil. EtOH did not reduce VI. The monoenolate, obtained by the 1,4-addn. of RMgBr to $(RCOCH)_2$ is designated 1,2,4-trimesitylbutane-1,4-dione-4-enolate A (VII); it is also obtained by the action of a Grignard reagent on IV or V or the Br compds.; reaction with I and Br gives IV or the Br deriv.; decompn. in an EtOH soln. of quinone or $K_3Fe(CN)_6$ produced only II but no VI; decompn. by dil. HCl gives only II; dropping the Et_2O soln. into boiling AcOH gives only II; RMgBr in $(iso\text{-}Pr)_2O$ with refluxing for 2 hrs. in a N atm. gives IX; in ether only IV is formed, showing that the higher temp. is necessary to produce IX; PhMgBr (refluxing 5 min. in Et_2O) gives X. VII results most conveniently from the reaction of IV and 3-4 equivs. of PhMgBr in Et_2O at 20° for 2-3 min. The 4-monoenolate B results from the action of Grignard reagents in Et_2O on II at room temp. VI (8 g.), 20 g. Zn and 125 cc. AcOH, refluxed 1 hr., give 60% of *1,2,4-trimesitylbutane-1,4-dione-1-monoenol. A* (VIII), m. 131-1.5°; it seps. from EtOH with H_2O of crystn.; heating with I, red P and AcOH gives III. Refluxing with KOH in 95% EtOH gives VI. 1,2,4-Trimesitylbutane-1,4-dionedienolate A (IX) results from VII as above or by refluxing VIII and PhMgBr in Et_2O for 30 min.; EtOH-I gives VI; boiling AcOH gives II; refluxing with AcOH gives VIII. The IX from VIII, treated with EtOH-AcOH and then H_2O gives the free *dienol*, m. 72-3°; on standing in the air for 1 week it gives VI in quant. yield; I in EtOH also gives VI; heating with AcOH contg. a little HCl gives II. The dienolate B (X) results by enolization of VII in ether or by the action of PhMgBr on IV in ether (refluxing 5 min.); it differs from IX by its soly. in ether; EtOH-I gives VI; boiling AcOH gives III. There is a long discussion of the various reactions and of the mechanism of furan-ring closure. C. J. West

Molecular compounds between naphthalene, its α- and β-derivatives and aromatic nitro compounds. IV. Binary molecular compounds of naphthalene and naphthols with mononitro derivatives of benzene. Tiro Sinomiya. *J. Chem. Soc. Japan* **60**, 170-82(1939).—Mol. combination of $PhNO_2$ and its substitution products with naphthalene and α- and β-naphthol has been investigated by making temp.-concn. diagrams. The results obtained are compared with those for the trinitro (*C. A.* **32**, 9075[9]) and dinitro (*C. A.* **32**, 9076[8]; **33**, 563[6]) compds. The nitro compds. examd. are *o*-, *m*- and *p*-$O_2NC_6H_4CO_2H$, *o*-, *m*- and *p*-$O_2NC_6H_4CHO$, *m*- and *p*-$O_2NC_6H_4Cl$, *o*-, *m*- and *p*-$O_2NC_6H_4OH$, *m*- and *p*-$O_2NC_6H_4Br$, *m*-$O_2NC_6H_4Me$ and *o*-, *m*- and *p*-$O_2NC_6H_4NH_2$. The results indicate that (1) α-naphthol has a greater tendency to form mol. compds. than β-naphthol. (2) The reactivity of nitro compds. decreases with the decrease in no. of nitro groups. Among mononitro compds. only *m*- and *p*-$O_2NC_6H_4CO_2H$, *m*- and *p*-$O_2NC_6H_4CHO$, and *p*-$O_2NC_6H_4Cl$ form mol. compds. The reactivity is in the order, $CO_2H > CHO > Cl$ with different groups and *p*- > *m*- > *o*- with the same group. Both orders correspond to those of the dinitro compds. The order of reactivity of naphthalene, α- and β-naphthol toward *m*- and *p*-$O_2NC_6H_4CO_2H$ is $C_{10}H_8 > \alpha\text{-} > \beta$-naphthol. In this case CO_2H combines with naphthalene nucleus. Formerly it has been considered that CO_2H, like NO_2, reacts with the double bond to form a mol. compd. and its reactivity increases when the NO_2 is present at the *m*- or *p*-position to CO_2H. When NO_2 is present at the *o*-position, however, CO_2H does not show reactivity, e. g., *o*-$O_2NC_6H_4CO_2H$ combines neither with $C_{10}H_8$ nor with α-naphthol. This ortho effect, however, varies as the difference in the natures of the 2 adjacent groups become greater, e. g., the 3 $O_2NC_6H_4CHO$ do not combine with $C_{10}H_8$ but combine with naphthol. Similarly *o*-$O_2NC_6H_4CO_2H$ has considerable affinity toward α- and β-naphthylamine. Isolation of mol. compds. from solns. of those mixts. has been unsuccessful, although the T-C diagrams indicate their formation. K. S.

Steric hindrance in ketone-naphthol condensation. The condensations of the naphthols with cyclohexanone. Joseph B. Niederl, Victor Niederl and Jesse Charney. *J. Am. Chem. Soc.* **62**, 322 3(1940).—Condensation of 0.5 mol. quantities of α-$C_{10}H_7OH$ (I) and cyclohexanone (II) by passing dry HCl through the system at 30° for 6 hrs. and allowing the soln. to stand 12 hrs. at room temp. gives 80% of *1-(4'-hydroxynaphthyl)cyclohexene*, m. 80°; it couples with *p*-$O_2NC_6H_4N_2Cl$; *acetate*, m. 94°; *dibromide*, m. 147° (20% yield). Condensation of I and II at 100° gives 50% of *1,1-di(4'-hydroxynaphthyl)cyclohexane*, m. 233°; it also couples with *p*-$O_2NC_6H_4N_2Cl$; *dibenzoate*, m. 223°. Condensation of β-$C_{10}H_7OH$ and II (as described for I but allowed to stand 2 weeks) gives 20% of *2,3-tetramethylene-4,5(or 5,6)-benzocoumaran*, m. 66-8°; it did not couple with *p*-$O_2NC_6H_4N_2Cl$ and did not yield an Ac deriv. C. J. West



Preparation of 1,2-naphthalenediamine-5-sulfonic acid. I. I. Vorontsov, L. M. Ivanova and O. F. Avdeeva. *Org. Chem. Ind.* (U. S. S. R.) **6**, 441-5(1939).—A yield of 74% of com. 1,2,5-$(H_2N)_2C_{10}H_5SO_3H$ is obtained from 1,5-$H_2NC_{10}H_6SO_3H$, a by-product in the production of 1,8-acid, by coupling it with diazotized $PhNH_2$ and cleaving the azo dye by reduction with Fe turnings in a neutral medium at 95-8°. Equally good results can be obtained by reducing the azo compd. with $SnCl_2$ and HCl and with Zn dust in alk. medium. Chas. Blanc

Synthesis of analogs of Fast Black Base LB. B. M. Bogoslovskiĭ and L. M. Tsil'man. *Org. Chem. Ind.* (U. S. S. R.) **6**, 445-8(1939).—*Echtschwarzbase LB* (I), obtained from diazotized *o*-anisidine and 1-$C_{10}H_7NH_2$ (II) (Ger. pats. 383,903 and 403,931), gives excellent black ice dyeings on fiber impregnated with naphthols of the AS group. I analogs were prepd. by substituting 2-amino-4-nitroanisole (III) and 2-nitro-4-aminoanisole (IV) for the expensive *o*-anisidine. The required 2,4-dinitroanisole

(V), m. 86°, was prepd. in 93.3% yield by treating dropwise at room temp. 76.5 g. of 2,4-$(O_2N)_2C_6H_3Cl$ in 150 ml. MeOH with 22 g. KOH, stirring for 2 hrs., filtering and drying at 30–40°. III, m. 113°, resulted in 93% yield by reducing V in H_2O with $NaHSO_3$ and in 47.6% yield by satg. 10 g. V in 40 ml. alc. with NH_3 in the cold and then with H_2S on a water bath, adding 200 ml. H_2O, filtering and drying. IV, m. 46–7°, was prepd. in 72% yield by sapong. 6 g. 2-nitro-4-acetylaminoanisole (VI) in 100 ml. of 20% H_2SO_4 at 95–6° for 2 hrs. and neutralizing the cold soln. with 25% NH_4OH. VI, m. 144 5°, prepd. by nitrating acetyl-*p*-anisidine, m. 128° (Ger. pat. 101,778). *3-Nitro-4-methoxybenzeneazo-1-naphthylamine* (VII) resulted in 100% yield by dissolving 4.2 g. IV in 50 ml. H_2O and 13 ml. of concd. HCl at 80°, treating the soln. at 0° with 10% $NaNO_2$ and then dropwise with 3.75 g. II in 100% AcOH and continuing the stirring (22 hrs. in all). VII is filtered and dried at room temp. *5-Nitro-2-methoxybenzeneazo-1-naphthylamine* (VIII) was similarly prepd. in 95% yield from III and II. VII and VIII can also be obtained in 90% yield by coupling III and IV, resp., with II suspended at 70° in water with the addn. of green soap. The reaction requires 35 instead of the 22 hrs. of stirring. They form black powders with a bronze luster, insol. in water and Et_2O, poorly sol. in alc. and sol. in concd. H_2SO_4, AcOH and HCO_2H and hot MeOH. Coupling of diazotized III and IV with Cleve's acid in a slightly alk. medium gave 90% of the corresponding 6-sulfonic acids of VII and VIII. The dye bath is prepd. by dissolving 1 g. VII or VIII in 4 ml. of 85% HCO_2H, adding 30 ml. H_2O and 1 ml. of concd. HCl and treating the soln. with 0.26 g. $NaNO_2$ in 2 ml. H_2O. After the addn. of 1 g. NaOAc in 2 ml. H_2O, the soln. is applied to cloth impregnated with naphthols of the AS group, giving deep black dyeings fast to washing and insolation (2 months). The sulfonated VII and VIII gave brownish black dyeings with inferior stability. Chas. Blanc

Vitamin K activity of naphthoquinones. Erhard Fernholz, S. Ansbacher and H. B. MacPhillamy. *J. Am. Chem. Soc.* **62**, 430 2(1940); cf. *C. A.* **34**, 1650⁴.—Palmitoyl chloride and tetralin in CS_2 with $AlCl_3$ give 56% of *pentadecyl 5,6,7,8-tetrahydro-2-naphthyl ketone*, m. 44–5°; Clemmensen reduction gives 63% of *2-hexadecyl-5,6,7,8-tetrahydronaphthalene*, b_1 210–15°; heating with S at 200 10° for 5 hrs. gives 20% of 2-hexadecylnaphthalene, b_1 200°, m. 45–6°; CrO_3 in AcOH, heated at 60° for 1.5 hrs., gives 37% of *2-hexadecyl-1,4-naphthoquinone* (I), m. 80–1°. Similarly prepd., the *2-octadecyl deriv.* (II) m. 84–5° (23%). 2-Methyl-5,6,7,8-tetralin and stearoyl chloride give 36% of *heptadecyl 5,6,7,8-tetrahydro-3-methyl-2-naphthyl ketone*, m. 64–5°; *2-methyl-3-octadecyl-5,6,7,8-tetrahydronaphthalene*, m. 60 1°; S dehydrogenation yields 35% of *2-methyl-3-octadecylnaphthalene*, m. 47 8°, which gives 37% of *2-methyl-3-octadecyl-1,4-naphthoquanone* (III), m. 95–7°. The following assay results are reported: inactive, 1,2-naphthoquinone; weakly active in a dose of 1 mg., 2,6-di-Me, 2-allyl and 2,3-diallyl derivs. of 1,4-naphthoquinone, and I and II; 1 unit per mg., 1,4-naphthoquinone and its 2-Et and 2-Pr derivs., also III; 20 units per mg., 2,3-dimethyl-1,4-naphthoquinone; 70 units per mg., vitamin K_1. Because of these results it appears that the prepn. of other naphthoquinones would not lead to the discovery of a substance surpassing in activity 2-methyl-1,4-naphthoquinone. C. J. West

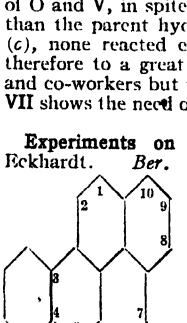
Autoxidation of benzaldehyde in the presence of 9,10-diphenylacenaphthylene. Georg Wittig and Konrad Henkel. *Ann.* **542**, 130 44(1939); cf. *C. A.* **33**, 9781.—Curves are given showing that 9,10-diphenylacenaphthylene (I) inhibits the autoxidation of BzH. Shaking 1 g. I with 30 cc. BzH until the original orange color becomes a light yellow gives 65% of the *cyclic acetal* (II) of *cis*-9,10-diphenylacenaphthylene glycol (III), m. 249–9.5°; II also results in 0.47 g. yield from 0.5 g. III or the trans isomer and BzH with gaseous HCl. II is sol. in concd. H_2SO_4 with an olive-green color. Heating II with HCl-AcOH gives diphenylacenaphthenone and BzH. The di-K or the di-Li complex of I and $PhCHCl_2$ in Et_2O, heated at 100° for 24 hrs., give 1,8-$C_{10}H_4Bz_2$ (IV). I does not react with BzO_2H in $CHCl_3$; the product from I, BzH and BzO_2H in $CHCl_3$ (7 hrs. at 25° in N) is IV; II was not observed. I is unchanged by stilbene or chlorostilbene ozonides.

(II)

These reactions were studied in an effort to ascertain the mechanism of the formation of II. The presence of I has little effect on the oxidation of BzH under the influence of light. C. J. West

Haloacenaphthenes. M. M. Dashevskiĭ and A. P. Karishin. *Org. Chem. Ind.* (U. S. S. R.) **6**, 507–11 (1939); cf. *C. A.* **32**, 2111⁹, 4974⁶.—Studies of *4,5-dichloroacenaphthene* (I) and its derivs. are continued by prepg. I from acenaphthene (II) and its 4-Cl deriv. (III) and $SOCl_2$ by the modified method of Morgan and Harrison (*C. A.* **25**, 3988). The sulfonic acids of I and 4,5-dibromoacenaphthene (IV) and their oxidation products are described for the 1st time. The chlorination was carried out in the presence and absence of the catalyst and solvents by allowing the reaction mixt. to stand at room temp. for 1–2 days, with occasional shaking, until the liberation of HCl had stopped. The filtered ppt., when washed with petr. ether and recrystd. from alc., gave I, m. 169–70°. The best results were obtained without a solvent in the presence of 0.3 g. I, *viz.*, 60% I from 63 g. III and 50 ml. $SOCl_2$ and 50% I from 50 g. II and 70 ml. $SOCl_2$. The reaction in solvents in the presence of I proceeds better in C_6H_6 than in CCl_4 and in the absence of I better in CCl_4. Other solvents ($CHCl_3$, AcOH and petr. ether) gave impure I in lower yields. Heating 1 hr. on a water bath I with 2 parts by wt. of concd. H_2SO_4 gave 100% *4,5-dichloroacenaphthene-2-sulfonic acid* (V), m. 192° (decompn.). V, treated with PCl_5, gave the *chloride* (VI), m. 175°. *Amide*, m. 270 2° (decompn.) (prepd. from VI and 10% alc. NH_3OH), when treated with Na-Hg in abs. alc., gave acenaphthene-2-sulfonamide, m. 199° (cf. Dziewonsky, *et al.*, *C. A.* **22**, 1154; **27**, 4534). Oxidation of V with $K_2Cr_2O_7$ in glacial AcOH gave *4,5-dichloro-2-sulfonaphthalic acid*, m. 229–30°; it forms the anhydride at 160°. Its *sulfonyl chloride* m. 219–20°, and *amide* does not m. 380–2° (decompn.). I with 4 parts by wt. of concd. H_2SO_4 gave a mixt. of V and *2,7-disulfonic acid* (VII), which were sepd. as Ba salts. VII, m. 265 6°, formed the *chloride*, m. 198–200°, and *diamide*, does not m. 400°. *4,5-Dichloro-2,7-disulfonaphthalic acid*, m. 176–7° (decompn.). IV, obtained by the method described in an earlier paper, gave compds. analogous to I. *2-Sulfonic acid*, colorless needles from AcOH, m. 240° (decompn.); *chloride*, m. 190–1°; *amide*, m. 260–2°. *4,5-Dibromo-2-sulfonaphthalic acid* m. 235–6° and forms the anhydride at 154°. *4,5-Dibromoacenaphthene-2,7-disulfonic acid*, colorless, m. 252° (decompn.); *chloride*, m. 197–8° (decompn.); *amide*, m. 274–5°. *4,5-Dibromo-2,7-disulfonaphthalic acid*, m. 159–60° (decompn.). Chas. Blanc

Polycyclic aromatic hydrocarbons. XXI. G. M. Badger, J. W. Cook and F. Goulden. *J. Chem. Soc.* **1940**, 16–18; cf. *C. A.* **33**, 33687.—6-Methyl-1,2-benzanthraquinone and MeMgI in C_6H_6-Et_2O, decompd. with NH_4Cl and the crude product triturated with C_6H_{12}-cyclohexane, give *9,10-dihydroxy-6,9,10-trimethyl-9,10-dihydro-1,2-benzanthracene* (I), m. 151–2°; if the crude product is treated with MeOH-HCl there results from 7.1 g. quinone 2.35 g. of the *9,10-di-Me ether* (II) of I, m. 232–3.5°. Shaking 2 g. II in Et_2O with 0.28 g. Na for 24 hrs. gives 1.5 g. of *6,9,10-trimethyl-1,2-benzanthracene*, yellow, m. 157–8°, purified through the *picrate*, lustrous purplish brown, m. 145–6°. The Grignard reagent (IIA) from 3-bromo-*o*-xylene and 1,2-$C_{10}H_6(CO)_2O$ in Et_2O-C_6H_6, boiled 2 hrs.,

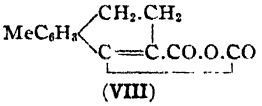


give *2-(2',3'-dimethylbenzoyl)-1-naphthoic acid* (III). Heating partially purified III with Ac_2O in C_5H_5N gives the *acetoxy lactone*, m. 189–91°, from which pure III, m. 168–9°, was obtained by hydrolysis with alc. KOH. III (5 g.) and 5 cc. BzCl with a few drops of concd. H_2SO_4, heated 1 hr. at 130°, give 95% of 5,6-dimethyl-1,2-benzanthraquinone which with MeMgI yields *9,10-dihydroxy-5,6,9,10-tetramethyl-9,10-dihydro-1,2-benzanthracene*, m. 217–19°; MeOH-HCl gives the *9,10-di-Me ether* (IV), m. 229–30°. Shaking IV with Na in ether gives *5,6,9,10-tetramethyl-1,2-benzanthracene*, pale yellow, m. 132–3°; *picrate*, purplish brown, m. 120–1°, the dissocn. of which is effected by passing its C_6H_6 soln. through Al_2O_3. IIA and 21 g. $C_6H_4(CO)_2O$ give 25 g. *2-(2',3'-dimethylbenzoyl)-benzoic acid*, m. 126–7°, which forms 80% of 1,2-dimethylanthraquinone (V), pale yellow, m. 154.5–5.5°; reduction gives 86% of *1,2-dimethylanthracene*, $b_{0.4}$ 180°, m. 85.5–6°; V and MeMgI give *9,10-dihydroxy-1,2,9,10-tetramethyl-9,10-dihydroanthracene*, m. 162 3°; *di-Me ether*, m. 140–1.5°; this ether is recovered unchanged after shaking with Na in Et_2O for 6 days. C. J. West

o-Halide synthesis of 10-methyl-1',9-methylene-1,2-benzanthracene. Louis F. Fieser and James Cason. *J. Am. Chem. Soc.* **62**, 432–6(1940).—Since attempts to introduce Me or HO groups into 1',9-methylene-1,2-benzanthracene by direct substitution offered little promise of success, a 2nd synthesis was investigated which affords a route not only to the parent hydrocarbon but to various 10-substituted derivs. The method embodies the general scheme of synthesis of anthracene derivs. of F. and Seligman (*C. A.* **33**, 1719[3]). This involves the prepn., through a Grignard reaction and reduction of a suitable *o*-halide of a diphenylmethane, conversion through the nitrile to the acid and ring closure. The halogen may be introduced in various sequences into either aromatic ring, giving considerable flexibility to the method. Com. 95% acenaphthene (I) (154 g.) in 1 l. AcOH at 60–70°, treated with 820 g. red lead (85–90%) (added in 50-g. portions over 40 min. with stirring), the reaction mixt. poured into 2 l. H_2O and the pptd. oil extd. with Et_2O, gives 170–5 g. of crude 7-acenaphthenyl acetate, b_6 166–8°; this yield is about that obtained with $Pb(OAc)_4$; hydrolysis with 40 g. NaOH in 400 cc. H_2O and 275 cc. MeOH (refluxing 2 hrs.) gives 70.5–4% of 7-acenaphthenol (II) (based on I), m. 144.5–5.5° (all m. ps. cor.). Oxidation of 100 g. II in 300 cc. AcOH with 43 g. CrO_3 in AcOH-H_2O, added during 50 min. at 28–32°, gives 65% of 7-acenaphthenone (III), m. 121–1.5°. III (45 g.) in 125 cc. C_6H_6 and 70 cc. Et_2O, added during 15 min. to *o*-ClC_6H_4MgBr (from 67.6 g. *o*-BrC_6H_4Cl), refluxed 15 min. and the reaction product decompd. with 55 cc. satd. NH_4Cl gives *7-(o-chlorophenyl)-acenaphthen-7-ol* (IV); crystn. from C_6H_6 gives only 15–20% of pure IV, m. 216–18°; the best over-all yield of *7-(o-chlorophenyl)acenaphthylene* (V), yellow-orange, m. 104–4.4°, results by the dehydration of the crude IV by refluxing with 225 cc. AcOH for 1 hr. and passing through a column of activated Al_2O_3 and Supercel (1:1); the yield of V suitable for hydrogenation is 33–6%. Catalytic reduction of 32 g. V in 155 cc. AcOH and 15 cc. Et_2O at room temp. (0.8 g. Adams catalyst) gives 95% of *7-(o-chlorophenyl)acenaphthene* (VI), b_2 190–2°, m. 81–2°. VI (35.6 g.), 11.5 g. CuCN, 3 cc. MeCN and 31 cc. C_5H_5N, heated in an autoclave under N (initial pressure 800 lb.) at 243–5° for 25 hrs. give 87% of *o-(7-acenaphthyl)benzonitrile* (VII), b_3 208–12°, m. 79.7–80.5°; longer heating decreases the yield of VII: 35 hrs., 74.5%; 48 hrs., 66.5%; 60 hrs., 20%. Refluxing 25.9 g. VII and 164 g. KOH in 1050 cc. EtOH and 590 cc. H_2O in a Cu flask for 25 hrs. gives 69% of *o-(7-acenaphthyl)benzoic acid* (VIII), m. 195–5.5°; if the hydrolysis is conducted at 120° (17 hrs.) the yield is only 5%; after 65 hrs. at 100° it is 40%; hydrolysis for 100 hrs. gives 32.5% of the *benzamide* (IX), m. 182–2.8°, and 40.5% of VIII. IX with $AmNO_2$ in AcOH gives only a nonacidic, amorphous, red material. Refluxing 0.5 g. VIII, 3 cc. AcOH, 2.5 cc. Ac_2O and a trace of $ZnCl_2$ for 1 hr. gives 83% of *10-acetoxy-1',9-methylene-1,2-benzanthracene* (X), straw-colored, m. 175–9°; boiling with AcOH causes decompn. but it may be recrystd. from boiling EtOH. Reduction of X with Zn and alkali gives 51.5% of 1',9-methylene-1,2-benzanthracene (XI) (overall yield in 10 steps from I, 3.8%). For the prepn. of XIII it is desirable to cyclize VIII under conditions most favorable for retaining the product in the anthrone form and avoiding enolization; the HF method was therefore used. VIII (5 g.) and 100 g. HF were allowed to stand for 15 min. and the crude dried product was added in 0.5-g. lots to 5 equivs. of MeMgCl in Et_2O; decompn. with dil. acid gives 43–54% of *1',9-methylene-1,2-benz-10-anthranol* (XII), pale yellow, m. 160–4° (decompn.); it turns red rapidly in boiling C_6H_6 or cold dioxane; XII is highly fluorescent in dil. EtOH soln. and $FeCl_3$ gives an orange-red color; extensive decompn. occurs on attempted acetylation. Reduction with Zn and alkali gives 35% of XI. Heating XII on a hot plate for a short time gives 0.8–1.2% of the *10-Me deriv.* (XIII) of XI, pale orange, m. 181–1.4°; the *trinitrobenzene deriv.*, bright orange, m. 182.5–3.2°, is not suitable for purifying XIII; the dark red picrate is too unstable to be useful as a deriv. LiMe in Et_2O gives the same yield of XIII as the Grignard reagent. The low yields seem to be due to extensive and rapid isomerization to the anthranol. XIII is of special interest because of its structural relationship to the potently carcinogenic 9,10-dimethyl-1,2-benzanthracene. C. J. West

Action of perbenzoic acid on aromatic hydrocarbons. Hans-Joachim Eckhardt. *Ber.* **73B**, 13–15(1940).—Fieser and co-workers (*C. A.* **33**, 574[9]) have shown that the carcinogenic hydrocarbons are to a certain extent characterized by special chem. reactivity. A large part, e.g., are oxidized by $Pb(OAc)_4$. Methylcholanthrene (I) and 3,4-benzopyrene (II) are attacked with special ease by this reagent and are followed, in order of decreasing reactivity, by the methyl-1,2-benzanthracenes, while 1,2,5,6-dibenzanthracene reacts only very weakly. A noteworthy fact is that the carcinogenic activity of these hydrocarbons decreases in the same order. It is therefore of interest to test other oxidizing agents for their reactivity toward aromatic hydrocarbons and E. has carried out expts. in which various compds. (0.625×10^{-3} mol. in $CHCl_3$) were treated with an excess of BzO_2H (100 cc. of 0.1 *N* soln., or 8 atoms active O per mol.), made up to 250 cc. with $CHCl_3$ and allowed to stand at 4°, and the amts. of BzO_2H used up were detd. at definite intervals of time. The substances studied were: (*a*) Carcinogenic hydrocarbons: I, II, 1,2-benzanthracene, 4- and 6-methyl-1,2-benzanthracene and III. (*b*) Derivs. of (*a*): 5-nitrobenzopyrene (IV), benzopyrene-5-aldehyde (V). (*c*) Noncarcinogenic hydrocarbons: fluorene, naphthalene, phenanthrene, anthracene (VI), chrysene and pyrene (VII). The carcinogenic hydrocarbons all reacted more or less (I and II most), while the physiologically inactive IV consumed only a trace of O and V, in spite of its CHO group, was attacked less than the parent hydrocarbon. Of the compds. of group (*c*), none reacted except VI and VII. The results are therefore to a great extent in harmony with those of F. and co-workers but the discrepancy in the case of VI and VII shows the need of caution in interpreting them.

C. A. R.



Experiments on 3,4-benzopyrene. Hans-Joachim Eckhardt. *Ber.* **73B**, 15–18(1940).—(The notation

is used in this paper.) Windaus and Raichle (*C. A.* **33**, 2133[9]) have shown that the Ac group in the acetyl-3,4-benzopyrene described by W. and Rennhak (*C. A.* **32**, 546[7]) is very probably on the 10-C atom, whereas in the nitrobenzopyrene (I) this position of the substituent is excluded. The work of Vollmann and colleagues (*C. A.* **32**, 145[9]) on pyrene and benzopyrene, who showed that the 3-, 5-, 8- and 10-C atoms are by far the most reactive, therefore made it probable that in I the

nitro group is at position 5 or 8. This working hypothesis was confirmed by oxidation expts. with CrO_3. On energetic oxidation (300 mg. I in 110 cc. boiling AcOH treated with 1.5 g. CrO_3 in 10 cc. AcOH-H_2O and refluxed 15 min.) I yielded benzanthrone-*peri*-dicarboxylic anhydride, m. 364–5° (decompn.), and hence the NO_2 group can have been only at position 5, 8, 9 or 10. Position 10 is excluded, as stated above, and so is 9, for Vollmann and co-workers have shown that in pyrene the 9-C atom is extraordinarily unreactive. Under milder conditions (1300 mg. I in 1300 cc. AcOH and 1.9 g. CrO_3 in 10 cc. AcOH-H_2O heated 15 min. at 90°) there was obtained a benzopyrenequinone mixt. contg. only traces of N and yielding on reductive acetylation benzopyrene-5,10- and 5,8-hydroquinone diacetates, m. 241° and 202–3°, resp. This eliminates position 8 for the nitro group in I, for an 8-nitrobenzopyrene on oxidation should give only pure benzopyrene-5,8-quinone or a mixt. of this with 5-nitrobenzopyrene-5,10-quinone. That I is the 5-nitro compd. has in the meantime been confirmed by Fieser and Hershberg (*C. A.* **33**, 6299[9]). C. A. R.

A novel natural quinone dye of a phenanthrofuran class. F. Wessely and Shiu Wang. *Ber.* **73B**, 19–24(1940).—Nakao and Fukushima (*C. A.* **29**, 788[5]) isolated from the Chinese drug *tanshen* (root of *Salvia miltiorrhizae*) 3 cryst. dyes, 1 of which, Tanshinone I Blue (I) is the subject of this paper. The empirical formula $C_{18}H_{12}O_3$ and the presence of 2 *o*-quinone O atoms have been confirmed. In oxidation expts. with either CrO_3 or H_2O_2 there was obtained, along with small amts. of other products not yet extensively investigated, a well-crystd. yellow *acid anhydride* $C_{13}H_6O_3$ (II), m. 196°, apparently identical with the degradation product described by N. and F. The corresponding *acid*, $C_{18}H_{10}O_4$ (III), m. 192° (decompn.), readily regenerates II. The compn. of II and the fact that 1 mol. AcOH is formed in its CrO_3 oxidation suggested that II is the anhydride of a methylnaphthalenedicarboxylic acid. Decarboxylation of III by heating the Na salt over a free flame yielded 1-$C_{10}H_7Me$, of which there are 6 possible dicarboxyl derivs. The 4,5-positions for the CO_2H groups (Me = 1) seemed improbable, for II, unlike naphthalic anhydride, is very easily esterified by alc. That II is the 5,6-compd. was established by its synthesis by the following reactions (R = *o*-MeC_6H_4): RCH_2CH_2Cl (IV) (+ $CH_2(CO_2Et)_2$) → $RCH_2CH_2CH(CO_2H)_2$ (V) (− CO_2) → $RCH_2CH_2CH_2CO_2Et$ (VI) (+ $(CO_2Et)_2$) → $RCH_2CH_2CH(CO_2Et)COCO_2Et$ (VII) (+ concd. H_2SO_4) → VIII (− H) → II. As 2 of the O atoms in I are present in the

(VIII)

form of an *o*-quinone, the presence of a 3rd condensed ring may be assumed in I, which could then be represented by the formula $C_{15}H_8O_2(:C_2H_4O)$ where $C_{18}H_8O_2$ is an 8-methyl-1,2-, 2,3- or 3,4-phenanthrenequinone (*C. A.* notation) residue. All efforts to characterize the O atom in the residue C_2H_4O failed and it can be present only in ether union. Since I on CrO_3 oxidation gives 2 mols. AcOH and 1 Me group attached to C is in the $C_{18}H_8O_2$ residue, the 2nd must be in the residue C_2H_4O. On catalytic hydrogenation I rapidly absorbs 1 mol. H and is decolorized, the quinone color being restored on shaking with air. Further absorption of H (between 3 and 4 mols. in all) is quite slow; there can therefore be no aliphatic double or even triple bond in the residue C_2H_4O. All the known facts are best explained by formulating this residue as —CMe:CH.O— or —CH:CMe.O— (forming part of a ring); its attachment to the rest of the mol. is possible only if the residue $C_{18}H_8O_2$ is a 3,4- or 1,2-phenanthrenequinone. I would then be 1 of 8 possible *methylphenanthrofuran-o-quinones*. The method of prepg. I, which differed materially from that of N. and F., will be described elsewhere. After repeated crystn. of the crude product from AcOH and xylene, I formed prisms with brown luster, m. 232–4°. Reductive acetylation (Zn dust, Ac_2O and NaOAc at 140–50°) gave a white cryst. *diacetate*, $C_{22}H_{16}O_6$, m. 209°, and reductive methylation (Zn dust and NaOH in hot alc., followed by treatment with Me_2SO_4) yielded a *di-Me ether*, $C_{20}H_{12}O_3$, faintly yellow, m. 93–4.5°. *Quinoxaline*, $C_{24}H_{16}ON_2$, obtained quantitatively from I and 2 mols. *o*-$C_6H_4(NH_2)_2$ in AcOH-EtOH on the water bath, brown crystals from ether, m. 221–2° and, after resolidification, m. 196°, but if the melt is seeded with the 222°-form it again m. 222°. *γ-o-Tolyl-α-carboxybutyric acid* (V), m. 139°, is obtained in 60–70% yield from 16.3 g. IV, 24.5 g. $CH_2(CO_2Et)_2$ and 3.7 g. Na boiled 18 hrs. in 55 cc. alc., followed by sapon. with KOH of the *di-Et ester*, b_9 185–7°. *Et γ-o-tolylbutyrate* (VI), b_9 140–50°; the free *acid*, m. 70.5°, was obtained quantitatively by heating V at 160°. *Di-Et α-oxalyl-γ-o-tolylbutyrate* (VII), from dry EtOK, $(CO_2Et)_2$ and III allowed to stand overnight, then decompd. with acid and taken up in ether, decomps. on distn. even *in vacuo* and was used without further purification. *1-Methyl-7,8-dihydronaphthalene-5,6-dicarboxylic anhydride* (VIII), from VII allowed to stand 1.5 hrs. at room temp. in 8 parts concd. H_2SO_4, faintly yellow, m. 161°, gave with S at 150–70° 80% of a yellow compd., m. 196.5°, which did not depress the m. p. of II and yielded the same *ethylimide*, faintly yellow, m. 181.5°, as did II. C. A. R.

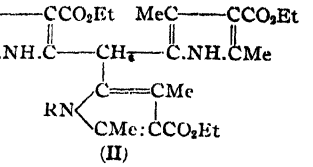
Sugar-amino-acid compounds. Tosinori Iseki and Tukouru Sugiura. *J. Biochem.* (Japan) **30**, 119–23 (1939).—In connection with the proposed synthesis of derivs. of hydroxymethylfurfural (I) which would be both carbohydrate and amino acid derivs. (*C. A.* **27**, 2953), I has been condensed with a no. of N-contg. compds. to obtain information on its reaction possibilities with amino compds. *Bis(pyromucamidemethyl) ether* [*bis(5-carbamylfurfuryl) ether*], [O.C(CONH$_2$):CH.CH:C-CH_2]$_2$O (98% from the corresponding bis(5-carbonyl chloride) (II) and 5 cc. concd. aq. NH_3 allowed to stand 14 days in the ice chest), m. 204°, sol. in hot water, alc. and AcOH. *Bis(5-phenylcarbamyl) analog* (100% from II and aniline in benzene), m. 169°, reacts acid to litmus, is sol. in org. solvents. *Bis(5-o-hydroxyphenylcarbamyl) compd.*, from *o*-$HOC_6H_4NH_2$, m. 329°, insol. in water, very little sol. in org. solvents. *Bis(Et pyromucurate-methyl) ether* [*bis(carbethoxymethylcarbamylfurfuryl) ether*]. [O.C(CO-NHCH$_2$CO$_2$Et):CH.CH:CCH$_2$]$_2$O, m. 107°, is obtained in 1.22 g. yield by adding 1.4 g. freshly distd. $H_2NCH_2CO_2Et$ (III) dropwise to 1 g. II in ice-cold acetone, filtering off the III.HCl which at once seps., concg. the filtrate without heat to 8 cc., adding 20 cc. dry ether and rubbing with a glass rod; it is hardly sol. in cold water but easily sol. in hot water and in org. solvents. Free *acid* (0.22 g. from 0.31 g. of the ester in 50 cc. water refluxed 70 min. with 14 cc. of 0.1 *N* NaOH), m. 223°. *Bis[5-(cinchoninic acid) furan-2-methyl] ether* [*bis(5-(4-carboxy-2-quinolyl)-furfuryl) ether*], from 1 mol. bis(5-formylfurfuryl) ether and 2 mols. $AcCO_2H$ in abs. alc. slowly treated with 2 mols. alc. aniline and refluxed 3 hrs., m. 251°, easily sol. in dil. alkalies, Na_2CO_3 and pyridine, very little sol. in org. solvents. C. A. R.

Dibenzofuran. XIII. Orientation and substituted amines. Henry Gilman, Paul T. Parker, James C. Bailie and Geo. E. Brown. *J. Am. Chem. Soc.* **61**, 2836–45(1939); cf. *C. A.* **33**, 6302[7].—Incidental to the detn. of structure of substituted amines, it is now shown that the generalizations on orientation postulated previously are adequate for the predominant products which result from polysubstitution of the dibenzofuran nucleus. Bromination of 4-methoxydibenzofuran (I) gives the 1-Br deriv. (IA), the Grignard reagent from which reacts with CO_2 to give 62% of *4-methoxy-1-dibenzofurancarboxylic acid* (II), m. 279–80° (decompn.), and with $(C_2H_4)_2O$ to give 59% of *1-β-hydroxyethyl-4-methoxydibenzofuran* (III), b_2 195–206°, m. 96–6.5°; passing dry HBr through III at 100° for 2.5 hrs. gives the *β-bromoethyl deriv.*, m. 91–1.5°; Et_2NH in EtOH at 100° for 6 hrs. gives 68% of the *1-β-diethylaminoethyl deriv.*, whose

HCl salt m. 187° (decompn.). I and AcCl with $AlCl_3$ in CS_2 give 66% of the *1-Ac deriv.* (IV), m. 134–4.5°; oxidation gives II; *oxime* of IV, m. 176–7.5°; Beckmann rearrangement with PCl_5 in C_6H_6 gives 95% of *1-acetamino-4-methoxydibenzofuran*, m. 222–3°; HNO_3 in AcOH gives 74% of the *Ac deriv.* (IVA), m. 244°, of *1-amino-2-nitro-4-methoxydibenzofuran* (V), m. 206–7°; through addn. of V in C_5H_5N to HNO_2 ($NaNO_2$ and H_2SO_4) at 5–10° there results 35% of *2-nitro-4-methoxydibenzofuran*, light yellow, m. 185–6°; *2-NH_2 deriv.*, m. 127–7.5°. 3-Aminodibenzofuran (VI) and nitrourea in EtOH give 66.5% of *3-dibenzofurylurea*, m. 222–3° (Ni block). The Li deriv. of dibenzofuran and Br vapor give 40.5% of the *4-Br deriv.*, m. 70–1°; HNO_3 in AcOH gives the *7-NO_2 deriv.* (VII), m. 205°. 4-Iododibenzofuran gives 32.4% of the *7-NO_2 deriv.* (VIII), yellow, m. 223°. Reduction of VII with Pd catalyst (15 pounds H pressure) gives 40% of VI; VIII gives 32% of 3-nitrodibenzofuran. Me 4-dibenzofurancarboxylate and AcCl with $AlCl_3$ in CS_2 give 15.5% of *Me 2-acetyl-6-dibenzofurancarboxylate*, m. 174–5°; the free *acid*, m. 262–5°, is decarboxylated to 2-acetyldibenzofuran (IX). 3-Nitrodibenzofuran and AcCl with $AlCl_3$ in $PhNO_2$ give 93.5% of *2-acetyl-8-nitrodibenzofuran* (X), m. 212–13°; no reaction occurs in CS_2. Catalytic reduction of X gives the *7-NH_2 deriv.* (XI), m. 158–9°; *Ac deriv.*, m. 203° (*oxime*, m. 203°). Through the diazo reaction XI gives IX. Oxidation of X with CrO_3 in AcOH (heating 3 hrs.) gives 72% of *3-nitro-8-dibenzofurancarboxylic acid* (XII), decomps. 300°. Me 3-dibenzofurancarboxylate with HNO_3 gives 31.8% of *Me 2-nitro-7-dibenzofurancarboxylate* (XIII), m. 235.6°, and an ester, m. 202–3°, probably the Me ester of 3-nitro-7-dibenzofurancarboxylic acid. The free acid from XIII did not m. 330° and is decarboxylated to 2-nitrodibenzofuran VI and NH_4SCN in 95% AcOH at 1.3°, treated with Br in AcOH, give 43% of *3-amino-2-dibenzofuryl thiocyanate*, m. 175°; Pb tartrate gives a yellow color, refluxing with EtOH-HCl for 0.5 hr. gives *2-aminobenzofuro[2,3-f]benzothiazole*, m. 268.9° (*HCl salt*, decomps. above 300°). Dibenzofuran and AcCl with $AlCl_3$ in CS_2 give 46–57% of IX and 8% of the 2,8-di-Ac deriv. (XIV); with $PhNO_2$ the yield of IX is 40%; with Ac_2O there is a slightly higher yield of XV. IX and AcCl with $AlCl_3$ in CS_2 give 32% of XIV, m. 160°. Oxidation of XIV gives 2,8-dibenzofurandicarboxylic acid, which is also obtained in poor yield by carbonation of the di-Grignard reagent from 2,8-dibromofuran (XV) but is best prepd. from the di-Li compd. The *oxime* of IX m. 139–40°. XV and AcCl with $AlCl_3$ in CS_2 give 35% of the *3-Ac deriv.*, m. 157–7.5°; catalytic removal of the Br atoms gives 3-acetyldibenzofuran, m. 120–2°. Nitration of IX gives a NO_2 acid, m. 290°. Me 2-dibenzofurancarboxylate and HNO_3 give as 1 of the products the Me ester of XII, m. 239–40°. 2-Bromodibenzofuran and AcCl give 32% of the 8-Ac deriv., b. 205°, which is oxidized by NaOCl to 2-bromo-8-dibenzofurancarboxylic acid (XVI), m. 328°. Et 2-dibenzofurancarboxylate and Br in AcOH give 28% of the *Et ester* of XVI, m. 130°. IA and HNO_3 in AcOH at 90–5° (1.5 hrs.) give 47.5% of *1-bromo-3-nitro-4-methoxydibenzofuran*, m. 160–1°; *3-NH_2 deriv.*, m. 135–6° (*Ac deriv.*, m. 178–9°). Dibenzofuran and succinic anhydride with $AlCl_3$ in $C_2H_2Cl_4$ and $PhNO_2$ give 83% of *β-(2-dibenzofuroyl)propionic acid*, m. 185–6°; Clemmensen reduction in PhMe gives 83% of *β-(2-dibenzofuryl)-butyric acid*, m. 112–13°; 88% H_2SO_4 at room temp. for 15 min. gives 45% of *7-keto-7,8,9,10-tetrahydrobenzo[b]-naphtho[2,3-d]furan* (XVII), m. 137°; *oxime*, m. 212–13°; reduction of the oxime with 2% Na-Hg in abs. EtOH at 55–60° gives 54% of the *HCl salt*, m. 266–7°, of *7-amino-7,8,9,10-tetrahydrobenzo[b]naphtho[2,3-d]furan*. XVII, Me_2NH.HCl and trioxymethylene in AmOH, refluxed 5 min., give 14.3% of the *8-dimethylaminomethyl deriv.* of XVII; a longer reaction period did not improve the yield. IX and HCO_2NH_4 in AcOH give *2-α-aminoethyldibenzofuran-HCl*, m. 222–3°. The bromide from methyl-2-dibenzofurylcarbinol and Et_2NH give *2-α-diethylaminoethyldibenzofuran*, whose *picrate* m. 173–4°. IX, Me_2NH.HCl and trioxymethylene in abs. EtOH, heated 12 hrs. on the steam bath, give 74% of *2-β-dimethylaminopropionyldibenzofuran*, m. 88–9°; *HCl salt*, m. 194–5°. 3-Aminodibenzofuran and *p*-$MeC_6H_4SO_3Et$, heated 1 hr. at 175–85°, give 33% of *3-ethylaminodibenzofuran-HCl* (XVIII), m. 228–9° (decompn.); the free base m. 69–70°; HNO_2 gives *3-ethylnitrosoaminodibenzofuran*, bright orange, m. 136–7°; $SnCl_2$ and HCl give XVIII. VI with Ac_2O in a mixt. of 150 cc. AcOH and 200 cc. H_2O gives 97% of the mono-Ac deriv.; HNO_3 in AcOH gives 76% of the 2-NO_2 deriv.; reduction with $SnCl_2$ and HCl in AcOH gives 55% of 2-methyl-1-benzofuro[2,3-*f*]benzimidazole, m. 270°; HCl salt, m. above 335°. IVA with $SnCl_2$ in HCl-AcOH, refluxing 5.5 hrs., gives 72.5% of *2-methyl-5-methoxy-1-benzofuro[3,2-e]benzimidazole*, m. 222–2.5°; *HCl salt*, m. 306–7° (decompn.). 2-Acetyl-7-acetaminodibenzofuran and fuming HNO_3 in AcOH give 64% of the *8-NO_2 deriv.*, m. 270–1°; catalytic reduction with Raney Ni at 100° under a H pressure of 45 lbs. gives 55% of *2-methyl-8-acetyl-1-benzofuro[2,3-f]benzimidazole*, m. 298°; *HCl salt*, m. about 325° (decompn.). Dibenzofuran and BuLi in Et_2O, refluxed 4.5 hrs. in an atm. of N, cooled to 0–5° and treated with isoquinoline, give 11.3% of *1-(4-dibenzofuryl)isoquinoline*, m. 137–8°; the HCl salt is immediately hydrolyzed by H_2O. 4-Dibenzofurancarbonyl chloride and CH_2N_2 give a quant. yield of crude diazomethyl 4-dibenzofuryl ketone, m. 72–5°; 5 g. in 100 cc. dioxane, heated on the steam bath, treated with 25 cc. concd. NH_4OH and then with 5 cc. of 10% $AgNO_3$, gives 67% of *4-dibenzofurylacetamide*, m. 211–12°; refluxing with 15% NaOH for 5 hrs. gives 82% of *4-dibenzofurylacetic acid* (XIX), m. 213.5–14.5°. The acid chloride of XIX in Et_2O and an aq. soln. of 3,4-dimethoxy-α-aminoacetophenone-HCl with KOH give 57% of *3,4-Dimethoxy-α-(4-dibenzofurylacetamino)acetophenone*, m. 186.7°; 4-dibenzofurancarbonyl chloride gives *3,4-dimethoxy-α-(4-dibenzofuroylamino)acetophenone*, m. 178–9°. XIV. **Diazo coupling of 2-, 3- and 4-hydroxy compounds.** Henry Gilman and Marian Weston Van Ess. *Ibid.* 3146–8.—2-Hydroxydibenzofuran in KOH at 0°, treated dropwise with PhN_2Cl, gives the *1-benzeneazo deriv.* (I), red, m. 165.5–6°. *2-Benzeneazo-3-hydroxy analog* (II), golden brown, m. 177–8° (73% yield); *1-benzeneazo-4-hydroxy analog* (III), yellow-orange, m. 174–5°. The structures of these compds. follow from their conversion to the corresponding Br derivs. I in AcOH with $SnCl_2$ in HCl gives a quant. yield of the 1-NH_2 deriv. (IV); the HBr salt of IV in H_2O is gradually poured into a soln. of $NaNO_2$ and $CuSO_4$ in H_2O (both at 0°) and after 15 min. the diazo soln. is poured into CuBr and HBr is added, giving 1-bromo-2-hydroxydibenzofuran. In the same way II and III were converted to the known Br derivs. The non-isolation of any 4-benzeneazo deriv. in the prepn. of II indicates absence of any fixed bond structure in these simple types. XV. **1,4- and 1,4,6-Derivatives.** Henry Gilman and Lee C. Cheney. *Ibid.* 3149–56.—Incidental to studies concerned with the bridging of the 1- and 9-positions in dibenzofuran types, series of 1,4- and 1,4,6-derivs. have been synthesized. In these compds. the 4- and 4,6-substituents are strong *o,p*-directors. 4-Hydroxy-6-methoxydibenzofuran (I) with HBr in AcOH gives 91.6% of 4,6-dihydroxydibenzofuran (II), m. 200–2°. II (0.115 mole), 0.345 mole of Me_2SO_4, 39 ml. of 60% KOH and Me_2CO give a nearly quant. yield of *4,6-dimethoxydibenzofuran* (III), m. 128–9°; *picrate*, deep yellow, m. 161–2°. III and AcCl with $AlCl_3$ in $PhNO_2$ give 60% of the *1-Ac deriv.* (IV), m. 178.5–9.5°. The *oxime* of IV, m. 203–4°, with PCl_5 in C_6H_6 gives 76.4% of *1-acetamino-4,6-dimethoxydibenzofuran*, m. 244–5°; hydrolysis gives the HCl salt, m. 286–7°, of the 1-NH_2 deriv. (V) of III, m. 162–2.5°. I (4.28 g.) in 15 ml. 15% KOH and 385 ml. H_2O, treated with the PhN_2Cl from 0.02 mole $PhNH_2$ at 3°, gives 56.6% of *1-benzeneazo-4-hydroxy-6-methoxydibenzofuran*, rust-colored, m. 175°; Me_2SO_4 and KOH in Me_2CO give 88% of the *4,6-di-MeO deriv.*, deep orange, m. 170°; reduction gives 32.8% of V. 4-Methoxydibenzofuran (VI) and 10% excess of $(COCl)_2$ in $PhNO_2$, treated with 10% excess $AlCl_3$ at 0° and allowed to stand at room temp.

for 28 hrs., give a mixt. of 3 products; extn. of the amorphous product with 5% NaOH gives *4-methoxy-1-dibenzofurancarboxylic acid*, m. 276–7°; the alkali-insol. solid, extd. with AcOH, gives 18% of *bis(4-methoxy-1-dibenzofuryl) ketone*, m. 234°; the AcOH-insol. portion is *bi(4-methoxy-1-dibenzofuroyl)*, pale yellow, m. 329°, 34.6% yield. VI and $ClCH_2COCl$ with $AlCl_3$ in $PhNO_2$ give 53.2% of the *1-chloroacetyl deriv.*, m. 165–6°; $ClCOCO_2Et$ gives 43% of the *1-ethoxalyl deriv.*, m. 113°; hydrolysis with 15% NaOH gives *4-methoxy-1-dibenzofuryl-α-oxoacetic acid*, pale yellow, m. 187° (*semicarbazone*, m. 211.5–12° (decompn.)). III (4.86 g.) and $(COCl)_2$ with $AlCl_3$ in $PhNO_2$ give 0.37 g. 4,6-dimethoxy-1-dibenzofurancarboxylic acid, m. 297–8°; 10.4% of *bis(4,6-dimethoxy-1-benzofuryl) ketone*, m. 254–5°, sol. in AcOH, and 60.7% of *bi(4,6-dimethoxy-1-dibenzofuroyl)*, pale yellow, m. above 300°, insol. in AcOH. 3-Hydroxy-4-methoxydibenzofuran (VII) and HBr in AcOH give 88% of *3,4-dihydroxydibenzofuran* (VIII), m. 164–4.5°; *di-Ac deriv.*, m. 104–5°. VII and Me_2SO_4 with 10% NaOH give 81% of the *3,4-di-Me ether* (IX), m. 60–1°. IX and AcCl give 55.5% of the *1-Ac deriv.* (X), m. 90.5–1°. The *oxime* of X, m. 156–7°, is rearranged by PCl_5 in C_6H_6 to give 94% of *1-acetamino-3,4-dimethoxydibenzofuran*, m. 156–7°; hydrolysis gives *1-amino-3,4-dimethoxydibenzofuran*, m. 162.5–3°, which also results in 10% yield on heating the 1-Br deriv. of IX with concd. NH_4OH and CuBr for 14.5 hrs. at 220–30°. III (22.8 g.) in 600 ml. AcOH and 100 ml. of *M* Br soln. in AcOH give 73% of the *1-Br deriv.*, m. 152°, and 12% of a product m. 144–7°; III (3 g.) and 52.7 ml. of a 0.5 *M* Br-AcOH soln. give 74% of the *1,9-di-Br deriv.* (XI), m. 167–8°. II gives a nearly quant. yield of the *1,9-di-Br deriv.*, m. 239–40° (decompn.); Me_2SO_4 gives XI. I gives 58.6% of the *1,3-di-Br deriv.*, m. 177–8°; Me_2SO_4 gives the *1,3-di-Br deriv.* of III, m. 173.5–4°. IX forms 88.5% of the *1-Br deriv.*, m. 108°; VII yields 54.6% of the *1-Br deriv.*, m. 161–2°, which was also prepd. from 1-bromo-3-amino-4-methoxydibenzofuran through the diazo reaction in 21% yield. 4-Bromo-6-methoxydibenzofuran *(XII) and HI (d. 1.67) give 19% of the *6-HO analog*, m. 138–9°; $FeCl_3$ gives a green color. XII, CuBr and NH_4OH, heated in a steel bomb for 10 hrs. at 100° and for 8 hrs. at 215°, give 51% of the *IICl salt*, m. 235–6°, of *4-amino-6-methoxydibenzofuran*, m. 109°; HBr in AcOH gives the *6-HO analog*, m. 191.5–2.5°. II, $NaHSO_3$ and concd. NH_4OH, heated at 185–95° for 20 hrs., give 81% of *4,6-diaminodibenzofuran*, m. 152°; *IICl salt*, m. 298° (decompn.); *picrate*, red-brown, m. 213° (decompn.); *di-Ac deriv.*, m. 297–8°. *Di-Ac deriv.* of II, m. 177°. II and PhN_2Cl give a dark brown compd., m. 228° (decompn.), which is nearly pure *1,3,9-trisbenzeneazo deriv.*; Me_2SO_4 gives 77% of *1,3,9-trisbenzeneazo-4,6-dimethoxydibenzofuran*, red-orange, m. 191–3°. The 1-Ac deriv. of III, oxidized with I-KI in NaOH-dioxane, gives 55.2% of *4,6-dimethoxy-1-dibenzofurancarboxylic acid* (XIII), m. 297–8°; this also resulted from carbonation of the Grignard reagent of the 1-Br deriv. of II; *Me ester*, m. 163°. XIII gives an acid chloride, m. 147–50°; CH_2N_2 gives 21.2% of *diazomethyl 4,6-dimethoxy-1-dibenzofuryl ketone*, pale yellow, m. 151° (decompn.); heating the ketone with concd. NH_4OH and $AgNO_3$ in dioxane gives 52% of the *amide*, m. 210–11°, of *4,6-dimethoxy-1-dibenzofurylacetic acid*, m. 205.5–6.5°. 3-Aminodibenzofuran, diazotized and reduced with $SnCl_2$, gives 87.3% of the *IICl salt*, m. 242–3°, of *3-hydrazinodibenzofuran*, pale yellow, m. 174–5°, which turns orange in the atm. 4-Aminodibenzofuran in abs. EtOH, reduced by Na in a N atm., gives 62% of *1,2,3,4-tetrahydro-6-aminodibenzofuran*, which is an oil at 0°; *HCl salt*, pink, m. 228° (decompn.); the diazo soln. with β-$C_{10}H_7OH$ gives a quant. yield of a brilliant carmine red dye, m. 199–201°. C. J. West

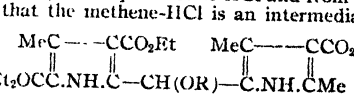
Dibenzofuran. XVI. The two-stage metalation of 2-bromodibenzofuran. Henry Gilman, Wright Langham and H. B. Willis. *J. Am. Chem. Soc.* **62**, 346–8(1940); cf. preceding abstr.—Refluxing 0.0081 mole of 2-bromodibenzofuran (I) in 25 cc. C_6H_6 and 0.009 mole of BuLi in 25 cc. Et_2O for 30 min. and pouring upon dry-ice and ether give 87.3% of 2-dibenzofurancarboxylic acid (II); the Me ester m. 82–3°. If to the above reaction there is added after 15 min. 0.032 mole I and the product is carbonated after refluxing for 6 hrs. only 2-bromo-4-dibenzofurancarboxylic acid is isolated. With 3 equivs. of BuLi to 1 of I in a 1:1 Et_2O-C_6H_6 mixt. heated for 6 hrs. at 50°, the yield of II is 64%. First there is a halogen-metal interconversion and the organometallic compd. formed in this manner then metalates the original halogenated ether; the interconversion reaction is more rapid. *p*-BrC_6H_4OMe and BuLi, heated at 34° for 20 hrs. and then carbonated, give 10% of *p*-$MeOC_6H_4CO_2H$ and 10% of 5,2-$Br(MeO)C_6H_3CO_2H$ (III); with a more concd. soln. which permits refluxing at 50° the yield of III is 28%; with 2 equivs. of *p*-BrC_6H_4OMe the yield of III was about 50%; other expts. are reported. With *p*-IC_6H_4OMe BuLi gives *p*-$MeOC_6H_4CO_2H$ predominantly if not exclusively in 30 min., whereas after 6 hrs. only 5,2-$I(MeO)C_6H_3CO_2H$ is formed. **XVII. The reaction of bromo ethers with butyllithium.** Henry Gilman, Jack Swislowsky and George E. Brown. *Ibid.* 348–50.—1-Bromo-2-methoxydibenzofuran (I) and BuLi in Et_2O-C_6H_6 give 47% of 2-methoxy-1-dibenzofurancarboxylic acid (II); the 4-MeO isomer of I gives 68.5% of the 4-MeO isomer of II. 4-Bromo-1-dibenzofurancarboxylic acid and CH_2N_2 give a quant. yield of *Me 4-methoxy-1-dibenzofurancarboxylate*, m. 125°. 3-Bromo-2-methoxydibenzofuran and 3 moles of BuLi give 40.5% of 2-methoxy-3-dibenzofurancarboxylic acid; with 1.5 moles BuLi the yield of acid is 24.5%. 6-Bromo-4-methoxydibenzofuran and BuLi give 57.4% of 4-methoxy-6-dibenzofurancarboxylic acid. 1-Bromo-3,4-dimethoxydibenzofuran and BuLi give 54% of *3,4-dimethoxy-1-dibenzofurancarboxylic acid* (III), m. 236°, identical with that prepd. by oxidation of 1-acetyl-3,4-dimethoxydibenzofuran; the *Me ester* m. 78°. 1-Bromo-4,6-dimethoxydibenzofuran and BuLi give 60% of the 4,6-di-MeO isomer of III. 1,9-Dibromo-2,8-dimethoxydibenzofuran (IV) and BuLi give 66.6% of 2,8-dimethoxy-1,9-dibenzofurandicarboxylic acid, m. 270–1° (Me ester, m. 128–9°). The 3,7-di-Br isomer of IV gives 17.5% of *2,8-dimethoxy-3,7-dibenzofurandicarboxylic acid*, m. 290° (decompn.); *Me ester*, m. 183–4°. C. J. West



Synthesis of a high-molecular hydroxymethylfurfural derivative. Tosinori Iseki and Tukouru Sugiura. *J. Biochem.* (Japan) **30**, 113–18(1939).—According to modern conceptions, not all polyoses are made up of monose residues attached to each other in long chains but consist of relatively simple units, e. g., anhydrides. The synthesis of high-mol. compds. by the polymerization of such anhydrides of low mol. wt. should be of value in complementing the knowledge gained in this field by degradation expts. I. and S. have found that a carbohydrate of high mol. wt. can be prepd. with relative ease from hydroxymethylfurfural (I), a furanose anhydride. When bis(5-formylfurfuryl) ether, $[O.C(CHO):CH.CH.CCH_2]_2O$ (II), which is easily prepd. by heating I, is fed to animals, more than 50% is recovered in the urine as bis(5-carboxyfurfuryl) ether (III) (*C. A.* **27**, 2953). The same acid, m. 209–10°, is obtained synthetically in more than 85% yield from II with NH_3-$AgNO_3$ in the presence of NaOH (Einhorn, *Ber.* **26**, 454(1893)). When its dichloride in pyridine is poured into water there seps. a yellowish mass which becomes solid on washing. Analysis indicates the product (IV) is a condensed acid anhydride formed from 4 mols. of the chloride by elimination of HCl and it is assumed to be *tetra(pyromucic anhydride-5-methyl) ether*, $O(CO.R.CH_2.O.CH_2.R.CO.O.CO.R.CH_2.O.CH_2.R.CO)_2O$ (R = —C.O.C(CH)=CH—). *Mono-Me ester* of III, m. 144–6°, is obtained in 0.69 g. yield, together with 0.74 g. di-Me ester and 0.26 g. free III, from 2 g. III refluxed 4 hrs. in 25 cc. MeOH and 0.5 cc. concd. H_2SO_4. *Dichloride* (100% from III refluxed in $SOCl_2$), m. 98–9°. *Di-Me ester* (100% from the dichloride boiled 2–3 min. in 3–4 parts MeOH), m. 154°; *di-Et ester*, m. 71°; *bis(2-chloroethyl) ester* (3 g. from 3 g. dichloride heated 1.5 hrs. at 120–5° with 10 g.

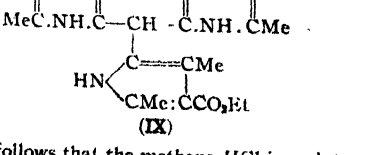
$ClCH_2CH_2OH$), m. 78–9°. IV (0.52 g. from 0.909 g. dichloride in the suitable amt. of acetone treated dropwise with 0.48 cc. pyridine, poured with stirring into ice water and allowed to stand 1 day at 0°), m. 165–7°, mol. wt. (Rast) 960, 1033. C. A. R.

Decomposition of 2-furaldehyde in the presence of mineral acids. A. I. Lazarev. *Org. Chem. Ind.* (U. S. S. R.) 6, 258–9(1939).—The decompn. of 2-furaldehyde (I) by dil. acids and electrolytes was studied as a possible cause of the poor yields of I obtained in the com. production by hydrolysis of cellulosic materials, yielding about 50% I instead of the theoretically possible 72.7% based on the content of pentosans. The comparative tests consisted in refluxing 1–5 hrs. 10 ml. of 2% I with and without the addns. of 25 ml. of 5–15% HCl, 20–35% H_2SO_4, 20% NaCl and 5% $CaCl_2$. The max. rate of 30% decompn. is effected by 15% HCl and 35% H_2SO_4 in the 1st hr. The decompn. rate is then retarded, with a max. loss of 82.4% I in 5 hrs. NaCl and $CaCl_2$ decompd. 4.2% and 3.5% I in the 1st hr. and 5.2% and 4.5% in 5 hrs., resp. Since in the com. production I is removed from the reaction zone within a few min., it is evident that the low I yields are not caused chiefly by the destructive action of acids and electrolytes. The investigation is being continued. C. B.



Exchange of hydrogen atoms between pyrrole, indole and their methylene derivatives and water. VI. Exchange of hydrogen atom between α-methyl-, β-methyl- and α,β-dimethylindole and water. Masao Koizumi. *Bull. Chem. Soc. Japan* 14, 453–61(1939); cf. *C. A.* 33, 2022⁸.—Exchange of H was studied between dil. D_2O and α-methyl- (I), β-methyl- (II) and α,β-dimethylindole (III) and at pH values from −0.5 to 7.0. With I, 2 H atoms exchange under all conditions. One of these is the H atom bound to N and the other is most probably the H atom bound to C in the β-position of the pyrrole ring. For II, exchange is difficult even in strongly acid soln. except for the H atom bound to N. Similar results are obtained for III, no further exchange being observed in 3 *N* HCl after 20 hrs. heating at 60°. The results are compared with those previously obtained for unsubstituted indoles. **VII. Exchange of hydrogen atom between indole, indene and water in alkaline solution.** *Ibid.* 491–500.—Both the H atom bound to N and that bound to C in the pyrrole ring exchange in indole in alk. soln. The rate of exchange is much slower than in acid soln. There is no evidence for step-wise exchange. The behavior of indene is similar. The exchange mechanism in alk. soln. is a simple acid-base catalytic reaction and is quite different from that in acid soln. G. M. Murphy

Pyrrole series. IV. A dipyrrylmethene which is a true intermediate in its own formation. Joseph H. Paden, Alsoph H. Corwin and Wm. A. Bailey, Jr. *J. Am. Chem. Soc.* 62, 418–24(1940); cf. *C. A.* 32, 1557.—In part III it was demonstrated that a step-wise synthesis of 3,5,4′-tricarbethoxy-4,3′,5′-trimethyldipyrrylmethane (I) could be achieved in which a tripyrrylmethane (II, R = H) was an intermediate if 2 moles of 2,4-dimethyl-3-carbethoxypyrrole (III) were used to 1 mole of 2-formyl-3,5-dicarbethoxy-4-methylpyrrole (IV) and the resulting tripyrrylmethane was cleaved subsequently by the addn. of another mole of IV: IV + 2 III → II; II + IV + 2HCl → 2 I. In previous communications on the mechanism of the aldehyde synthesis of dipyrrylmethenes, it has been assumed arbitrarily that dipyrrylcarbinols are intermediate in the various cleavages. While it still seems necessary to retain the assumption of a carbinol as the 1st reaction product of aldehyde and α-free pyrrole, it is now unnecessary to assume any chem. intermediate between tripyrrylmethanes and dipyrrylmethenes, either in cleavage or in recombination, since it can be demonstrated that the methenes themselves are capable of combining with α-free pyrroles to form tripyrrylmethanes. I (0.4 g.) in 20 cc. dioxane (V) (dried over 40% Na-Hg and distd. over Na) and 0.184 g. III, shaken for 50 sec. and then poured into 200 cc. ice and H_2O, give 0.54 g. (95%) of II, m. 190.5–1.5°. The distn. of V is important. Various other conditions for the formation of II are given. I and 1,2,4-trimethyl-3-carbethoxypyrrole (VI) in V contg. a little KHSO₄ for 3.5 min. give 91% of the *N*-Me deriv. of II (II, R = Me), m. 155–6°; after a reaction time of 1 min. the yield is only 40%; a reaction mixt. without $KHSO_4$ does not proceed appreciably after 100 min. Since the reaction of I and III is complete in 30 sec., the *N*-Me group on an α-free pyrrole decreases its speed of combination with a methene. A close scrutiny of the course of the reaction between a carbinol Me ether (VII, R = Me)



(II)

and an α-free pyrrole or alternatively between II and an α-free pyrrole, both reactions in the presence of HCl, leads to the conclusion that the reaction to form methene-HCl and that to form tripyrrylmethane are not competing reactions but are consecutive. I in abs. ether, treated with HCl for 1 min. at 0°, gives 96% of the HCl salt; VII (R = Me) in ether gives 93% of its HCl salt; the pptn. being instantaneous. I in 75 cc. ether and IV in ether satd. with HCl give a ppt. on mixing which dissolves in 5 sec.; shaking for 2 min. and pouring into 5% NaOH gives 91.5% of II (R = H); the same reaction occurs when II is added to I and HCl; the yield of II is 90% in V; the yield of II in ether may be increased to 97.5% by bubbling in HCl for only 5 sec. and then evapg. the ether on the steam bath. I (0.4 g.) in 100 cc. ether, treated with 0.181 g. VI, then with HCl for 2 min. and the mixt. shaken for 3 min. at room temp., give 1.1% of I.HCl and 88% of II (R = Me); in another expt. the reagents were dissolved in part of the ether and the other part was satd. with HCl and then added all at once; the yield of I.HCl is 11%; of II (R = Me), 72%. VII (R = Me) in hexane gives 73% of I.HCl in 2 min.; on drawing air through the filtrate for a few min., 24% of II (R = Me) is formed; the difference is probably due to the insoly. of the I.HCl in the hexane. These observations show that the methene-HCl is an intermediate in the formation of tripyrrylmethane from VII (R = Me) in the presence of HCl and from them it is inferred that the methene-HCl is an intermediate in the

(VII)

formation of the tripyrrylmethane from the free carbinol, a material which has so far resisted all attempts at isolation. IV and III in ether at 5°, treated with HCl for 3 min. and poured into cold 5% NaOH, give 44.5% IV and 47% of II (R = H); as the soln. of IV and III used for the synthesis of I in the presence of HCl becomes increasingly dil. the time of initial appearance of a ppt. of the methene is progressively delayed, as is the time required for obtaining the max. yield; the above facts demonstrate that the tripyrrylmethane is an intermediate in the formation of the methene-HCl; since the methene-HCl is an intermediate in the formation of tripyrrylmethane from the

(IX)

carbinol, it follows that the methene-HCl is an intermediate in its own formation. Using $KHSO_4$ as the catalyst in place of HCl, the reaction of I and III to give II (R = H) is complete in 15 sec., whereas that of IV is not complete in 1 hr.; under the same conditions no appreciable cleavage of II (R = H) by IV took place even when the mixt.

was refluxed for 0.5 hr. 3,5,3',5'-Tetramethyl-4,4'-dicarbethoxydipyrrylmethane (VIII) and III in V with $KHSO_4$ give after 155 min. 91% of IX; with dioxane and HCl only the HCl salt of VIII could be isolated. The 5-formyl deriv. of III and III do not condense in V with $KHSO_4$. II (R = H) in ether, treated with HCl for 10 min. and then allowed to stand for 1 yr., gives the HCl salt of VIII and probably 4-methyl-3,5-dicarbethoxypyrrole; the latter could not be isolated. C. J. West

The reduction potential of some pyrrole ketones. I. Methyl pyrryl ketones (acetylpyrroles). Giuseppe Scaranielli. *Boll. sci. facoltà chim. ind., Bologna* **1940**, No. 1-2, 49-54; cf. Bonino and S., *C. A.* **30**, 8208[2].—The reduction potential of the CO group was studied in 2-acetylpyrrole, *N*-acetylpyrrole, 2,3,5-trimethyl-4-acetylpyrrole and 2,4-dimethyl-5-carbethoxy-3-acetylpyrrole. The potentials were measured by the polarographic method with a Hg-drop cathode. The measurements were made with 0.1 *N* NH_4Cl and HCl. The exptl. results, which are tabulated and discussed, show that the CO group in the α-position is reduced easily whereas the CO group in the β-position is not reduced under the same exptl. conditions. **II. 2,5-Diacetylpyrrole.** *Ibid.* 59-60.—Expts. with 2,5-diacetylpyrrole similar to those described above for various acetylpyrroles showed that the diacetylpyrrole exhibited on reduction 2 polarographic waves, of which the 2nd corresponded to a reduction potential which was practically identical with that detd. for 2-acetylpyrrole, whereas the 1st wave corresponded to a lower reduction potential. This phenomenon indicates a difference in the structure of the Ac groups at positions 2 and 5, the possible reasons for which are discussed. Further studies are in progress to clarify the polarographic behavior of the diacetylpyrrole. Dora Stern

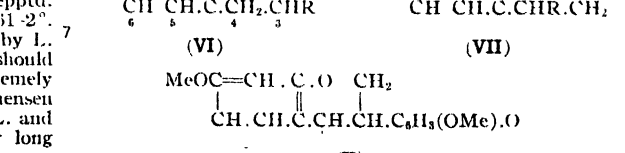
Naphthoylenediethoxybenzimidazole and the structure of Indanthrene Red-Brown 5 RF. I. V. Grachev. *Org. Chem. Ind.* (U. S. S. R.) **6**, 304 6(1939).—According to Fierz-David (*Kunstliche org. Farbstoffe, Ergänzungsband, C. A.* **30**, 2012[7]) and Jones (*C. A.* **30**, 7347[4]), *Indanthrene Red-Brown 5 RF* (I. G.) (I) is *naphthoylenediethoxybenzimidazole* (II) obtained from $1,4,5,8\text{-}C_{10}H_4(CO_2H)_4$ by condensation (1) with $4,1,2\text{-}EtOC_6H_3(NH_2)_2$ (Ger. pat. 457,980) and (2) with $3,4\text{-}O_2N(H_2N)C_6H_3OEt$ with subsequent reduction and ring-closure (Ger. pat. 456,236). Comparative tinctorial tests and spectrophotometric measurements of com. I and II, prepd. by the 2 methods, as well as their cis and trans isomers, showed that I and II are different compds. Study of the I structure is being continued. C. B.

Action of bromine on certain thioamides. David E. Worrall and Arthur W. Phillips. *J. Am. Chem. Soc.* **62**, 424-5(1940); cf. *C. A.* **34**, 766[2].—Addn. of 10 g. of PhN:C(SH)CH$(CO_2Et)_2$ in AcOH to a mol. equiv. of Br in AcOH gives approx. 5 g. of *di-Et benzothiazole-2-malonate* (I), m. 138-9°; I gives a salt with EtOH-KOH, which regenerates I with HCl; it acts as an enol with MeMgI; heating I with concd. HCl for 2 hrs. gives 2-methylbenzothiazole (II). PhNCS and CH_2Ac_2 give *2-benzothiazolylacetylacetone*, m. 155°; hot alkali rapidly gives II; acid reacts more slowly. C. J. West

Synthesis of 4,5'-bithiazolyl and 4-(5-imidazolyl)-thiazole derivatives. Eiji Ochiai, Yuzo Tamamusi and Huzio Nagasawa. *Ber.* **73B**, 28-32(1940).—2-Hydroxy-4-methyl-5-acetylthiazole (I) and *4-methyl-5-acetylimidazole* (II) are now readily available. I was prepd. as previously described (*C. A.* **33**, 7782[9]) and II by the O. and Ikuma method (*C. A.* **30**, 5218[6]) by the following series of reactions: $Ac_2C{:}NOH$ (+ H) → $Ac_2CHNH_2.HCl$ (+ KSCN) → MeC:CAc.NH.C(SH):N (III) (+ HNO_3) → II. I and II are converted by Br in $CHCl_3$ or AcOH into the bromoacetyl analogs which with thiourea, MeCSNH_2 or $HCSNH_2$ give the corresponding bithiazolyls or imidazolylthiazoles. In this condensation reaction the +M effect of the HO or NH in the hydroxythiazole or imidazole must result in a diminution of the activity of the C:O in the $COCH_2Br$ (Ingold, *C. A.* **29**, 1057[3]) group and the yields were by no means satisfactory, especially in the reactions with the unstable $HCSNH_2$. *2-Mercapto-4-methyl-5-acetylimidazole* (III) (10 g. from 10 g. $Ac_2C{:}NOH$ hydrogenated with Pd and H in *N* HCl, filtered from the catalyst, treated with 16 g. KSCN in concd. aq. soln., heated 10 min. on the water bath and allowed to stand overnight), decomps. 308°. Boiled a few min. in 10% HNO_3, III gives the *nitrate*, m. 200°, of II, m. 151°; *semicarbazone*, m. 212°. *4-Methyl-5-bromoacetylimidazole* (IV) was isolated as the *HBr salt*, decomps. 223°. *4-(4-Methyl-5-imidazolyl)thiazole*, from IV and $HCSNH_2$ hydrate in MeOH on the water bath, was isolated as the *picrate*, m. 178°; *2-amino deriv.*, from IV and thiourea, decomps. 210° (*di-HCl salt*, decomps. 253°; *Ac deriv.*, decomps. 315°); *2-Me deriv.* (0.5 g. from 1.3 g. IV and 0.5 g. $MeCSNH_2$), m. 183° (*HCl salt*, m. 225°; *picrate*, m. 205°). *2-Hydroxy-4-methyl-5-bromoacetylthiazole* (V), m. 167°. *2-Amino-2'-hydroxy-4'-methyl-4,5'-bithiazolyl*, decomps. 225°; *HCl salt*, m. 280-2°; *Ac deriv.*, decomps. above 335°. *2'-Hydroxy-4'-methyl-4,5'-bithiazolyl*, m. 184.5°; *2-Me deriv.* (0.3 g. from 0.4 g. V and 0.15 g. $MeCSNH_2$), m. 178°. C. A. R.

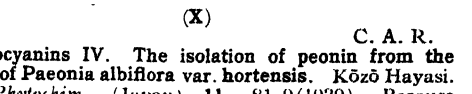
Resonance and the chemistry of histidine. Terrell L. Hill and Gerald E. K. Branch. *Science* **91**, 145-6(1940).—Certain chem. characteristics of histidine are explained by a consideration of its 15 principal forms in resonance, which can be classified into 4 groups. The chain N does not participate in the resonance of the ring and has the usual α-NH_2 group basicity (pK_b 4.85). The secondary amine N of the ring is not quite 0.25 double bonded on either side and is thus very weakly basic and abnormally acid. The third N is 0.3 double bonded on one side and 0.5 on the other; it is much more basic (pK_b 7.97) than the N of pyridine. D. S. Searle

An addition compound of histidine. W. W. Johnston and M. L. Johnston. *J. Fisheries Research Board Can.* **4**, 363-6(1939).—A histidine salt was obtained by extg. the minced muscle of tuna or mackerel with water at 80°, concg. the ext. to 0.1 its vol. at 80°, adding HCl to pH 3 and adding $HgCl_2$. NaOH was added to the filtrate to pH 8 and the resulting ppt. washed, suspended in water and treated with H_2S. The filtrate from this pptn. was freed of H_2S by aeration, $AgNO_3$ added, the ppt. removed and $Ba(OH)_2$ added to the filtrate until it was strongly alk., the soln. concd. and allowed to stand overnight. The resulting crystals, after recrystn. twice from water and once from alc., m. 276-7° (decompn.). Analyses for C, H, N, Ba and NO_3 indicate the salt to contain 2 mols. of histidine nitrate and 1 Ba atom. The same salt was also prepd. from histidine-2HCl. W. G. R.



Rottlerin. IV. Derivatives of isorottlerin. Ravi Sarup Jalota, Kartar Singh Narang and Jnanendra Nath Rây. *J. Indian Chem. Soc.* **16**, 405-9(1939).—Narang, Rây and Roy (*C. A.* **32**, 1099[8]) showed the presence of a 2nd yellow coloring matter (I), m. 181°, in Kamala powder. The mother liquor from the recrystn. of rottlerin (II) from toluene was concd. and 15 g. of the residue was treated with 150 cc. ether. The insol. crude I was recrystd. from a mixt. of MeOH and EtOAc. I (85 g.) in 250 cc. ether was chromatographed on an Al_2O_3 column. Elution of the 2nd zone with alc. ether gave I, $C_{31}H_{30}O_8$. II (5 g.) in 250 cc. of 90% alc. was heated for 7 hrs. with 15 cc. of HCl (d. 1.15). After standing overnight and filtering, the filtrate was dild. The pale yellow product was crystd. from ether, yielding I, identical with the isorottlerin described by Brockmann and Maier (*C. A.* **32**, 8419[7]); *Me ether* (III), m. 135-8°. A mixt. of 0.15 g. of piperonal and 0.6 g. III in 8 cc. alc. was refluxed for 2 min. with 1 mol. of 10% NaOH, yielding a *piperonylidene deriv.* (IV), m. 147°, in rectangular plates from alc. Oxidation of 0.5 g. III in 90 cc. MeOH by warming at 50° for 30 min. with 3 cc. of 8% NaOH and 4 cc. of 30% H_2O_2 gave *isorottlerin Me ether oxide*, m. 120-2°, decompg. with evolution of BzH on heating above 120°. Catalytic reduction of I produced pale yellow needles of *dihydroisorottlerin*, m. 225-8°; *Me ether* (V), m. 209°. Addn. of 0.5 g. $NaNO_2$ to 0.5 g. III in 7.5 cc. AcOH at 30° gave yellow prisms of *isorottlerin Me ether nitrosite*, m. 194-7° (decompn.), unchanged on catalytic hydrogenation but giving off BzH

on heating or on treatment with alkali. Reduction of both III and V with Zn dust and AcOH produced a white *solid*, m. 162–4°, whereas a similar reduction of rottlerin Me ether gave a *substance*, by catalytic hydrogenation, pyridine, nor oxidized with group has been created in the process of reduction and the double bond in the group PhCH:CHCO has been affected. The results demonstrate the invalidity of the rottlerin formula proposed by B. and M. and by Robertson (*C. A.* **32**, 4555[8]). C. R. Addinall



Spirochromans. Joseph B. Niederl and Richard H. Nagel. *J. Am. Chem. Soc.* **62**, 324–5(1940).—Condensation of 1 mole of *m*-EtC_6H_4OH and 1.5 moles of Me_2CO by passing dry HCl into the mixt. at room temp. for 6 hrs. and allowing it to stand 2 weeks gives about 80 g. of the *dimeric methovinylethylphenol*, b_{12} 200 7°, a viscous yellow liquid with a thymol-like odor; heating 10 g. with 5 drops conc'd. H_2SO_4 for 0.5 min. gives a nearly quant. yield of *4,4,4',4' - tetramethyl - 7,7' - diethylbis - 2,2'-spirochroman* (I), m. 114°; the yellow *tetra-NO_2 derv.* (II) m. 246 8°. Condensation of *m*-EtC_6H_4OH and phorone gives a I m. 146°; conc'd. HNO_3 gives II. It was possible to obtain crystn. by seeding a melt of the Me_2CO compd. crystals with a phorone compd. crystal and vice versa; this would seem to indicate a case of dimorphism. No depression in m. p. was observed with an equal mixt. of the 2 forms of I. C. J. West

The constituents of red sandalwood. I. Constitution of homopterocarpin. Ernst Spath and Josef Schlager. *Ber.* **73B**, 1–12(1940).—The finely grated wood (1870 g.) was extd. with ether and 1% aq. KOH was dropped through the ether ext. to remove the pigments and other compds. The concd. ether soln. on cautious addn. of petr. ether yielded crystals consisting chiefly of pterocarpin, m. 165°, the filtrate from which, on evapn. and alternate crystn. from MeOH and petr. ether, gave 11 g. of homopterocarpin (I), m. 88–9° and having the compn., $C_{17}H_{16}O_4$, assigned to it by earlier workers. In conc'd. H_2SO_4 I gives a red color and it cannot be recovered by dilu. with water. It is unchanged by distn. with Pd under 1 mm. Dehydrogenation with Se gives a red oil from which no homogeneous product can be isolated. It is quite stable toward $KMnO_4$ in acetone; only after standing several days can any reaction be observed. On hydrogenation with Pd sponge in AcOH it takes up 2 atoms H to form the dihydro compd. (II), m. 156–7°, $[\alpha]_D^{18.8}$ −6.0° ($CHCl_3$). As found by Leonhardt and Oechler (*C. A.* **30**, 1372[1]), in this hydrogenation no aliphatic double bond is satd. but an O bridge is ruptured. While I is insol. in dil. aq. alkalies, II is sol. and is repptd. by CO_2. With CH_2N_2 II gives a Me ether (III), m. 61–2°. That I does not contain a CO group, as assumed by L. and O., is indicated by some reactions of II, which should still contain any CO group present in I. II is extremely resistant to reduction by Na and alc. or by the Clemmensen method. It is likewise unchanged by MeMgBr. L. and O.'s dinitrophenylhydrazone is formed only after long boiling and is possibly the result of an oxidation process. In addn., further expts. completely excluded the presence of a CO group. PCl_5 with II gave an amorphous product. Oxidation of II with $KMnO_4$ in weakly alk. soln. and purification of the product through the Me ester, $b_{0.01}$ 160–70° (air bath temp.), gave 2,5-$HO_2C(MeO)C_6H_3O$-CH_2CO_2H (IV), $b_{0.02}$ 210–20° (air bath temp.), identical (mixed m. p.) with a synthetic product. $KMnO_4$ oxidation of III gave a little 2,5-$(MeO)_2C_6H_3CO_2H$ (V). These results show clearly that the 2 MeO groups in I are on different benzene nuclei, contrary to the conclusion of Dieterle and Leonhardt (*C. A.* **23**, 2245). The 2 oxidation products account for all of the C and O atoms of I. Two of the O atoms are present as MeO groups, 1 in the ether grouping of the OCH_2CO_2H residue found in IV, and the 4th, which after hydrogenation is present in II as a phenolic HO group, must be present in I in an O bridge union, leaving none for the CO group assumed by L. and O. Consideration of all the known facts leaves VI and VII (R = 2',4'-HO(MeO)C_6H_3) as the only possible formulas for II. The possibility that V is formed by elimination of CO_2 from IV and both products are therefore formed by oxidation of the same part of the mol. is ex-

between VI and VII the synthesis of the *Me ether* (VIII) of VI was undertaken for comparison with III. *2,4-Dihydroxyphenyl 2,4-dimethoxybenzyl ketone*, m. 155–6°, obtained in 0.75 g. yield by condensation of 8 g. 2,4-$(MeO)_2C_6H_3CH_2CN$ with *m*-$C_6H_4(OH)_2$ by means of anhyd. $ZnCl_2$ and HCl gas in boiling ether, was readily converted (yield, almost quant.) with CH_2N_2 into a *mono-Me ether*, m. 114 15°, 0.62 g. of which, condensed with HCO_2Me and Na at 20°, gave 0.25 g. *7-methoxy-2',4'-dimethoxyisoflavone*, $MeOC_6H_3.O.CH:CR'.CO$ (R' = 2,4-$(MeO)_2C_6H_3$) (IX), m. 148 9°. Catalytic hydrogenation of IX with Pd sponge in AcOH converted the CO group to CH_2 and satd. the double bond of the pyrone ring to give VIII, which m. 88–9°. That VIII has not the same m. p. as III is not proof that the 2 compds. do not have the same structure, however, for the III derived from natural I is optically active while the synthetic VIII is a racemate. Numerous attempts to racemize III by heating in evacuated tubes (e. g., 24 hrs. at 240°) were unsuccessful. However, III with CrO_3 gave a *ketone* which, after repeated distn. in a high vacuum, m. 111 12° and was optically inactive, and hydrogenation with Pd sponge in AcOH yielded a compd., m. 90°, identical (mixed m. p.) with VIII. Hence III indubitably has the same structure as VIII and II itself has the structure VI. That the free HO group is in the 2'-position has not been proved, to be sure, but if it were in the 4'-position it would be necessary to assume in I an O bridge extending to the 4'-position, for which there is no analogy. In deducing the structure of I itself from these facts it must be remembered that on catalytic hydrogenation under mild conditions an O ring in I is opened with formation of VI. Since in I there is no free phenolic HO group, 1 of the points of attachment of the O bridge must be at the 2'-position of the benzene residue R, and as the bridge is so readily ruptured by mild catalytic hydrogenation the other point of attachment can hardly be on an aromatic nucleus but is more likely on an aliphatic complex. Of the possible structures for I fulfilling these conditions preference given to X.

Anthocyanins IV. The isolation of peonin from the flowers of Paeonia albiflora var. hortensis. Kōzō Hayasi. *Acta Phytochim.* (Japan) **11**, 81–9(1939).—Because Willstätter had not designated the variety of peony from which he obtained peonin (I), H. isolated, separately, the pigment from 3 cultivated varieties; "Iko" (II) a dark red, "Hatu-garasu" (III) a red and "Deuda-no-Iro" (IV) a violet-spotted red. The cleaned fresh petals were extd. with 1% MeOH-HCl with cooling and the ext. and washings were conc'd. by a low-pressure distn. below 40°, with conc'd. H_2SO_4 in the receiver. Evapn. was so rapid that the soln. was cooled to below 10°. The concentrate was washed with ether and kept for some time, up to 2 weeks, at about 0°, whereupon the amorphous pigment which first sepd. became cryst. The percentages of I, found in all the varieties, were, in II, 0.115; III, 0.099; IV, 0.030. The crude I was crystd. from 2% aq. HCl. The air-dried sample (5 H_2O) m. 161–2°, a water-free

one at 177° (decompn.). The ax. distribution value between iso-AmOH and 0.05% HCl was 2.80. An absorption spectrum curve is given. The identity of the pigment as I was established by oxidation with H_2O_2, the formation of glucose phenylosazone (2 mols.) and the formation, on acid hydrolysis, of peonidin. The ether washings from III yielded crystals of kaempferol, identified by conversion to the tetraacetate, while II and IV yielded datiscetin. These flavone derivs. probably function as co-pigments. V. **The pigments of the berries of Fatsia japonica.** *Ibid.* 91–108.—Berries of *Fatsia japonica* gathered in Tokyo were pressed and the juice discarded. The skins were sepd. from the seeds and some resinous material by rubbing in H_2O. After partial drying by pressing, the skins (about 25% of the original berry material) were extd. with HOAc at room temp. for 3 days. The pigment was slowly pptd. as a thick sirup by addn. of 3 vols. of ether. The crude pigment was freed from some waxy material by soln. in 1% MeOH-HCl and repptn. by 3 vols. of ether. By repeating essentially the same process the ppt. finally adhered to the glass. Further purification was made difficult by the presence of resinous waxy matter. Ultimately a cryst. picrate was obtained by soln. of the ppt. in cold satd. aq. picric acid and subsequent standing at 0°. The yield of picrate was somewhat less than 5%. The air-dried substance contained 6.5 mols. of H_2O which it lost at 100°. By soln. in 3% MeOH-HCl and pptn. by 3 vols. of ether the picrate was converted into a crude chloride. The yield was about 0.18%. A pure sample was obtained by dissolving this material in 38% HCl and allowing it to stand at 0° overnight. Longer standing caused hydrolysis. Since 10% NaOH did not decomp. the pigment, no org. acid is attached to any part of the mol. The air-dried chloride, contg. 6.5 mols. H_2O, sintered at 185° and decompd. 191–2°. It gave no test for OMe. By standing a month it lost 4 mols. H_2O. The remaining H_2O was eliminated by drying at 100°. Qualitatively the pigment was shown to be identical with idein isolated from cranberries. Its distribution value between HCl and AmOH was 14.93. On acid hydrolysis it yielded cyanidin and galactose; the former, subjected briefly to alkali fusion, gave phloroglucinol and protocatechuic acid. After methylation with Me_2SO_4 in H the aglucon yielded veratric acid. The conclusions concerning the nature of the pigment, idein, 3-galactosidylcyanidin chloride, chemically arrived at, were confirmed by absorption spectra. A small amt. of the flavone deriv. quercetin was also present in the berries. This was isolated by extg. the fruit with 1% MeOH-HCl and by pptg. the flavone and anthocyanin as Pb salts. Ten % MeOH-HCl with these yielded a soln. of the pigments from which the red one was pptd. by 3 vols. ether. By alc. and H_2O the flavanol was finally obtained in a slightly impure state and yielded a penta-Ac deriv. which proved to be that of quercetin.

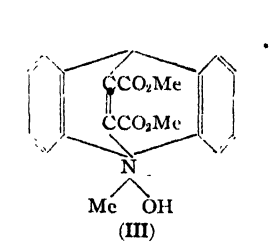
G. A. Hill

Pyridine series. I. Attempt to synthesize 2-methyl-4-ethylpyridine. Rafat Husain Siddiqui. *J. Indian Chem. Soc.* **16**, 410–14(1939).—An attempt has been made to synthesize 2-methyl-4-ethylpyridine, a basic product obtained from the alk. degradation of strychnine and brucine, by Hantzsch's general method for pyridines. Cooled piperidine (16 g.) was added to a chilled mixt. of $AcCH_2CO_2Et$ (115 g.) and EtCHO (25 g.) and, after 2 hrs. in the freezing mixt., the reaction mixt. was kept overnight at 0°. NH_3 (8 g.) was passed into the mixt. and, after the addn. of 5 cc. of NH_4OH (d. 0.880), the reaction mixt. was heated at 100° for 4 hrs. The cooled product was decompd. with H_2O and recrystn. from alc. gave 115 g. (89%) of pale yellow prisms of di-Et 2,6-dimethyl-4-ethyl-1,4-dihydropyridine-3,5-dicarboxylate (I), $C_{18}H_{29}NO_4$, m. 112°, oxidized in ether with nitrous fumes or in alc. with I to di-Et 2,6-dimethyl-4-ethylpyridine-3,5-dicarboxylate (II), $b_{0.8}$ 135–40°; picrate, m. 116°. The crude K salt, obtained by alc. KOH hydrolysis of II, was mixed with 2 parts of soda lime and distd., yielding 90% of 2,6-dimethyl-4-ethylpyridine (III), b. 184–6°; picrate, m. 121°; HCl salt, m. 97°. Condensation of 7 g. III with 6.5 g. BzH in the presence of $ZnCl_2$ by heating in a sealed tube for 4 hrs. at 140° and 180–5° for 4 hrs. more gave a viscous red liquid which was made alk. with NaOH and extd. with ether. The residue from the evapn. of the washed and dried ext. was steam-distd., taken up in petr. ether and treated with dry HCl, yielding 0.4 g. of 2,6-distyryl-4-ethylpyridine-HCl, $C_{23}H_{21}N.HCl$, m. 271–2° (decompn.); chloroplatinate, m. 263°(decompn.); chloroaurate, m. 200°. The filtrate was treated with picric acid and gave a *monostyryl deriv. picrate*, $C_{18}H_{17}N.C_6H_3N_3O_7$, m. 232–3°, which was not further characterized. The mother liquor from the picrate was evapd. to dryness, triturated with NaOH, dild. and extd. with ether. The dry ether ext. was treated with dry HCl and the insol. HCl salt was recrystd. from alc. ether, producing *α-phenyl-β-6-(2-methyl-4-ethylpyridyl)ethanol-HCl*, $C_{15}H_{15}NO.HCl$, m. 175°; *chloroplatinate*, m. 125°; *picrate*, prisms from MeOH. **II. New synthesis of 2-methyl-4-ethylpyridine.** Rafat Husain Siddiqui and Abdul Quddus Khan. *Ibid.* 415–18.—A mixt. of 12 g. of 2,6-dimethyl-4-ethylpyridine (I), 9.5 g. BzH, and 12 g. Ac_2O was refluxed for 14 hrs., acidified with dil. HCl and steam-distd. A cryst. distyryl deriv. HCl salt (II) sepd. in a pasty residue. The cooled aq. mother liquor was filtered, made alk. with NaOH and shaken out with petr. ether. Evapn. of the ext. gave a viscous oily base from which I was removed by distn., leaving *2-styryl-4-ethyl-6-methylpyridine* (III), $C_{16}H_{17}N$, b_2 205°; *HCl salt*, m. 208°; *HI salt*, m. 203°; *chloroplatinate*, m. 243°; *chloroaurate*, m. 145°; and *picrate*, m. 233°. II gave the free base, *2,6-distyryl-4-ethylpyridine* (IV), $C_{23}H_{21}N$, m. 85°; II, m. 271–2°; *picrate*, m. 255°. IV could not be condensed with BzH by heating with Ac_2O for 15 hrs. Oxidation of 10 g. III in 200 cc. acetone with 17 g. $KMnO_4$ gave oily 4-ethyl-6-methylpyridine-2-α-carboxylic acid, decarboxylated by heating with Cu powder to 2-methyl-4-ethylpyridine; *picrate* (V), m. 142°. A mixt. of V and the picrate of the base $C_8H_{11}N$ (VI), obtained by alk. degradation of strychnine and brucine, melts at 125°, proving the non-identity of VI and 2-methyl-4-ethylpyridine.

C. R. Addinall

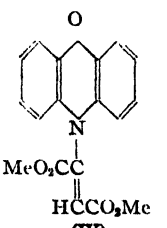
Derivatives of pyridine and quinoline. XLIV. The reactivity of the bromine atoms in brominated pyridines; the formation of 1-methyl-6-bromo-2-pyridone from 1-methyl-2,6-dibromopyridinium salts. J. P. Wibaut, B. W. Speekman and H. M. van Wagtendonk. *Rec. trav. chim.* **58**, 1100–4(1939)(in English); cf. *C. A.* **34**, 1018[3].—2,6-Dibromopyridine (I) (8 g.) and 8.4 g. Me_2SO_4, heated 2 hrs. on the water bath and the product extd. with H_2O, give an aq. soln. of 1-methyl-2,6-dibromopyridinium methylsulfate (II); with alkali at room temp. this yields *1-methyl-6-bromo-2-pyridone* (III), m. 105–5.5° (35% on the I used). In this reaction it is assumed that the base is isomerized to the hypothetical pyridanol base which splits off HBr. III and PBr_5 give I, thus establishing its structure. II and KI give *1-methyl-2,6-dibromopyridinium iodide*, dark yellow, m. 170° (decompn.); this also results in low yield by heating I with MeI for 6 hrs. at 100°. The action of aq. alkali gives III and a compd. m. 177–8°, the nature of which is unknown. **XLV. The reactivity of the bromine atoms in brominated pyridines. The formation of 2,6-diamino-4-bromopyridine by the action of ammonia on 2,4,6-tribromopyridine.** J. P. Wibaut, A. F. Bickel and L. Brandon. *Ibid.* 1124–6.—2,4,6-Tribromopyridine (4 g.) and 20 cc. NH_4OH (d. 0.9), heated 11 hrs. at 200°, give 1.9 g. (crude) of *2,6-diamino-4-bromopyridine* (I), m. 126°; I also results in low yields by heating with liquid NH_3 at about 130° for 24 hrs. (pressure, 90 atm.); there also results a small quantity of an *aminodibromopyridine*, m. 155–8°. Catalytic reduction (Ni) of I gives 2,6-diaminopyridine.

C. J. West



Organolithium compounds of pyridine and quinoline. Henry Gilman and S. M. Spatz. *J. Am. Chem. Soc.* **62**, 446(1940).—Reaction of 3-bromoquinoline and a slight excess of BuLi in Et_2O at −35° for 15 min., followed by carbonation, give 52% of 3-quinolinecarboxylic acid; similarly, 3-bromopyridine gives 70% of nicotinic acid. Details will be reported later. C. J. West

Sulfanilamide derivatives. V. Constitution and properties of 2-sulfanilamidopyridine. M. L. Crossley, E. H. Northey and Martin E. Hultquist. *J. Am. Chem. Soc.* 62, 372-4(1940); cf. *C. A.* **34**, 3928.—2-Aminopyridine (I) and *p*-AcNHC$_6$H$_4$SO$_2$Cl in dioxane, warmed at 95° for 15 min., give 92.8% of 2-(*N*^{4}-acetylsulfanilamido)-pyridine, m. 225.2-8.1°, 229° (Dennis block); on heating at 230° for 5 min., it m. 190-227.5°, indicating thermal decompn. The free base (II) m. 190.4-1.5°, 192° (Dennis block); soly. in H_2O (g./100 cc.): 1.05 g. at 100°, 0.11 g. at 40°, 0.05 g. at 20°. II is sol. in concd. HCl but the salt is highly dissocd. (potentiometric titration); the HCl soln. may be titrated quant. by diazotization with $NaNO_2$, the reaction involving only the NH_2 group of the sulfanilamide part of the mol. No hydrolysis of II occurs on boiling with 50% NaOH or weaker strength; with boiling 36% HCl a practically quant. yield of I and *p*-$H_2NC_6H_4SO_3H$ results. II forms a mono-Na salt which hydrolyzes in H_2O to give a pH of 10-11. These results justify the name of 2-sulfanilamidopyridine for II. C. J. West



Acridine derivatives as antimalarials. IV. S. J. Das-Gupta. *J. Indian Chem. Soc.* **16**, 364-8(1939).—The sulfamyl(dialkylaminoalkylamino)acridine derivs. (*C. A.* **33**, 5852[5]) have been found to possess bacteriostatic action against certain hemolytic streptococci and to be toxic to paramecium. Since the range of activity of the sulfanilamides may be widened by substitution of the NH_2 grouping certain (sulfamylphenylsulfamyl)-5-dialkylaminoalkylaminoacridines and 5-acridylsulfanilylsulfanilamides have been prepd. Unlike other acridine derivs. they are comparatively tasteless, but possess, particularly in neutral solns., the characteristic fluorescence of the 5-aminoacridines. Trituration of a mixt. of 1 mol. of 2,5-Cl(ClO$_2$S)-C$_6$H$_3$CO$_2$H (I) and 2 mols. of *p*-$H_2NC_6H_4SO_2NH_2$ with a little H_2O for 2 hrs., addn. of Na_2SO_3, standing overnight, acidification with dil. HCl and crystn. of the product from dil. alc. gave colorless needles of *2-chloro-5-(p-sulfamylphenylsulfamyl)benzoic acid* (II), $C_{13}H_{11}ClN_2O_6S_2$, m. 240°. A mixt. of 15.6 g. II, 5 g. of *p*-MeOC$_6$H$_4$NH$_2$ and 5.5 g. anhyd. K_2CO_3 was refluxed in AmOH in the presence of Cu powder for 4 hrs. The reaction product was dild. and steam-distd. The filtered residue was acidified and the product was recrystd. from dil. alc., yielding colorless needles of *4-(p-sulfamylphenylsulfamyl)-4'-methoxydiphenylamine-2-carboxylic acid* (III), $C_{20}H_{19}N_3O_7S_2$, m. 246°. III was heated with excess $POCl_3$ on the steam bath for 2 hrs., the excess $POCl_3$ was removed *in vacuo* and the residue was decompd. with very dil. NH_4OH. Crystn. of the solid product from dil. acetone gave needles of *3-(p-sulfamylphenylsulfamyl)-7-methoxy-5-chloroacridine* (IV), $C_{20}H_{16}ClN_3O_5S_2$, m. 212-15°. A mixt. of 3 g. IV in 10 g. PhOH at 100° and 2 g. of $Et_2NCH_2CH_2CH_2CHMeNH_2$ (V) was kept at 100° for 2 hrs. and poured into 150 cc. of cold 5% NaOH. After extn. with ether and neutralization with HCl the semisolid mass was taken up in AcOH, filtered, extd. with ether and made alk. with cold NH_4OH. Crystn. of the ppt. from an acetone-petr. ether mixt. produces yellow crystals of *3-(p-sulfamylphenylsulfamyl)-7-methoxy-5-(4-diethylamino-1-methylbutylamino)acridine*, $C_{28}H_{37}N_6O_5S_2$, m. 254-6°, showing emerald-green fluorescence in alc. Similar condensation of III with $Et_2NCH_2CH_2CH_2NH_2$ (VI) gave the corresponding *4-diethylaminobutyl compd.*, $C_{28}H_{35}N_5O_5S_2$, m. 220-2°. Condensation of I with $H_2NC_6H_4SO_2NEt_2$ gave colorless needles of *2-chloro-5-(p-diethylsulfamylphenylsulfamyl)benzoic acid*, $C_{17}H_{19}ClN_2O_6S_2$, m. 194-5°, condensed with *p*-MeOC$_6$H$_4$NH$_2$ to the *diphenylamine acid*, $C_{24}H_{27}N_3O_7S_2$. Acridination with $POCl_3$ yielded the corresponding *chloroacridine* (VII), $C_{24}H_{24}ClN_3O_5S_2$, m. 187-9°, which was condensed in PhOH with V to give *3-(p-diethylsulfamylphenylsulfamyl)-7-methoxy-5-(4-diethylamino-1-methylbutylamino)acridine*, $C_{38}H_{48}N_6O_5S_2$, m. about 160°. Similar condensations of VII and VI and $Et_2NCH_2CH_2CH_2NH_2$ gave the corresponding *4-diethylaminobutyl-* and *3-diethylaminopropyl compds.*, $C_{32}H_{42}N_5O_5S_2$, m. about 130°, and $C_{31}H_{41}N_6O_5S_2$, m. about 200°. Trituration of $H_2NC_6H_4SO_2NEt_2$ (1 mol.) and *p*-AcNHC$_6$H$_4$SO$_2$Cl (1 mol.) with H_2O, addn. of Na_2CO_3, standing overnight and recrystn. from hot benzene gave an *Ac deriv.*, m. 238°, which was hydrolyzed by refluxing with excess 5% alc. HCl for 30 min. The ppt. formed on neutralization with cold NH_4OH was recrystd. from dil. alc. and gave colorless crystals of *4-(p-aminobenzenesulfonylamino)benzenesulfondiethylamide* (VIII), $C_{16}H_{21}N_3O_4S_2$, m. 176°. A mixt. of 2-chloro-7-methoxy-5-chloroacridine (1 mol.) and VIII (1 mol.) was heated in PhOH at 140° for 3 hrs. The reaction product was poured into cold NaOH. The solid product was taken up in AcOH and filtered. The residue was crystd. from acetone-petr. ether mixt. and gave bright yellow crystals of a *5-acridylsulfanilylsulfanilamide*, $C_{30}H_{29}ClN_4O_5S_2$, m. 160-1°. The corresponding *7-Me deriv.*, $C_{30}H_{29}ClN_4O_4S_2$, m. 133-4°, was prepd. by condensing VIII with 2-chloro-7-methyl-5-chloroacridine under similar conditions.

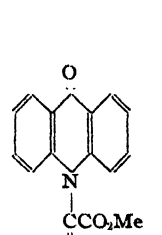
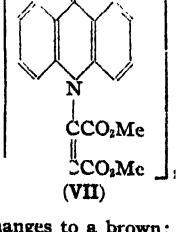
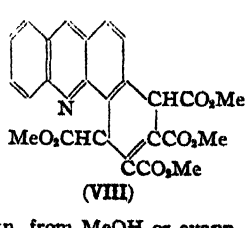
Diene syntheses. XXXIII. Acridine and acetylenedicarboxylic esters. Otto Diels and Wolfgang Ernst Thiele. *Ann.* **543**, 79-94(1939); cf. *C. A.* **32**, 7029[6].—Acridine (I) (17.9 g.) and 12.5 cc. (:CCO$_2$Me)$_2$ (II) in 80 cc. MeOH give in 2 days a blood-red soln. which on cooling gives 26-30 g. of the brick-red *MeOH adduct* (III), m. 104°, and on concn. of the mother liquor 0.3-0.6 g. of a light yellow *isomer*, m. 118°. A mixt. of 35.8 g. I and 48 cc. II in 200 cc. dioxane gives a dark red soln.; evapn. of the solvent gives a dark red oil which, crystd. from 200 cc. MeOH, gives 55-65 g. of red crystals; crystn. from MeCN gives 10-15 g. of a light yellow *adduct* (IV), m. 222-3°, and from the deep red mother liquor 40-50 g. of a ruby-red *adduct* (V), m. 164-5°. With ether as a solvent 66% of the product is IV; the yield of V is very small; there also results some VI. When III or its soln. in MeOH stands in the air for several weeks its color gradually



(III)

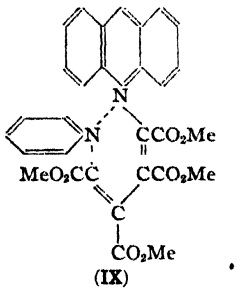


(IV)



(V)

(VI)



(VII)

(VIII)

changes to a brown; recrystn. from MeOH or evapn. of the brown soln. gives the bright orange *compd.* (VI), m. 142-3° (quick heating); on slow heating it gives a citron-yellow compd., m. 163°, which yields the lower-melting

compd. on crystn. from MeOH. When 17.9 g. of I and 12 cc. II in 120 cc. MeOH and 15 cc. perhydrol are allowed to stand several days, there results a small quantity of IV and a nearly quant. yield of VI. Crystn. of IV from a little hot C_5H_5N gives only VI. Heating 30 g. III in 200 cc. MeOH with 20 cc. perhydrol for 1 hr. on the water bath gives 1.6 g. of a dark red adduct (VII), m. 265–6°, and 90–5% of VI. Soln. of 5 g. V in 9 cc. concd. H_2SO_4 gives a brown soln. with a green-yellow fluorescence; on pouring into 200 cc. H_2O there ppts. a yellow oil; crystn. from MeCN gives the *adduct* (VIII), m. 189–90°. Heating 17.7 g. III in 75 cc. MeOH with 6 g. KOH in 75 cc. H_2O for 2 hrs. on the water bath gives a yellow-orange *compd.*, $C_{16}H_{11}O_3N$, m. 241-2°. I (5.4 g.) and II in 30 cc. EtOH give 5–6 g. of the *EtOH adduct* corresponding to III, m. 71°; in the air it gives VI somewhat more quickly than III; crystn. from MeOH gives III. V with excess HCO_2H gives a yellow soln. with a green fluorescence; crystn. of the red-yellow resin from MeOH gives an orange *compd.*, $C_{25}H_{21}O_8N$, m. 159–60°. Boiling V with $N_2H_4 \cdot H_2O$ in MeCN gives a light orange *compd.*, $C_{21}H_{21}O_4N_3 \cdot 1.5H_2O$, insol. in the usual solvents; C_5H_5N gives the orange *compd.* (IX), m. 123°; boiling with MeOH or EtOH gives V. Heating V with isoquinoline (nearly to boiling) gives an orange *compd.*, $C_{36}H_{31}O_8N_3$, m. 205°. V and *p*-quinone on melting give an orange-brown compd., $C_{31}H_{25}O_{10}N$, m. 232° (decompn.). $(:NCO_2Et)_2$ in PhMe, refluxed 6 hrs. (color change of soln. from red through green and blue to violet) gives the *compd.* $C_{37}H_{41}O_{16}N_3$, m. 203–4°. Heating V with maleic anhydride at 100° gives a blood-red smeary mass which, extd. with MeOH and crystd. from AcOH, gives an orange *compd.*, $C_{29}H_{23}O_{11}N$, m. 259° (decompn.). Heating III with a little concd. HCl gives *N-methylacridinium chloride*, $C_{14}H_{12}NCl.3H_2O$, m. 122° (decompn.). Hydrolysis of 10 g. VI with 4 g. KOH in 50 cc. H_2O and 60 cc. MeOH on the water bath and addn. of 100 cc. dil. HCl gives 9 g. of the *acid*, $C_{17}H_{11}O_5N$, yellow, m. 255° (decompn.); IV gives an isomeric acid, with 1.5 mols. H_2O, m. 225° (decompn.). Reduction of 5 g. VI with Zn and concd. HCl in MeOH gives 3.5-4 g. of the *compd.*, $C_{38}H_{34}O_8N_2$, yellow green with light green fluorescence, m. 260° (decompn.); IV gives the same compd.

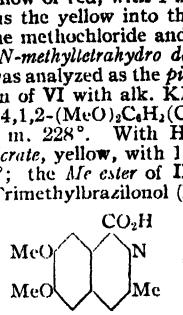
(IX)

C. J. West

3-Methyl-3,4-dihydroisoquinolines and 3-methyl-1,2,3-4-tetrahydroisoquinolines. Walter S. Ide and Johannes S. Buck. *J. Am. Chem. Soc.* 62, 425–8(1940).—Details are given of the prepn. of α-methyl-3,4-dimethoxycinnamic acid (I) by the Claisen method from veratraldehyde (II) and $EtCO_2Et$ with Na, followed by hydrolysis and by the Reformatsky reaction from II, $MeCHBrCO_2Et$ and Zn in C_6H_6, then by refluxing of the C_6H_6 soln. with $POCl_3$ and hydrolysis; fractionated from C_6H_6, I m. 232° (20% yield, probably trans isomer) and 144° (yield of this isomer not given); the 3,4-methylenedioxy analog m. 200°. *α-Methyl-3,4-dimethoxypropionamide*, m. 109°, results from heating the NH_4 salt in a stream of NH_3 for 2 hrs. at 220° or from the acid chloride with NH_4OH contg. NaOH; the *3,4-methylenedioxy analog* m. 122°. With NaOCl there results 53% of $3,4\text{-}(MeO)_2C_6H_3CH_2CHMeNH_2$, b_9 154°, n_D 1.5347, d_4^{25} 1.0624; $3,4\text{-}CH_2O_2C_6H_3CH_2CHMeNH_2$, b_{11} 143–5°, n_D 1.5394, d_4^{25} 1.1277, 40% yield. The isoquinolines were prepd. by cyclizing the formyl derivs. (*C. A.* 32, 8424[3]). *3-Methyl-6,7-dimethoxy-3,4-dihydroisoquinoline-HCl* (III), yellow, m. 189° (m. ps. cor.); *6,7-methylenedioxy analog* (IV), light ivory or tan, m. 198°; reduction of III with Zn in hot dil. H_2SO_4 gives the *1,2,3,4-tetrahydro deriv.*, m. 245°; the 1,2,3,4-tetrahydro deriv. from IV m. 238°; demethylation of III with HCl at 170° gives *3-methyl-6,7-dihydroxy-3,4-dihydroisoquinoline-HCl*, yellow, m. 297°; *1,2,3,4-tetrahydro deriv.*, m. 270°. The free base from III with MeI in cold C_6H_6 yields *2,3-dimethyl-6,7-dimethoxy-3,4-dihydroisoquinolinium iodide* (V), yellow, m. 156°; AgCl in cold aq. soln. gives the *chloride*, yellow, m. 125–8°; *6,7-methylenedioxy analog* of V, brown-yellow, m. 213°; *chloride*, light ivory, m. 212°; the *6,7-di-HO analog* of V, yellow, m. 199°; reduction of V gives *2,3-dimethyl-6,7-dimethoxy-1,2,3,4-tetrahydroisoquinoline-HCl* (VI), m. 232°; the free *base* (VII) m. 100°; the *6,7-methylenedioxy analog* of VI m. 228–9°; the free base m. 88°; *2,3-dimethyl-6,7-dihydroxy-1,2,3,4-tetrahydroisoquinoline-HCl* m. 266°. VII and MeI in cold C_6H_6 give *2,2,3-trimethyl-6,7-dimethoxy-1,2,3,4-tetrahydroisoquinolinium iodide*, m. 232°; the *chloride* m. 239°; the 6,7-methylenedioxy analogs m. 242 and 248–50°, resp. *2,2,3-Trimethyl-6,7-dihydroxy-1,2,3,4-tetrahydroisoquinolinium chloride* m. 258°. The yields are stated to be good at each stage.

C. J. West

Molecular associations of barbiturates and local anesthetics. G. Lusignani. *Ann. chim. farm.* (Suppl. to *Farm. ital.*) Dec., 1939, 64–9.—When cautiously fused together 1 mol. ethylphenylbarbituric acid (I) unites with 2 mols. Et *p*-aminobenzoate (II) to form a stable *compd.*, $C_{26}H_{26}N_4O_7$. In like manner 1 mol. diethylbarbituric acid (III) and 2 mols. II form a *compd.*, $C_{22}H_{26}N_4O_7$, m. 119°. I and 2 mols. procaine, form a *compd.*, $C_{38}H_{52}N_6O_7$, m. 155°, and III and 2 mols. procaine form a hygroscopic *compd.* m. 140°. All 4 of the new compds. are sol. in hot water, cold aq. alkalies, and in most org. solvents but are insol. in C_6H_6 and petr. ether.



L. E. Gilson

Pyrimidines. CLXIV. Synthesis from uracil of pyrimidines related structurally to thiamine. Doris Riehl and Treat B. Johnson. *Rec. trav. chim.* 59, 87–95(1940) (in English); cf. *C. A.* 33, 8572[8].—This is a part of a study to det. whether pyrimidine constructions related to the reduced pyrimidine structure of thiamine (vitamin B_1) can be prepd. from compds. of the uracil (I) type by any synthetic process of practical utility. I (1.5 g.) and 2 g. $BzNHCH_2OG$ in 10 cc. concd. H_2SO_4, allowed to stand at room temp. 5–48 hrs. and dild. with 100 cc. H_2O, give methylenedibenzamide as a ppt. and a H_2SO_4 filtrate which, after removal of the acid with $BaSO_4$ and evapn. to dryness, gives after crystn. from H_2O and EtOH *benzoylthyminylamine*, $CO.NH.CO.NH.CH:CCH_3NHBz$, m. 209–11° (decompn.); this is hydrolyzed by warm HCl to I, NH_3 and BzOH; the compd. was never obtained in sufficient quantity for further synthetic work. I and $C_6H_4(CO)_2NCH_2OH$ in concd. H_2SO_4, allowed to stand 3–6 days and dild. with 10 times its vol. of H_2O, give a gummy ppt. (II) and after a few hrs. a cryst. ppt. (III); II and III are formed in about equal proportions; the crude combined yields after 2, 3, 4 and 6 days were 72, 75, 82 and 87%. II is sol. in dil. NaOH and is not pptd. by HCl; it is hydrolyzed only after prolonged digestion with HCl; derivs. could not be prepd. with Br or $POCl_3$. Extn. of III with C_6H_6 gives as a residue *5-phthalimidomethyluracil* or *phthaloylthyminylamine* (IV), $CO.NH.CO.NH.CH:C\text{-}CH_2N(CO_2)C_6H_4$, m. 254–5°; hydrolysis with HCl gives I, NH_3 and $C_6H_4(CO_2H)_2$. IV and Br in H_2O at room temp. give *4-hydroxy-5-bromo-5-phthalimidomethyluracil*, decomps. 278–82°; refluxing with concd. HCl for 1 hr. gives I and $C_6H_4(CO_2H)_2$. IV and $POCl_3$, refluxed for 1 hr. at 130–5° and 1.5 hrs. at 140–5°, give a product which finally yielded a compd. believed to be 2-chloro-6-hydroxy- or 2-hydroxy-6-chloro-5-phthalimidomethylpyrimidine, m. 150–5°, which may be formed by partial hydrolysis of the expected 2,6-di-Cl deriv. The IV apparently undergoes partial hydrolysis, giving I and $C_6H_4(CO)_2NCH_2Cl$, whereas

a part reacts normally to give the 2,6-di-Cl deriv. IV and $N_2H_4.H_2O$ do not give 5-phthalimidomethyluracil. C. J. West

Reactions of bis-β-chloroethyl ether with ethylenediamine. M. E. Hultquist and E. H. Northey. *J. Am. Chem. Soc.* **62**, 447–8(1940).—$C_2H_4(NH_2)_2$ (1.875 kg. of 57.5%, 18 moles anhydr.), treated with 863 g. (6 moles) of $(ClCH_2CH_2)_2O$ during 1 hr. and after 30 min. with 505 g. flake NaOH, gives 370 g. (47.5%) of 4-(β-aminoethyl)-morpholine (I). The residues give 50 g. b_{68} 123° to b_{30} 164°, 69 g. b_{30} 164–6° (mainly ethylenedi(4-morpholine), m. 70–3° (*di-HCl salt*, decomps. and sublimes above 250°)), 8.5 g. b_{30} 166–200°, 7.3 g. b_{30} 200 3° (mainly bis-[2-(*N*-β-aminoethylamino)ethyl] ether, light yellow oil, whose *tetra-HCl salt* m. 185–7°), and 5.5 g. b_{20} 203° to b_4 220°. With 6 moles of $C_2H_4(NH_2)_2$ to 1 of ether the yield of I is 58% (based on the ether). C. J. W.

Alkaloid-like compounds from brazilin and hematoxylin. P. Pfeiffer, J. Breitbach and W. Scholl. *J. prakt. Chem.* **154**, 157–208(1940).—Through a series of simple reactions brazilin and hematoxylin may be converted into alkaloid-like compds. which are closely related to papaverine and laudanosine. Hematoxylin is methylated and oxidized to tetramethylhematoxylone, which is reduced by Mg and AcOH to tetramethylhematoxylonol (I) (*C. A.* **32**, 4597[7]); oxime (II), $C_{20}H_{22}O_7N$, m. 223° (decompn.); the halochromy of II is wine-red, with a blue-lilac filtrate; HCl in MeOH gives I. Heating 20 g. I and 8 g. NH_2OH-HCl with 10 g. KOH in 100 cc. EtOH for 4 hrs. on the water bath, pouring into 400 cc. H_2O, neutralizing with AcOH and crystg. the crude product (20 g.) from EtOH or C_6H_6 gives *anhydrotetramethylhematoxylonol oxime* [*1-(2'-hydroxy-3',4'-dimethoxyphenyl)-3-methyl-6,7-dimethoxyisoquinoline oxide*] (III), $C_{20}H_{21}O_6N$, leaflets, m. 220°; III also results on heating II in EtOH with alkali; it also crystallizes as long needles, m. 191 2°, changing after several days to the stable form; the presence of a phenolic HO group is indicated by the soly. of III in cold dil. NaOH and its pptn. by CO_2; 4 of the O atoms are present as MeO groups; the 6th O atom is in the form of a N.O group, as shown by the formation of VI with SO_2 in AcOH. III (1 g.) and 1 g. MeI in 2.5 g. NaOH in 50 cc. H_2O, refluxed 6 hrs., give 0.4 g. of the *methiodide* (IV), $C_{22}H_{26}O_6NI$, yellow, m. 227–8°; IV results in a nearly quant. yield by heating 1 g. I and 5 cc. MeI with 25 cc. NaOH in 50 cc. H_2O and 40 cc. EtOH for 15 hrs. and then passing CO_2 through the boiling soln. for 3 hrs. In this reaction the phenolic HO group is methylated and the N.O group is transformed into NMeI. Heating III and Me_2SO_4 in C_6H_6, removing the C_6H_6, dissolving the residue in H_2O and adding satd. KI in H_2O, give the *methiodide* (V) of III, $C_{21}H_{24}O_6NI$, which seps. from a dil. MeOH soln. in the dark as light yellow crystals, m. 206–8°, sensitive to light; in this reaction the N.O group is changed to NO-MeI. The *picrate* of III, grayish yellow, m. 216–17° (decompn.). Addn. of 5 g. Zn in portions to 10 g. III in 50 cc. hot AcOH and allowing the mixt. to stand 12 hrs. at room temp. give the *desoxoanhydro compd.* [*1-(2'-hydroxy-3',4'-dimethoxyphenyl)-3-methyl-6,7-dimethoxyisoquinoline*] (VI), m. 174°; H_2SO_4 causes no halochromy; in this reaction the O of the N.O group is split off; $ClCH_2$-CH_2OH in MeOH gives a decided brown color in 30 min.; without the MeOH the color appears in 9 hrs. (test for an epichlorohydrin). VI in hot HCl or dry HCl in C_6H_6 gives the *HCl salt*, decomps. 230–5°; *picrate*, yellow, m. 210°. VI and Me_2SO_4 in C_6H_6 give the *methosulfate*, m. 168–70°; KI gives the *methiodide* (VII), pale yellow, m. 230–1°, which also results from VI and MeI in $CHCl_3$. Warming 1 g. VI and 1 g. AcONa in 15 cc. Ac_2O for 1 hr. on the water bath gives the *acetate*, m. 174° (*hydrate*, m. 86–8°; *picrate*, light yellow, m. 202–3°; *methiodide*, with 1 mol. H_2O, pale yellow, m. 118°). VI and Me_2SO_4 in 5% NaOH give the *Me ether* [*1-(2',3',4'-trimethoxyphenyl)-3-methyl-6,7-dimethoxyisoquinoline*] (VIII), m. 129–30°; *picrate*, golden yellow, m. 185–6°; the *methiodide*, yellow, m. 227 8°, results from VI and MeI in MeOH-NaOH, from MeI in $CHCl_3$, followed by MeI in NaOH, or from VIII and MeI in $CHCl_3$. Reduction of III or VI with Na in boiling EtOH gives *1-(2-hydroxy-3',4'-dimethoxyphenyl)-3-methyl-6,7-dimethoxytetrahydroisoquinoline*, $C_{20}H_{25}O_5N$, m. 181–4°; *picrate*, yellow or red, with 1 mol. H_2O, m. 175–8°; light transforms the yellow into the red form. VII, transformed into the methochloride and reduced with Zn in HCl, gives the *N-methyltetrahydro deriv.*, which could not be crystd. but was analyzed as the *picrate*, light yellow, m. 190°. Oxidation of VI with alk. $KMnO_4$ gives metahemipinic acid, 3,4,1,2-$(MeO)_2C_6H_2(CO_2H)_2$, identified as the ethylimide, m. 228°. With HNO_3 VI gives an *acid* (IX), whose *picrate*, yellow, with 1 mol. H_2O or MeOH, decomps. 240°; the *Me ester* of IX forms a *picrate*, yellow, m. 212°. Trimethylbrazilonol (X) oxime, warmed

(IX)

with KOH in C_5H_5N or EtOH for 0.5 hr., or X, NH_2OH.HCl, KOH and EtOH refluxed 4 hrs., give the *anhydro compd.* [*1-(2'-hydroxy-4'-methoxyphenyl)-3-methyl-6,7-dimethoxyisoquinoline oxide*] (XI), m. 243°; *HCl salt*, m. 131° (decompn.); *Bz compd.*, m. 176°; the *Me ether* could not be crystd.; its *picrate* m. 180 5°; *HCl salt*, decomps. 115°. Reduction of XI with Zn or SO_2 in hot AcOH gives the *desoxoanhydro compd.*, *1-(2'-hydroxy-4'-methoxyphenyl)-3-methyl-6,7-dimethoxyisoquinoline* (XII), m. 188 9°; *picrate*, orange-yellow, m. 224 5°; *methiodide*, with 1.33 mols. H_2O, m. 207 8°. The *Me ether* (XIIA) of XII m. 110°; it was purified through the *picrate*, m. 212 15°; *methosulfate*, m. 170°; *methiodide*, with 0.5 mol. H_2O, yellow, m. 170°. Dimethyl-β-resorcylic acid with PCl_5 or $SOCl_2$ gives the *chloride* (XIII), m. 54 6°; *amide*, m. 132°; *anilide*, m. 141°. *α-(3,4-Dimethoxyphenyl)-β-aminopropanol* (XIV), m. 128 9°, results from hydrolysis of the Ac deriv. (Bruckner, *C. A.* **29**, 5825[6]). Condensation of XIII and XIV in C_6H_6 gives 96% of the *acylamide*, 3,4-$(MeO)_2C_6H_3CH(OH)CHMe$-$NHCOC_6H_3(OMe)_2$-2,4, pale yellow resin; ring closure with $POCl_3$ in PhMe gives *1-(2',4'-dimethoxyphenyl)-3-methyl-7,8-dimethoxyisoquinoline*, m. 144 5° (crude yield, 76.8%); *picrate*, deep yellow, m. 232 5°; *methosulfate*, m. 239°; *methiodide*, yellow, m. 217–19° (decompn.); the *tetrahydro deriv.* yields a *picrate*, deep golden yellow, m. 203 5°. The isomeric XIIA could not be detected by fractional crystn. of the crude base or its picrate or by chromatographic fractionation from C_6H_6 on Al_2O_3. 2,4-$HO(MeO)C_6H_3CO_2H$ with $PhNMe_2$ and $ClCO_2Et$ in C_6H_6-Et_2O gives the *2-carbethoxy deriv.*, m. 111° (decompn.); the *chloride* (XV) is a yellow oil; *anilide*, m. 215°. Condensation of XV and XIV in C_5H_5N-C_6H_6 gives the *amide*, 3,4-$(MeO)_2C_6H_3CH(OH)CHMeNHCOC_6H_3(OCO_2Et)$-OMe-2,4, a yellow resin; ring closure yields *1-(2'-hydroxy-4'-methoxyphenyl)-3-methyl-7,8-dimethoxyisoquinoline*, whose yellow picrate decomps. 272–5°. XIV and 2,3,4-$(MeO)_3C_6H_2COCl$ give the *amide*, 3,4-$(MeO)_2C_6H_3CH$-$(OH)CHMeNHCOC_6H_2(OMe)_3$-2,3,4, m. 127 8°; ring closure gives 94% of *1-(2',3',4'-trimethoxyphenyl)-3-methyl-7,8-dimethoxyisoquinoline*, m. 110 12°; *picrate*, yellow, m. 183–4°; *methosulfate*, m. 225–7°; *methiodide*, pale yellow, m. 226 7° (decompn.). Thus, in no case was a synthetic product obtained which was identical with those prepd. from the natural compds. C. J. West

Alkaloids of Rauwolfia serpentina, Benth. Salimuzzaman Siddiqui. *J. Indian Chem. Soc.* **16**, 421–2(1939).—Roots of *R. serpentina* collected in the hot swampy districts of Bihar contain the white cryst. bases ajmaline (I), ajmalinine (II), ajmalicine, and the bright yellow cryst. bases serpentine (III) and serpentinine (*C. A.* **29**, 4016[7]). Roots from the climatically milder Dehra Dun Valley contain very little of the yellow group of bases, which are oxidation products of the white ajmaline series, an observation of therapeutic importance since the ajmaline group of alkaloids has valuable hypnotic and sedative properties. The Dehra Dun drug contained no I, and only traces of II and III. Isoajmaline (IV), m. 264–6°, and neoajmaline, m. 205–7°, which can be converted into IV on heating at

270° or with alc. KOH, were isolated in 0.1 and 1% yields from the root-bark, and 0.01 and 0.1% from the whole roots. Another new alkaloid of this group, m. 220°, and a white cryst. amphoteric alkaloid, m. 234°, have also been isolated in 0.02 and 0.1% yields, resp., from the root-bark and whole roots. C. R. Addinall

Erythrina alkaloids. VII. Isolation and characterization of the new alkaloids, erythraline and erythratine. Karl Folkers and Frank Koniuszy. *J. Am. Chem. Soc.* **62**, 436–41(1940); cf. *C. A.* **34**, 4367.—Seeds of *Erythrina fusea* Lour. (980 g.) were extd. with 1500 ml. petr. ether for 6 hrs., giving 7.8% of a yellow fat fraction; the extn. was continued for 36 hrs. with 2 1500-ml. portions of MeOH, giving 15.8% of gum-like material; soln. of the 150 g. in 700 ml. H_2O, addn. of 14 ml. concd. HCl, extn. with petr. ether and then with $CHCl_3$, neutralization with $NaHCO_3$ and extn. with 10 100-ml. portions of $CHCl_3$, gave 0.19% crude *erythraline* (I). Hypaphorine (IA) may be isolated by treating the alk. aq. soln. with HCl, etc., as described in *C. A.* **33**, 5404[5]. Recrystn. and sublimation of I gives 0.068% pure I, $C_{18}H_{19}NO_3$, m. 106–7°, $[\alpha]_D^{25}$ 211.8° (EtOH, *c* 0.944); *HI salt* (II), yellow, m. 252–3° (decompn.), $[\alpha]_D^{25}$ 177° (H_2O, *c* 0.322); *HBr salt*, m. 243°, $[\alpha]_D^{25}$ 216.6° (H_2O, *c* 0.5). *E. glauca* Willd., treated as above, yields 9.4% of fatty materials, 16.6% of MeOH ext. and 0.15% of crude $CHCl_3$ ext. from the alk. aq. soln. The crude bases were transformed into the HI salts and crystd. from 95% EtOH; erythramine (III) HI was isolated in 0.003% yield (based on seed powder); the yield of II was 0.03%. The 3rd fraction, recrystd. from H_2O, was *erythratine* (IV) *III*, m. 242 2.5°, $[\alpha]_D^{25}$ 113.3°. IV can also be isolated by crystg. the crude base mixt. from 95% EtOH; the yield of the *hemihydrate* (V) is 0.018%. V, $C_{18}H_{21}NO_4.0.5H_2O$, m. 170–70.5°, $[\alpha]_D^{25}$ 145.5° (EtOH, *c* 0.371); V also results from the HI salt of IV and $NaHCO_3$. V does not lose its H_2O of crystn. at 140° and 0.01 mm. in 4 hrs. The *HBr salt* of IV m. 241°, $[\alpha]_D^{25}$ 158.7° (H_2O, *c* 0.258). I was also isolated from the seeds of *E. folkersii* Kruk. and Mold., *E. variegata* L. var. *orientalis* (L.) Merr., *E. velutina* Willd., and *E. macrophylla* D. C. IA was isolated from all of the above mentioned species and all for the 1st time except from *E. variegate*. I and IA undoubtedly exist also in *E. velutina* forma *aurantiaca* (Ridl.) Kruk. and *E. grisebachii* Urb. I and III were of comparable activity (7–8 mg./kg.) in causing curare-like paralysis in frogs whereas IV had 0.1 of this activity. C. J. West

The Senecio alkaloids. I. The isolation of isatidine from Senecio retrorsus and Senecio isatideus. H. L. de Waal. *Onderstepoort J. Vet. Sci. Animal Ind.* **12**, 155–63(1939).—*Isatidine* (I) was isolated, for the first time, from *S. retrorsus* D. C. in quantity of approx. 0.3 g. per kg. of the dry plant. The yield of I from *S. isatideus* D. C. was approx. 50 g. per kg. The 2 products had identical properties. *S. retrorus* contained as its main alkaloid *retrorsine*, which was also present in very small quantity in *S. isatideus*. I *picrate*, fine yellowish needles, sol. hot water, hot acetone, hot alc., hot EtOAc. *Isatinecic acid*, (II), $C_{10}H_{16}O_6$, a dicarboxylic acid contg. 1 double bond; obtained by boiling a *N* alc. KOH soln. of I, hydrolyzing the dry residue with HCl, extg. the dry residue from the HCl treatment with hot EtOAc and pptg. the II from the hot, water-free ext. by addn. of petr. ether, prismatic needles, m. 178–80°, $[\alpha]_D^{25}$ 56°. Oxidation of I by $KMnO_4$ in Na_2CO_3 soln. yields oxalic acid as 1 of the products. K. D. Jacob

Alkaloids of Lycoris. XIV. Constitution of lycorine. 6. Heisaburo Kondo and Hirotaro Katura. *J. Pharm. Soc. Japan* **59**, 733–42(1939).—Acetylation of dihydrolycorine gave diacetyldihydrolycorine (I), $C_{16}H_{17}O_4NAc_2$, m. 175°. I in anhyd. benzene when heated on the water bath with BrCN for 1 hr. gave diacetyldihydrolycorine bromocyanide (II), m. 176, which depressed the m. p. of I. II failed to absorb H when reduced catalytically. II gave the following compds.: dihydronorlycorine anhydride (III), $C_{16}H_{19}O_4N.H_2O$, m. 204°; acetyldihydronorlycorine anhydride, m. 167–8°; methyldihydronorlycorine anhydride-MeI, decomp. 275°; Ac deriv., $C_{16}H_{17}O_4N$-MeAc, m. 263°, and dihydrocyanolycorine anhydride (IV), $C_{16}H_{18}NCN$, m. 217°, which gave III when boiled with 30% H_2SO_4 or alc. KOH; Ac deriv., $C_{16}H_{17}O_4N$-(CN)Ac, m. 236°. Oxidation of IV with CrO_3 gave oxodihydronorlycorine anhydride (V), $C_{16}H_{15}O_5N$, decomp. 341°; oxime, decomp. 293–5°. Methylation of V with Me_2SO_4 gave a *N*-Me deriv., $C_{16}H_{14}O_5NMe$, m. 258°; oxime, decomp. 266–8°. Cf. *C. A.* **32**, 7918[1]. F. I. Nakamura

Complete conversion of *l*-ecgonine methyl ester into *l*-cocaine. A. W. K. de Jong. *Rec. trav. chim.* **59**, 27–30(1940)(in English).—A complete conversion is obtained in 10 hrs. by boiling an anhyd. C_6H_6 soln. of *l*-ecgonine Me ester with BzCl in the presence of dry Na_2CO_3, CaO or a mixt. of CaO and $Ca(OH)_2$. In $CHCl_3$ about 20 hrs. are necessary and in Et_2O about 40 hrs., when a mixt. of CaO and $Ca(OH)_2$ is used. C. J. West

Strychnine and brucine. I. Alkaline degradation of strychnine. Rafat Husain Siddiqui. *J. Indian Chem. Soc.* **16**, 396–8(1939).—An intimate mixt. of 1 part of strychnine, 3 parts KOH and 1 part H_2O was distd. from a Cu flask over a free flame and the distillate was extd. with ether. The ext. was shaken out with 10% HCl and this acid ext. was neutralized with NaOH, extd. with ether and treated with picric acid. The crude picrate was decompd. with NaOH and extd. with ether. The residual oil from the dried ext. was fractionally distd. The lower-boiling fraction gave a *picrate* (I), $C_8H_{11}N.C_6H_3N_3O_7$, m. 141–2°, on recrystn. from alc. I is identical with Clemo's base A picrate, m. 143–4° (*C. A.* **31**, 6941). The mother liquors from the prepn. of the crude picrate gave another *picrate*, m. 195–6°, from MeOH. **II. Alkaline degradation of brucine.** Rafat Husain Siddiqui. *Ibid.* 399–401.—Brucine was distd. with 4 parts of KOH from a Cu flask and the distillate was shaken with ether. The ether ext. was extd. with 10% HCl, neutralized with NaOH and again extd. with ether, yielding 5% of residual brownish yellow oil. Fractional distn. gave 5 fractions which were converted into *picrates;* $C_7H_9N.C_6H_3N_3O_7$ (I), m. 143–4°; (II), m. 104–5°; (III), m. 135–6°; (IV), m. 141–2°; and $C_{11}H_{11-13}N.C_6H_3N_3O_7$ (V), m. 172°. II appears to be a mixt. of I and III whereas III gives no appreciable mixed m. p. depression with IV but has a mixed m. p. 105–12° with I. I is common to strychnine and brucine and is identical with Clemo's base A picrate. The solubilities and general behavior of the fractions suggest that they are pyridine derivs. C. R. Addinall

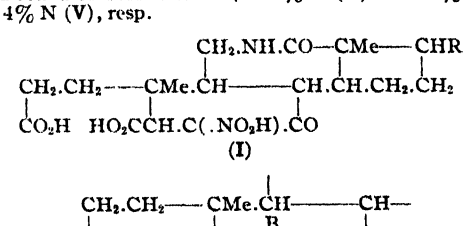
The identity of resin acids. I. Pinabietic acid of Finnish tallöl. Torsten Hasselstrom, John D. McPherson and Sam Hopkins, Jr. *Paper Trade J.* **110**, No. 4, 41–3 (1940).—Pinabietic acid, the terminal resin acid of Finnish tallöl, originally discovered by Aschan, was assumed to be structurally identical with and a stereoisomer of the Levy abietic acid, obtained by vacuum distn. of American rosin and subsequent fractional crystn. of the distillate. Evidence is presented showing that pinabietic acid is not a chem. individual, but a mixt. of at least 3 or 4 resin acids if the presence of *d*-pimaric acid is considered, and that these acids cannot be sepd. by fractional crystn. alone. Pinabietic acid is shown to be a mixt. of Steele's abietic acid, dehydroabietic acid and dihydroabietic acid. The variations in α of the different fractions of pinabietic acid obtained throughout the work are assumed to be due to varying amts. of dihydroabietic and dehydroabietic acids (both *d*-rotatory) which sep. as contaminations together with Steele's abietic acid, which is *l*-rotatory. Resin acids contg. Steele's abietic acid are highly unstable when exposed to O, in contrast to rosins rich in dehydroabietic acid but devoid of Steele's acid. A. Papineau-Couture

Saponins. XV. Constitution of the nitro derivatives of the oleanolic acid series. Satoru Kuwada and Keinosuke Takeda. *J. Pharm. Soc. Japan* **59**, 773–82(in German, 294–8)(1939).—Tri-Me nitroöleanoltrioate (2.5 g.) in 50 cc. glacial AcOH when heated with 5 g. Zn dust on the water bath for 3 hrs. gave 1.3 g. di-Me

ketoöleanollactonedioate (I), $C_{36}H_{42}(CO_2)(CO)(CO_2Me)_2$, m. 229–32°, $[\alpha]_D^{25}$ 98.5° (in $CHCl_3$). I (1 g.) when heated with 50 cc. 10% MeOH-KOH for 5 hrs. on the water bath gave diketolactone monoacid Me ester, $C_{36}H_{41}(CO_2Me)(CO)_2(COO)$, m. 315–18°, $[\alpha]_D^{25}$ −37.7° (in $CHCl_3$); oxime, decomp. 266–6.5°. The above reaction also gave a diketo carboxylic acid, $C_{36}H_{41}(CO_2H)(CO)_2$, m. 259–61°, $[\alpha]_D^{25}$ 73.4° (in $CHCl_3$). Me nitroöleanolketocarboxylate (4 g.) in 100 cc. glacial AcOH when heated on the water bath for 5 hrs. with 20 g. Zn dust gave 2.2 g. diketoöleanolcarboxylic lactone (III), $C_{36}H_{42}(CO_2)(CO)_2$, m. 306–8°, $[\alpha]_D^{25}$ 209.5° (in $CHCl_3$); oxime, decomp. 298–300°. II (1 g.) when treated with MeOH-KOH gave 0.4 g. diketoöleanolcarboxylic acid, $C_{29}H_{42}O_4$, m. 359–61°. Tri-Me nitroöleanintrioate when treated with Zn dust in glacial AcOH as described above gave di-Me ketoöleanin-lactonedioate, $C_{36}H_{40}(CO_2Me)_2(CO)(CO_2)$, m. 237–40°, $[\alpha]_D^{25}$ 97.7° (in $CHCl_3$). F. I. Nakamura

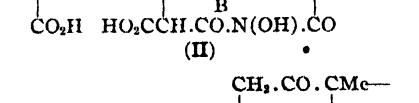
The bitter principle from Andrographis paniculata, Nees. I. A. Moktader and S. S. Guha-Sircar. *J. Indian Chem. Soc.* **16**, 333–8(1939).- Andrographolide (I), $C_{20}H_{30}O_5$ (Gorter, *C. A.* **9**, 442), the bitter principle from the Bengali drug Kalmegh (*A. paniculata*), was re-investigated. Extn. of sun-dried, fully mature leaves with $CHCl_3$ and recrystn. of the crude cryst. product from MeOH and EtOH yielded 0.8–2.5% of cryst. I, m. 220° (decompn.), $[\alpha]_D^{25}$ −123.5°, extremely bitter in very great dilns. I (3.5 g.) in 30 cc. of alc. KOH contg. 7 g. KOH was heated for 1 hr. on the steam bath and the clear yellow soln. was filtered, cooled and acidified with dil. HCl. Recrystn. of the product from hot H_2O gave *isoandrographolic acid* (II), $C_{20}H_{32}O_6$, forming an insol. cryst. *Ba salt* also obtained by boiling 1 g. I with 2.5 cc. of 2% $Ba(OH)_2$. Heating with a slight excess of NH_4OH for 10 min. and acidifying with dil. HCl converted II into an acid, m. 180°, presumably identical with Gortner's andrographolic acid, $C_{20}H_{32}O_6$. I was unchanged on heating for 5–10 min. with Ac_2O and fused AcONa, gave a solid product free from a CH_2O_2 group on treatment with $POCl_3$, and yielded a white amorphous solid, m. 90–5°, on heating with PhNCO, proving the presence of at least 1 OH group. Distn. of I with 33% H_2SO_4 gave HCHO, indicating a CH_2O_2 group in I. Catalytic reduction of 0.3026 g. I in the presence of Pd with 21.1 cc. H gave a *dihydroandrographolide*, $C_{20}H_{32}O_5$, m. 205° (decompn.), whereas reduction with $SnCl_2$ in concd. HCl produced an isomeric *dihydro compd.*, m. 200° (decompn.); mixed m. p. 183–5°. Bromination of I yielded an impure addn. compd.; addn. of HCl formed a *compd.*, $C_{20}H_{31}ClO_5$, m. 55–7°; but the addn. compd. with HBr could not be obtained in the pure state. Estn. with Wijs' soln. indicated the presence of a double bond in I. Gorter's finding that I reacts with anhyd. HCO_2H to form a compd., m. 215°, was not confirmed. C. R. Addinall

Preparation of ferric mesoporphyrin chloride. T. Harrison Davies. *J. Am. Chem. Soc.* **62**, 447(1940).— Ferric protoporphyrin chloride (I) (4 g.) in 450 ml. MeOH and 50 ml. of 0.5 *N* KOH, refluxed about 8 hrs. with Pd charcoal and H, filtered, the filtrate treated with *N* HCl to ppt. the metalloporphyrin, the dried ppt. dissolved in 100 ml. $CHCl_3$ contg. 4 g. quinine and added to 150 ml. glacial AcOH satd. with NaCl, the soln. heated above 90° on a water bath while air is bubbled through to aid in removal of the $CHCl_3$, gives on cooling 2.7–3.2 g. of cryst. ferric mesoporphyrin chloride (II). The absorption spectra of I and II are given. C. J. West



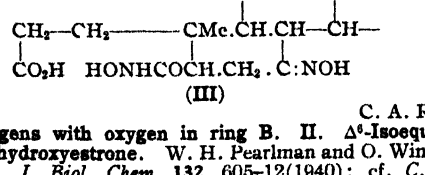
Constitution of the prosthetic group of cytochrome c. Karl Zeile and Hildegard Meyer. *Z. physiol. Chem.* **262**, 178–98(1939).—See *C. A.* **34**, 4402. Milton Levy

Chlorophyll. XCIII. γ-Formylpyrroporphyrin. Hans Fischer and Eberhard Stier. *Ann.* **542**, 224–40(1939); cf. *C. A.* **34**, 7694.—Phylloporphyrin Me ester (I) (500 mg.) in 150 cc. H_2O-free AcOH, treated with 3 g. AcONa in 100 cc. AcOH and then with 1 g. I and heated 7 hrs. on the boiling water bath, give, after removal of the AcOH from the ether soln. with H_2O and NaOH and the I with $Na_2S_2O_4$, 280–300 mg. of the *γ-formyl deriv.* (II) of I, m. 244°; this is extd. with 3.5% HCl; *Cu salt*, m. 203°; *oxime*, red-brown prisms or needles with a red-violet surface luster, m. 277°. Boiling 90 mg. II in 30 cc. Ac_2O and 300 mg. AcONa for 3 hrs. gives the *γ-CN deriv.* of I, needles with a violet surface luster, m. 261°; expts. on the sapon. of the CN group were unsuccessful. The Zn complex salt of II, catalytically reduced by PtO_2 for 4 days, gives a quant. yield of the *γ-hydroxymethyl deriv.* of I, m. 236°, which is extd. from Et_2O with 0.8% HCl. II (600 mg.) and excess HCN in C_5H_5N-Na_2CO_3, allowed to stand 24 hrs., give 450–500 mg. of the *cyanohydrin*, $C_{34}H_{37}O_3N_5$; it splits off HCN on shaking with NaOH or on warming with Me_2CO, MeOH, C_5H_5N or dioxane; on heating in the dry state it also splits off HCN, giving II; sapon. can be effected by satd. MeOH-HCl but a complicated porphyrin mixt. results, from which the γ-glycolic acid has not been insolated in pure form. Isochloroporphyrin e_4 di-Me ester (500 mg.) in 250 cc. glacial AcOH and 3 g. AcONa, treated with 1 g. I and heated 3.5 hrs. on the boiling water bath, give 300 mg. (60%) of *di-Me pyrroporphyrin-γ-glyoxylate*, $C_{36}H_{38}O_6N_4$, plates with a violet luster, m. 248°; catalytic reduction with Pd-$BaSO_4$ in 100% HCO_2H at 65° for 9 hrs. gives 55% of *di-Me pyrroporphyrin-γ-glycolate*, $C_{36}H_{40}O_4N_4$, dull green prisms, m. 278°. Catalytic reduction of II with Pd in 100% HCO_2H for 16 hrs. at 65° gives I. Reduction of 350 mg. of pheoporphyrin a_5 di-Me ester (III) in 100% HCO_2H with Pd at 55–60° for 16 hrs. gives 80 mg. of the *desoxo compd.*, with a steel-blue reflex, m. 289°; with Pd-$BaSO_4$ the yield is 100 mg. The 10-Ac deriv. of III under similar conditions appears to give 10-acetoxydesoxopheoporphyrin a_5; in cold 100% HCO_2H there results 9-hydroxy-desoxo-10-acetoxypheoporphyrin a_5. C. J. West



Chlorophyll. XCIV. Protochlorophyll and vinylporphyrins. The oxo reaction. Hans Fischer and August Oestreicher. *Z. physiol. Chem.* **262**, 243–69(1940); cf. preceding abstr.—*Protopheophytin* (I), m. 144–6°, was prepd. as a dark green amorphous substance by reaction of vinylpheoporphyrin a_5 Me ester and phytol in pyridine and $COCl_2$. It was also prepd. from pheophytin by the action of Fe powder in Me_2CO and HCO_2H as solvents. Mg was introduced by the use of EtMgBr and the product decompd. with PrOH and boiling with I. The resulting vinylpheoporphyrin a_5 phytol ester phyllin (protochlorophyll) differs in spectrum from a natural prepn. of protochlorophyll. This was shown to be due to the latter being a mixt., for on treatment with Mg as above the product was identical with that of the synthetic material. It is suggested that the material which is present in the rind of gourds from which the natural product was obtained is a mixt. of I and its phyllin. *Vinylpheoporphyrin-b_5-3-methanol di-Me ester*, m. 269°, was prepd. by the treatment of methyl pheophorbide b_5 oxime with Fe powder in 80% HCO_2H and esterification with CH_2N_2. Treatment of rhodine g_7 tri-Me ester oxime with Fe and HCO_2H similarly reduced the oxime group to a methanol and the product was *vinylrhodinporphyrin-3-methanol tri-Me ester*. Improved methods for prepn. of chlorine e_6, rhodine g_7 and phytol from pheophytin a + b are described. Treatment of vinylchloroporphyrin e_6 tri-Me ester (II) in HOAc with HI gave 2-α-hydroxychloroporphyrin e_6 tri-Me ester (III), m. 247°, the HI having added to the vinyl group and then hydrolyzed. Dehydration by heating of III gave II again. HBr also could be used instead of HI. Similar treatment of vinylphylloerythrin mono-Me ester gave *2-α-hydroxyphylloerythrin mono-Me ester* (IV), m. 284–6°. Oxidation of IV with I_2 in HOAc gave *oxophylloerythrin* which could be catalytically reduced to IV. Vinylpheoporphyrin a_5 di-Me ester is converted to *2-α-hydroxypheoporphyrin a_5 di-Me ester*, m. 285°, by HI. *Vinylchloroporphyrin e_4 di-Me ester* (V), m. 253°, was obtained from chlorine e_4 di-Me ester by treatment with Fe and HCO_2H. V was also obtained from II by long heating in HCO_2H. V was converted to *vinylchloroporphyrin e_5*, does not m. 320°, by treatment with I_2 and KOAc in HOAc. Vinylpheoporphyrin a_5 was obtained from pheophorbide a by treatment with oxalic acid and Fe in acetone instead of the usual HCO_2H and Fe treatment. The mechanisms of the

reactions are discussed. Cu complex salt from acetyl-chlorine C_6 tri-Me ester, m. 198°; Fe complex, m. 176–8°; Mn complex, m. 170–3°. Milton Levy



A reaction of hydroxamic acids. Martin Schenck and Leopold Wolf. *Ber.* **73B**, 25–8(1940).—It had been found (*C. A.* **34**, 1677[6]) that by a series of transformations there can be obtained from cholic acid a nitroketolactamtricarboxylic acid (α-acid) $C_{24}H_{34}N_2O_{10}$ which can be represented by formula I (R = $CHMeCH_2CH_2CO_2H$) (only the positions of the NH and CO groups of the lactam ring are uncertain; they may be the reverse of those shown). Hot 90% H_2SO_4 rearranges I into a β-isomer (II) (or possibly II with —C(:NOH).O.CO— instead of —CO.N(OH).CO— in ring B). Among other differences, I and II behave differently toward alk. $KMnO_4$; both are oxidized but I evolves no gas while II gives a considerable amt. of a colorless gas consisting chiefly of N. Hydrolytic cleavage of the lactam rings of I and II gives amino acids which on $KMnO_4$ oxidation behave like the parent I and II. To elucidate the mechanism of the gas formation a no. of N-contg. derivs. of bile acids, with the N in the form of amino, ketoxime, lactam and hydroxamic groups, were treated with alk. $KMnO_4$. Of these, all but the hydroxamic acids gave either no gas or only traces. Among the compds. studied were a hydroximinoketohydroxamic acid $C_{24}H_{36}N_2O_8$ (III) and a diketohydroxamic acid $C_{24}H_{35}NO_8$ (IV = III with C:O instead of C:NOH in ring B) (in these compds. the positions of the CO_2H and HONHCO groups may be the reverse of those shown). III gave in addn. to N a considerable amt. of a gas relatively quite sol. in water (presumably N_2O) while IV apparently gave only little N_2O along with the N. Under the same conditions aceto- and benzohydroxamic acid (V) gave chiefly N_2O with apparently only little N. The evolution of gas seems to be a general reaction of hydroxamic acids. That II also evolves gas although it contains no free hydroxamic group is easily explained, for in ring B there is an anhydride-like union of a hydroxamic with a carboxyl group which is opened by the alkali and the resulting hydroxamic acid then reacts with the $KMnO_4$. Hitherto the relative amts. of N_2O and N in the evolved gases had been detd. only roughly. In the present work the gases evolved by II and V were analyzed quantitatively and found to consist of N + 1.5% O (II) and 96% N_2O + 4% N (V), resp.

C. A. R.

Estrogens with oxygen in ring B. II. Δ⁶-Isoequilin from 7-hydroxyestrone. W. H. Pearlman and O. Wintersteiner. *J. Biol. Chem.* **132**, 605–12(1940); cf. *C. A.* **34**, 112[6].—7-Chloroestrone benzoate was obtained from 7-hydroxyestrone 3-benzoate by treating it with PCl_5 in $CHCl_3$ with $CaCO_3$ as acid-binding agent. Elimination of HCl from this Cl deriv. was effected by heating in C_5H_5N contg. NaI. Removal of the Bz group by alk. hydrolysis gave Δ⁶-isoequilin, a new isomer not identical with the isoequilin of Inhoffen (*C. A.* **31**, 4984[4]). Unlike equilin it yields estrone on catalytic reduction and possesses about 1/8 of the physiol. potency of estrone. Δ⁶-*Isoequilin* m. 265–6° (all m. ps. cor.), $[\alpha]_D^{25}$ 150° (0.98% in dioxane); *acetate*, m. 140–1°; *benzoate*, m. 202°.

A. P. Lothrop

Steroids and related compounds. V. Steroid diosphenols. V. A. Petrow and W. W. Starling. *J. Chem. Soc.* **1940**, 60–5; cf. *C. A.* **33**, 7812[1].—*cis*-Δ⁵-Cholestene-3,4-diol dibromide (Rosenheim and Starling, *C. A.* **31**, 3934[2]) (10 g.) in 60 ml. C_6H_6 is shaken with 2.5 g. CrO_3 in 30 ml. H_2O and 60 ml. AcOH for 3 hrs. at room temp. and the C_6H_6 layer treated with 5 g. NaI in 40 ml. EtOH; after the I is removed by 2 *N* Na_2SO_3, ether is added, the acid extd. with 5% aq. Na_2CO_3 and the C_6H_6-Et_2O layer shaken with 20% aq. KOH, giving the bright yellow K salt at the interface; the aq. layer is run off, the ether layer decanted and the K salt washed by decantation with Et_2O; the salt is then suspended in Et_2O and acidified with 2 *N* AcOH; crystn. of the residue from aq. Me_2CO gives 1 g. of pale yellow Δ⁵-*cholestene-3,4-dione* (*form A*) (I), with 0.5 mol. of H_2O of crystn., m. 135–6° (m. ps. cor.), $[\alpha]_D^{25}$ 30.5°, $[\alpha]_{5461}^{22}$ 41.3° (all rotations in $CHCl_3$); I gives a yellow color with $C(NO_2)_4$ in $CHCl_3$ and a purple color with $FeCl_3$. Refluxing I and *o*-$C_6H_4(NH_2)_2$ in abs. EtOH for 1.5 hrs. gives the *quinoxaline deriv.* (II), m. 175°; with Brady's reagent in EtOH there results the *mono-2,4-dinitrophenylhydrazone* (III), dark red, m. 255°. I and Ac_2O in C_5H_5N (12 hrs. at room temp.) give 4-acetoxy-Δ⁴,⁶-cholestadien-3-one (IIA), m. 160–1°, $[\alpha]_D^{25}$ 14°, $[\alpha]_{5461}^{25}$ 17.4° (*c* 1.10); this also results from debromination of 4,5,6-tribromocholestan-3-one (Inhoffen, *C. A.* **30**, 6386[6]). Oxidation of I with H_2O_2 in EtOH-KOH gives Diel's acid, $C_{27}H_{44}O_4$, m. 290°. *cis*-Δ⁵-Cholestene-3,4-diol (50 g.) and 13 ml. Ac_2O in C_5H_5N (12 hrs. at room temp.) give 37 g. of *cis-3-acetoxy*-Δ⁵-*cholesten-4-ol* (IV), m. 193–4°, $[\alpha]_D^{25}$ −64.5°, $[\alpha]_{5461}^{22}$ −75.3° (*c* 0.9260); shaking with CrO_3 in C_5H_5-AcOH-H_2O 6 hrs. at room temp. gives 9.5 g. (from 20 g. IV) of *3-acetoxycholestan-4-one 5,6-oxide* (V), m. 173–4°, $[\alpha]_D^{25}$ 3.8°, $[\alpha]_{5461}^{20}$ 4.5° (*c* 1.116); it does not show selective absorption in the ultraviolet region and gives no color with $C(NO_2)_4$; the corresponding *Bz deriv.* m. 185–6°, $[\alpha]_D^{25}$ 6.4°, $[\alpha]_{5461}^{22}$ 9.3° (*c* 1.186 in C_6H_5; inactive in $CHCl_3$). Refluxing 100 mg. V in 2 ml. AcOH contg. 200 mg. AcONa for 1 hr. gives 70 mg. of Δ⁵-*cholestene-3,4-dione* (*form B*) (VI), m. 162–3°, $[\alpha]_D^{25}$ 57.3°, $[\alpha]_{5461}^{22}$ 85.4° (*c* 0.726 in C_6H_6); it gives an intense orange-red color with $C(NO_2)_4$ in $CHCl_3$ and a violet color with EtOH-$FeCl_3$ and shows an intense ultraviolet absorption at 3200 A. VI also results in 0.5 g. yield by refluxing 1 g. V and 2 ml. concd. HCl in C_6H_5-EtOH for 1 hr. or by warming I with AcOH-HCl. The mono-2,4-dinitrophenylhydrazone (warming on the steam bath for 3 hrs.) is identical with III; the quinoxaline deriv. is identical with II but is formed by heating the components at 150° for 30 min. The K salt is obtained by shaking the ether soln. of VI with 20% KOH; AcOH regenerates VI. Oxidation of VI with H_2O_2 gives the 7-keto-"Diel's acid." VI is evidently identical with the compd. obtained by debromination of 4,4',5,6-tetrabromocholestan-3-one. VI does not yield an acetate with Ac_2O (with or without AcONa). IV (10 g.) with Br in AcOH-$CHCl_3$ gives 9.7 g. of the *dibromide*, m. 115°, which decomps. on keeping; shaking 5 g. in C_5H_5 with 3.3 g. CrO_3 in dil. AcOH for 6 hrs. at room temp. gives 2.5 g. of *3-acetoxy*-Δ⁵-*cholesten-4-one* (VII), m. 123–4°, $[\alpha]_D^{25}$ −76.7°, $[\alpha]_{5461}^{20}$ −93.8 (*c* 1.058); refluxing 500 mg. VII in 5 ml. Ac_2O for 1 hr. with 500 mg. AcONa gives 400 mg. of *3,4-diacetoxy*-Δ³,⁵-*cholestadiene*, m. 128°. VII shows an absorption band at 2800 A. VII with EtOH-HCl or with EtONa in EtOH gives cholestane-3,4-dione (VIII), m. 149–50°, $[\alpha]_D^{25}$ 79.7°, $[\alpha]_{5461}^{18}$ 94.5° (*c* 1.208); EtOH-$FeCl_3$ gives a violet color; quinoxaline deriv., m. 208–9°; *mono-2,4-dinitrophenylhydrazone*, dark red, m. 252–3°; Ac_2O-AcONa gives the enol-acetate (IX), m. 102–3°, $[\alpha]_D^{25}$ 92.5°, $[\alpha]_{5461}^{18}$ 100.5°. Oxidation of VIII with alk. H_2O_2 gives cholestane-$C_4\|C_4$-diacid (dihydro-Diel's acid), m. 247–8° (di-Me ester, m. 126–7°). An isomeric form of VIII could not be prepd.; regeneration from the phenolic K salt by AcOH and alk. hydrolysis of IX or of VII yield the same VIII; this suggests

that only 1 of the CO groups, presumably that at C_4, is able to undergo enolization and that VIII exists in the stable enolic form, Δ^4-cholesten-4-ol-3-one, only. V, refluxed with Ac_2O-AcONa for 1 hr., gives IIA. V (1 g.) in Et_2O-EtOH and 2.5 ml. *N* EtONa, acidified with *N* HCl after 1 min., gives *$\Delta^{2,6}$-cholestadien-3-ol-4-onyl-6,6'-($\Delta^{4',6'}$-cholestadien-4'-ol-3'-one* (X), m. 239–40°, $[\alpha]_D^{25}$ 23.7°, $[\alpha]_{546.1}^{20}$ 30.1° (*c* 1.12); it contains 1.96 atoms active H; the ultraviolet absorption spectrum shows max. at 2750 and 3100 A., log ϵ 3.9 and 3.8; *mono-2,4-dinitrophenylhydrazone*, m. 248° (decompn.); *diacetate*, m. 205–6°, $[\alpha]_D^{25}$ −52.4°, $[\alpha]_{546.1}^{20}$ 60.8°.

C. J. West

Brassicasterol. II. Degradation by ozone. Erhard Fernholz and Homer E. Stavely. *J. Am. Chem. Soc.* **62**, 428-30(1940); cf. *C. A.* **33**, 1747[3].—Whereas previous work did not decide between the C_{28} and C_{29} formulation for brassicasterol (I), expts. with O_3 favor the C_{28} formula. Brassicasteryl acetate (II), treated with 1 mole of Br and then with twice the theory of O_3, gives *β*-3-hydroxybisnorcholenic acid, $C_{22}H_{34}O_3$, m. 293° (decompn.); *Me ester*, m. 139-40° (*Ac deriv.*, m. 138°). The action of O_3 upon II in AcOH gives a slightly racemized 1-methylisopropylacetaldehyde, whose semicarbazone m. 119°, $[\alpha]_D^{25}$ −39.4 ± 2° (8.65 mg. in 2 cc. EtOH); the aldehyde from ergosterol m. 128°, $[\alpha]_D$ −52°. Thus I is 7,8-dihydroergosterol. The tetrabromide of II with NaI gives the *22,23-dibromide* of II, m. 236–8°. Ergostanol gives a *m-dinitrobenzoate*, m. 202-3°, $[\alpha]_D^{25}$ 14° (12.7 mg. in 2 cc. $CHCl_3$). C. J. West

Partial synthesis of corticosterone. I. Purnendu Nath Chakravorty and Everett S. Wallis. *J. Am. Chem. Soc.* **62**, 318–20(1940).—3-Hydroxy-12-ketocholanic acid forms a *Me ester*, m. 143°; the Ac deriv. (I) m. 197°. I in $CHCl_3$ or AcOH contg. a little HBr gives a bromide, a sticky red residue, which with boiling EtONa in abs. EtOH yields *3-hydroxy-12-keto-9,11-cholenic acid* (II), m. 172–3°; the absorption at 242.5 is characteristic of *α,β*-unsatd. ketones; the Ac deriv. of II m. 199°. Dehalogenation with Zn and AcOH gives 3-hydroxy-12-ketocholanic acid; AcONa and AcOH did not give II. II forms a *semicarbazone*, m. 221°, after 2 hrs.' boiling. Reduction by heating with EtONa at 180° for 15 hrs. gives *3-hydroxy-9,11-cholenic acid*, m. 183–4°, $[\alpha]_D^{25}$ 27° (63 mg. in 5 cc. abs. EtOH); the epimer is removed by crystn. from Me_2CO. C. J. West

Preparation of $\Delta^{4,6}$-cholestadien-3(β)-ol. Vladimir A. Petrow. *J. Chem. Soc.* **1940**, 66–7.—The prepn. of $\Delta^{4,6}$-cholestadien-3(*β*)-ol (I) has been claimed by Dane and Wang (*C. A.* **31**, 6668[9]) who obtained it by debromination of cholesteryl dibromide but it appears from the present work that their product was largely contaminated with cholesterol. Reduction of 20 g. of $\Delta^{4,6}$-cholestadien-3-one (II) (Dane, Wang and Schulte, *C. A.* **31**, 2606[6]) with (iso-PrO)$_3$Al in iso-PrOH (slow distn. for 10 hrs.) gives 11.5 g. of a pale yellow product which, recrystd. repeatedly from aq. Me_2CO, gives the *addn. compd.* of I and its epimer, $C_{27}H_{44}O$, m. 113°; a digitonin (III) estn. showed that it contained equimol. amts. of the 2 isomers. Refluxing 9 g. of the reduction product and 15 g. III in 1900 ml. EtOH for a few min. and allowing the soln. to stand overnight at 0°, washing the ppt. with ether, dissolving in 300 ml. C_5H_5N, adding a large vol. of ether, filtering the III, washing the ether with H_2O and crystg. the residue from aq. Me_2CO gives I, m. 126–7°, $[\alpha]_D^{25}$ −38°, $[\alpha]_{546.1}^{20}$ −38° ($CHCl_3$, *c* 0.954); the digitonide m. 224–7°; Ac_2O in C_5H_5N (12 hrs. at room temp.) gives the *acetate*, m. 78–9°, $[\alpha]_D^{25}$ −71.6°, $[\alpha]_{546.1}^{20}$ −61.2° ($CHCl_3$, *c* 0.960); the ultraviolet absorption spectrum in EtOH shows a broad band at 2390 A., $E_{1\,cm}^{1\%}$ 615; catalytic reduction yields cholestanyl acetate. I also shows a band at 2390 A., $E_{1\,cm}^{1\%}$ 563. Oxidation of I with Oppenauer reagent gives II, characterized by the *2,4-dinitrophenylhydrazone*, dark red, m. 231–2°. Irradiation of I did not yield a compd. with vitamin D activity. The "epi-fraction" forms a yellow oil, from which a cryst. product could not be isolated; as the ultraviolet absorption spectrum in cyclohexane shows a band at 2740 A., $E_{1\,cm}^{1\%}$ 157, and a subsidiary band at 2380 A., $E_{1\,cm}^{1\%}$ 130, dehydration has apparently occurred in the course of its isolation with the formation of a cholestatriene.

Polymerizing ölefins. Ambrose McAlevy (to E. I. du Pont de Nemours & Co.). U. S. 2,183,503, Dec. 12. An olefin to be polymerized, such as C_2H_4, C_3H_6 or iso-C_4H_8 is brought into contact with a liquid catalyst contg. BF_3 1 and water 1.0–2.2 mols. (suitably under high pressure).

Polymerizing ethylene for the production of a viscous oil. Johann Sixt (to Consortium für elektrochemische Industrie G. m. b. H.). U. S. 2,183,154, Dec. 12. Polymerization of C_2H_4 is effected in the presence of dichloroethane or other solvent of the class of aliphatic liquid hydrocarbons or their chlorination products and of $AlCl_3$ and a quantity of water of 0.5–2.0 mols. per mol. of $AlCl_3$.

Effecting catalytic dehydrogenations, as in producing propylene from propane. Herbert P. A. Groll and James Burgin (to Shell Development Co.). U. S. 2,184,234, Dec. 19. A dehydrogenatable hydrocarbon contg. at least 2 C atoms is brought into contact with a catalyst contg. oxides of Al and Cr (with a preponderating proportion of the Al oxide) at a temp. (suitably about 575°)

favorable to dehydrogenation but below that at which substantial pyrolysis occurs (the dehydrogenation being effected in the initial presence of a substantial amt. of added H if desired). U. S. 2,184,235 relates to use of "activated alumina" in effecting similar dehydrogenations. Cf. *C. A.* **34**, 1991[6].

Decolorizing alkyl-substituted aromatic hydrocarbon compounds. John F. Olin (to Sharples Solvents Corp.). U. S. 2,183,405, Dec. 12. For decolorization, a compd. such as crude amylnaphthalene is subjected to a mild hydrogenation by admixt. with an aliphatic monohydric alc., adding a metal, such as Na, capable of replacing H in the alc., and is afterward washed with water.

Amines. Lee H. Clark, John F. Olin and Charles W. Deibel (to Sharples Solvents Corp.). U. S. 2,183,499, Dec. 12. An arrangement of app. is described, and a process of producing amino derivs. of alkanes and cycloalkanes contg. 4–8 C atoms by ammonolysis of a halogen deriv. of the hydrocarbon compd. corresponding to the desired amino deriv., such as amyl chlorides for the production of amyl amines, and sepg. NH_3, together with small quantities of other constituents of the reaction mixt., from the reaction products by distn. Sepd. NH_3 and the other constituents mentioned are absorbed in a lower aliphatic alc. such as MeOH or EtOH, which is a mutual solvent for NH_3 and the halogen deriv., mixing the solvent contg. the absorbed NH_3 and other constituents with a fresh quantity of the halogen deriv. and treating the latter with the NH_3 present in the resulting mixt.

Cyclohexylamine. Johann A. Bertsch (to Monsanto Chemical Co.). U. S. 2,184,070, Dec. 19. A method of prepg. cyclohexylamine by hydrogenation of aniline comprises heating aniline in the presence of a pretreating agent selected from the group consisting of Pb, Pb oxides and basic compds. of Pb at an elevated temp. below the decompn. point of aniline for a sufficient period to suppress the formation of high-boiling compds. that normally result during the hydrogenation of aniline, sepg. the aniline from the agent, and thereafter subjecting the aniline to hydrogenation by contact with H in the presence of a catalyst of hydrogenation.

Alcohol sulfonates. I. G. Farbenind. A.-G. Ger. 684,927, Dec. 8, 1939 (Cl. 12*o*. 23.02). The oxidation products of high-mol. aliphatic hydrocarbons or their mixts. with cycloaliphatic hydrocarbons are so hydrogenated that essentially only the compds. contg. carbonyl groups are converted to the corresponding alcs. while the carboxyl compds. are unchanged. The alcs. produced are sulfonated in known manner, neutralized and extd. with water-insol. solvent.
